- develop and implement the Education Communications Network (ECN) arid get access to the Internet.

Getting access to the Internet is crucial for giving the youth in our country opportunity to use information technologies for their activities in the information technology age and to benefit from the collective knowledge of the planet.

The Internet is to play an important role in solving educational problems in Georgia, particularly in overlooking or newly creating text-books, curriculum programs, instructional materials. Using the Internet services we are planning to take part in selected international communication projects to support the education and get access to diversity of educational and decision support information.

We are planning to connect workstations within the Main Center, Regional Centers and Pilot Schools into LANs and install links to the Internet provider. The components and tasks include the design and implementation of the ECN from the Main Center to Regional Centers and Pilot Schools. We arc planning to provide for students from Regional Centers and Pilot School;, with practical knowledge of the ECN operations and to train specialists, educators and students from Regional Centers and Pilot Schools to become competent the Internet/E-mail users. For this purpose regular introductory workshops for specialists and educators "Internet /E-mail in Education" will be orginized at the Main Center.

We look at the development of the ECN, using Regional Centers' facilities, as an efficient tool for solving problems of the population, who are more than others cut from updated information and educational sources.

The ECN will provide for users from Pilot Schools the possibility to interface with each other for working together on common projects, designing and implementing educational software, publishing textbooks and instructional materials.

The Government of Georgia supports the project, because the introduction of information technologies into the education system is crucial for the development of our country.

The original is presented in English

CAN THE EDUCATION SAVE THE WORLD ?

Predrag Pale

DEPUTY MINISTER OF SCIENCE, MINISTRY OF SCIENCE AND TECHNOLOGY OF REPUBLIC OF CROATIA

ABSTRACT

Human society as we know if is heavily knowledge based. Information technology (IT) is a revolutionary step in development of the mankind, changing the way we live and work, changing our future. Education is key element in preparation for the world we live in and the world of tomorrow. Education is being transformed under influence of IT. High speed of penetration of IT in everyday's lives, ifs unprecedented speed of change and enforceable implications on our future pose a significant problem. Situation is created in which great power is "at the fingertip" of a vast number of non-professional individuals and their every act of misuse or merely a mistake amplifies, multiplies and spreads around the world in a fraction of time in which a handful of officials in charge of privacy and security can hardly notice a problem, certainly not understand or solve it. This indicates that information and legal technology can not efficiently countermeasure those problems and threats. Another, global approach is required. It is suggested that only education, and thorough re-examination and redefinition of fundamental values of our civilisation might offer a solution to this rapidly growing problem threatening to bring end to the world, at least the world as we know it.

THE KNOWLEDGE

The human kind has reached the point in which it completely conquered the nature. It can produce sufficient food to feed the entire population, it can prepare shelter that can resist flood, fire, wind, earthquake and other natural threats. It can live in the highest and deepest, coldest and hottest places, even in the space. It can transmit its perceptions or ideas to just any place in the world and store the entire knowledge of the race for eternity. It can fight most of deadly diseases and has no other natural enemy. The only threat that is shadowing it comes from its own members: people and groups they form.

This achievement, unknown for any other living species, has been done by only one technique and only one methodology: conservation of knowledge and educational process.

Being able to store knowledge and ideas and thus save them from fading away or changing with disappearance of the living person enables each generation to make a new step avoiding most mistakes of ancestors.

Being able to communicate findings, ideas and experience enables cooperation and team work in order to achieve goals beyond capabilities of a single individual.

The modem world is getting increasingly complex even from the aspect of a common citizen. In order to survive, the knowledge rather than physical properties of an individual have the key role. Even more, it is no longer sufficient to reach certain level of education, permanent, lifelong education is required. In the future it will be even more the case. Worse, the speed of changes in the world that surrounds us and the required speed of acquiring new knowledge is challenging the limits of human brain. Therefore, our ability to consume necessary information and adopt the knowledge will determine our chance of survival. This is equally true for each individual as the society in general.

THE INFORMATION TECHNOLOGY

The most important milestones in development of human society are technological changes which influenced the way we store and disseminate our knowledge. The invention of writing, printing machines and telecommunications are the most important milestones in the history. The latest milestone is still not finished (nor it will ever be). It is the information technology (IT). It encompasses the means to store, search and process information and knowledge and the means to disseminate them to just any place in the world (and beyond).

The key properties of IT which enforce changes in almost every type of human activity are the ability of individual to send any information, idea or experience to any number of other individuals anywhere in the world without intermediary as well as to acquire any information.

The benefits of IT are so powerful that no one and no activity can resist it. It is penetrating even the most conservative circles or professions and the speed with which it happens is accelerating.

Thus, we are creating the world which will be dominated by information and everything that exists will exist in this Cyberspace first. Some things will not even exist in material world.

However, the greatest influence of all is in the field of education.

THE EDUCATION

Education is the process of adopting the knowledge and experience of ancestors. At least this was until recently. Today, ever growing importance in education gains the need to acquire the knowledge and experience of contemporary people.

Traditional role of teacher as the information giver and skills trainer is fading away. Today, the stress is on teaching students the way of reasoning.

IT makes it possible to create educational software which will give us the picture and voice of a human teacher, his knowledge, experience and skills. This will be not only the best expert in the filed he or she teaches but he will be the one that presents his knowledge in the way most suitable for the exact student. Student will be able to choose the depth and course of educational process and the teacher will be able to examine the student and to repeat some subjects or even take another approach, of explanation based on mistakes the student made. Finally, the student will be able to measure the level of his newly acquired knowledge against other people in the world. Student will be able to repeat or continue the educational session at any level or course he or she might find necessary or interesting at any point of time. The courseware will be continuously modified and updated according to the latest achievements and findings.

The role of human teachers will shift towards taking care of student as a whole person, choosing and recommending the most suitable courseware and leading discussions and providing help in the matters not covered by auto-educational courseware.

Thus, we can expect that educational process and technology will be thoroughly changed in the future. How soon will this happen is difficult to predict. It has already started, but the main problem is the speed with which teachers can adopt new technologies and their new roles.

In the same time, today's educational systems have to teach us how to use new IT and implement it in our lives and work. Even more, it has to teach us some new fundamental values, ethics and behaviour to prepare us for the Cyberworld.

THE DANGER

The change of the world as we know it has begun and nothing can stop it. There are huge benefits of it: saving of energy and materials of all kinds and thus reduction of pollution, the best service and solutions for individuals world-wide, faster exchange of everything between humans, greater influence of individuals to developments and actions of society and many more.

However, there are problems, too. There are two main directions of problems: speed of change of IT and bringing the great power to the large number of individuals.

IT is generating new services and sub-technologies every few hours. Existing ones are continuously modified and updated. Applications are numerous. The market economy requires products to be delivered to users as soon as possible. It is impossible to wait for products to be extensively and thoroughly tested and verified. Thus the world (and cyberworld) are full of products which have numerous flaws, bugs, side effects, undocumented features and untested options. The combinations of products create even greater reliability and security problems in environments where they are used. Therefore, it is impossible to create safe and secure, highly reliable systems. At least it is impossible for the most of applications. Secure islands are possible to create at very high cost of maintenance and incompatibility with ever-changing surroundings.

The specific property of IT is that its nature is to try to reach as many individuals as possible and to be used by them. Simultaneously they (people) are mutually interconnected and in possession of mental amplifier: the PC. This enables them to let their idea be executed by much faster device (a PC) and multiplied over the network. The consequence is that the results or side-effects of such use or misuse will spread throughout the world (not only the cyberworld) in fractions of time required by other people to comprehend what is happening. This simply means that a handful of authorities (system administrators, police, army, intelligence etc.) has no chance of detecting and comprehending "attack" and then finding and performing countermeasures. Especially, the number of attackers is several orders of magnitude higher than the number of defenders. The key problem is that the attackers have all time they need to invent the attack strategy and mechanism. However, when they launch the attack, the defenders have to compete with the speed of computers and the network to respond.

This situation is further complicated with the fact that it is very difficult to differentiate "good guys" from "bad guys" and legal from illegal. Since new services and applications reach users with enormous speed, they rarely have the chance to study them, their side effects and ethics of their usage. Therefore, a "good guy" with innocent intentions might find out that he did unrecoverable damage to somebody somewhere without even knowing it might happen.

This is the real and threatening danger. Everybody is potential attacker and every action is potentially dangerous. It is obvious that this problem cannot be solved by information or legal technology. It is not possible to define what is legal, and even if it were, it is not possible to effectively enforce the laws. As well, it is not possible to make majority of systems safe.

The order to find a solution the best would be if we would imagine that perfect telepathy is possible today: everybody can read everybody's mind and send him any message even against the recipients will.

THE SOLUTION

Obviously, there is no solution to this problem. At least not in the western civilisation as we know it. IT will bring an end to the civilisation. The only remaining question is whether human kind will find a way to survive.

There is a possibility. The legal and information technology cannot help in the world in which I can do whatever I wish if it is not forbidden or if they cannot catch me. The world in which I will survive if only I can outperform the competition. The problem is in fundamental values of our society. It is based on competition.

The only solution for survival of human race is in change of its fundamental values. Shifting towards co-operation, not competition. Understanding that if I want to survive, I have to co-operate and help others to survive as well. Understanding that I am the one to take care about my own actions so that they do not harm anybody.

This shift can only be accomplished by changing the educational system. Education has to prepare our children and us, adults, for cyberworld and for this danger. It has to teach us not only how to master new IT, but especially how to behave and how to cooperate. There are new rules, and they are gathered around a single word: co-operation.

It is difficult to say whether it is possible to achieve this change and whether there is hope. Unfortunately, there is not much time left for the action.

However, the major step will be made if we understand that it is not the question of morality, ethics, code of honour or similar humanistic value. It is the question of survival.

TOMORROW' 98: COMPUTERIZATION OF THE EDUCATIONAL SYSTEM

Yaffa Vigodsky
DIRECTOR, SCIENCE & TECHNOLOGY DIVISION,
MINISTRY OF EDUCATION, CULTURE & SPORT (ISRAEL)

PROGRAM FOR COMPUTERIZATION OF THE EDUCATIONAL SYSTEM

The program for the computerization of Israel's education system, a five year plan, is being run by the Science & Technology department of the Ministry of Education. The program, whose goal is to computerize the entire school system by 1998, has made considerable inroads since its start in 1994. Today, the results of its applications are becoming renown world wide.

RATIONALE

The program is based on reports submitted to the Ministry of Education and Culture, and has been run by the Ministry, the National Lottery and local authorities since 1994. The complete program was designed in wake of the "Tomorrow '98" report, which discusses the need for science and technology studies at all age of Israel's entire educational system. This report on the computerization program contains very important recommendations which integrate a number of subjects related to science and technology studies, as well as science and technology as a subject in itself.

The implementation portion of the computerization program based on the concept that the school system must be computerized with a ratio of one computer station for every ten students, as compared to previous years. This is a multi-perspective program which includes, not merely the insertion of isolated aspects into the school system, but a complete program, "computerization basket" which includes material and equipment, the creation of computer software and courseware, and a pedagogical format which ensures the assimilation of computerization within the schools as an integral part of the teaching and learning process, and not as a separate entity.

GOALS

One of the main goals of the computerization program deals with the creation of a learning environment rich in technology, very different from that we have known until now. This environment is intended to narrow the gap between the school and the outside world. Earlier technological infrastructures included very traditional teaching methods, which, in most cases, consisted of chalk and blackboard, plus a few other rudimentary teaching aids.

We believe that by changing the learning environment, we improve the effectiveness of the teaching and learning process. We are trying to change this process to allow each student to reach very high levels in accordance with his abilities, in order to find his greatest potential. Through the use of data banks, the participation of various groups of students and teachers via computer links, and the use of computerized tools, we can improve the effectiveness of teaching and learning. The moment we change our teaching methods, the moment we change the role of teacher from a possessor of knowledge to a guide to knowledge, from one familiar with sources of information to one able to integrate the various disciplines, we actually raise the professional level of the teacher, and change his image and status, both in the eyes of the students, and in the eyes of teacher himself.

PROGRAM ASSIMILATION FROM A MULTI-PERSPECTIVE APPROACH

As I have pointed out, the system's program is different from that we have known in the past two decades. An integrate computerization basket that includes hardware and an entire range of basic equipment necessary, both for the purpose of in-class study, and for the purpose of communication with information centres or external groups. Software and courseware adapted to the curriculum in all the various disciplines of the school system; and guidance, in other words, counsellors and instructors within the pedagogical format to help teachers, principals, coordinators and students assimilate the computer as part of the teaching and learning process.

The program consist of a multiperspective approach which deals with four areas.

The first is the physical infrastructure - the computer labs, as well as the concept behind the construction of the lab in one form or another, the distribution of computers within the classroom, or within the lab, so that the largest number of computers is available whenever a group of students is present. In addition to the lab, there is the communication infrastructure, through which students are able to access data banks and contact information centres, other study groups or teachers.

The second area is technological infrastructure. By this we mean the hardware, whose technical specifications are redetermined each year in light of changes made during the school year while adapting the software to the curriculum.

The third area is the infrastructure of pedagogical support, in other words, the training of the teaching and education staff so they are able to use the computer as a base in their teaching processes; training co-ordinators to help assimilate the program within the school, and a pedagogical support system within the various disciplines of those entering the computerization program.

The forth area is the content infrastructure, which must be adapted to the curriculum, to the study programs which integrate to the use of computers to develop teaching methods different from those we were used to until the advent of the computer as an integral part of the teaching and learning process.

PROCESS OF EDUCATIONAL ASSIMILATION

One of the most difficult, but important, stages in the area of the infrastructure format is a process of educational assimilation. Many countries are now dealing with the issue of bringing the computer into the classroom; in most cases, the program include the hardware, and, in some of the better cases, software and courseware, so as to make the computer an integral part of the teaching process.

The next part of the program is the multi-perspective approach, and the most difficult to implement, is the guidance, pedagogical and educational aspect. Israel's educational system has invested most of it resources in this particular area.

THE STAFF AND THE PEDAGOGICAL SUPPORT SYSTEM

In order to begin the process of assimilating the computerization program, we need to prepare the teaching staff and the support systems of those schools participating in the program.

The personnel which introduces these and other programs into the school must be trained within the educational system, teachers who had certain professional training in integrating the computer into the teaching process. We train these groups of teachers in the processes of guidance, giving them a wide foundation in the field of computerization, and the integration of computers within the various disciplines in the teaching process.

The computer counsellor assigned to a school entering the computerization program. This counsellor guides the school in creating its own computerisation program.

Israel's educational system is still a centralized system. The general concept is dictated to the school, but the school has the right, and perhaps he obligation, to create its own computerization program. The school principal and teaching stuff are those who know the student population, the teachers, the general school credo, and the specific programs best. Together with the counsellor, the practical expert in computerization, they create the school's program.

When the school's computerization program is ready, and has received the approval of the school's computer counsellor, the school can then begin implementation of the program. The program includes the purchase of equipment, software and courseware through the local authorities, as well as the computer guidance training program for teachers, the principal and the entire teaching staff.

The second stage is the training of the teaching staff in various fields of knowledge, necessary, as these teachers had specialized in certain specific disciplines. In the various courses, the can learn how to integrate the computer into their own specific fields. Later, after the computerization program in their school is complete, and the computer counsellor has finished the first stage of guidance, the are the ones to instruct the teachers in other disciplines how to use computer in different fields of knowledge, and how to integrate the various disciplines.

SEMINARS

The third stage consists of seminars for principals, co-ordinators and teachers. The Israeli education system believes that the basic training of teachers in the teaching seminaries, or in the universities, ensures the continuation of a thriving process of education.

We believe that the educational system must change according to need, and that the teachers and principals must, at all times, participate in a wide range of seminars. Only thus can they successfully advance the system, and, of course, themselves.

Computer counsellors are placed to the schools in order to help the teachers. Along wilh the external counsellors, we believe that the each school must have et least one computer co-ordinator, whose role is to be responsible for the infrastructure, allocate computer hours, and organize the general seminars. In the end, this counsellor mast be familiar with all the school's program, and which parts of them can be integrated into the teaching process.

Teachers in the various disciplines participate in a very wide series of seminars, whose format is built according to stages.

The first stage is familiarity with the computer itself. In the more advanced stages, the teachers learn all the programs and courseware related to their field. At an even more advanced stage, they integrate their fields with other disciplines and learn techniques in using data banks, and in conducting dialogue with other groups via the computer, so as to bridge the gaps between different schools, information centres and seminars.

GUIDANCE AND INSTRUCTION CENTRES

The Ministry of Education is not satisfied merely with schools seminars. It believes that the counsellors, principals and teachers need a centre where they can continue the process of training, where they can receive support and guidance, so that any difficulty or new idea can first be examined or tested in the centre, under the supervision of professionals.

These centres are the co-ordinating and operative branch of the program; they implement it by helping formulate programs for the schools, together with the computer counsellor and teaching staff. The centre provides the school with ongoing guidance, expertise, familiarity with new tools, and pedagogical counselling according to each schools specific needs.

DISTRIBUTION OF GUIDANCE AND LEARNING CENTRES

Today, Israel has more than 30 such centres in different parts of country.

DEVELOPMENT OF CURRICULUM AND LEARNING MATERIALS

One of the main goals of computerization program is creation of an environment rich in technology by adapting the curriculum and integrating it with computer. The curriculum is adapted so that the computer is used as a learning aid. Data banks are developed in the different disciplines.

COMPUTER COMMUNICATIONS IN EDUCATION

The educational system supports projects and initiatives which integrate computer communications in teaching, as well as projects which use Internet in educational programs. It is currently supporting a project which uses various methods of computer communications, in conjunction with Israel's telephone company.

PEDAGOGICAL INITIATIVES

So far we have discussed a state program in a centralized educational system, with the option of developing local programs according to the real needs of the school, or of the student population. We encourage different groups to propose pedagogical initiatives, and we test them in various sites within the school system. Most of the initiatives include the integration of new computer communications technology in the teaching process, and experience in teaching methods which use multimedia. In addition to those initiatives which have reached us, we have set up "demonstrations islands" within model schools.

Today the program has 10 models schools, which, along with physical and technological infrastructures, receive all the necessary resources and teaching staff before the initiative is incorporated into the entire school system.

CONTROL AND ASSESSMENT

Each stage in the process of assimilation is accompanied by overall control and assessment, broken down into three stages.

The first stage is control and aid, which includes the support of various authorities in buying equipment and software, in the creation of computer programs, and in reviewing the content of these programs in terms of concept.

The second stage deals with design assessment, including an evaluation of the process of assimilation: examining model schools, guidance courses, and school groups participating in the program.

The third stage deals with assessment conclusions, the assessment of the computerisation program in general, and an examination of the returns within the school system as a result of the program's assimilation.

SCOPE OF APPLICATION

At the present, our greatest achievement has been at the junior high school level, with average ratio of one computer station per every 12 students. The junior high school level has shown the most progress, with a one to ten ratio having been achieved among the majority of the students.

BUDGET

The Ministry of Education has increased its budget tremendously for the computerization program between 1994 and 1996, with a current budget of 80,3 million shekels this year alone. The other contributors to the project, the National Lottery and local authorities, have basically maintained the same budgets for the projects over the past three years.

PROBLEMS AND DIFFICULTIES IN THE PROGRAM

In wake of the rapid technological developments, large gaps between different schools can occur in terms of updating programs and equipment. Therefore, we prefer a slower rate of assimilation, while at the same time, continuing to update equipment and teaching aids.

The computerization program is new, and includes different teaching methods than those used today. Many more hours are required to train a professional and experienced staff, both to train additional teachers and instructors, and to transfer the material to the students.

Because of complexity of the process of assimilating the computerization program, which includes purchasing equipment, training personnel, and supervising the various processes, the rate of assimilation has been slower than anticipated.

FUTURE EMPHASIS

Here is our plan for the next two years of the program. First is the massive development of curriculum, data banks and computer communications to meet the needs of the schools. We also plan to expand computer activities in the elementary and secondary schools, as well as expand the number of initiatives and experiments. Additional model schools will be added to the program, and the guidance and supervisory system will be reinforced.

Discussion

COURSE «INFORMATIONAL CULTURE» IN RUSSIAN SCHOOLS

Yu. A. Pervin

HEAD OF FIRM «ROBOTIAND» (RUSSIA)

Two excellent ideas - the idea of trough continuous education and the idea of early informatic learning - were declared practically simultaneously during up standing of national school informatics [1]. This fact not casual, since both ideas bears on unite fundamental thesis: the main goal of obligatory course of informatics in mass general education school is formation in whole young generation of the country of thinking style, adequate to requirements of complimentary information society.

The idea of early study of informatics develops in our country by two different ways:

• as permanent tendency, according to which the lower threshold of the informational education beginning evolutionally decreases from setting, accepted earlier (in 1985) by the government, concerning the place of informatics in the high forms of secondary school;

• as developing courses starting from bottom, from the primary school (and even from pre-school institutions). The idea of through continuous education, based on the information technologies, becomes now the main orientation in the school teaching organization. The educational system, going for beyond the frames and covering most of school disciplines, is called to form in young generation;

• fundamental knowledge about information, informational processes and models;

• applied skills concerning application of informatics methods and means in different spheres of activity;

• capability to utilize modem information technologies in everyday (educational) activity (search, processing, analysis of information, communications);

• world-conseption view of unit informational pattern of contemporary world.

Such system would be called here "informational education".

The idea of continuous informational education of schoolchildren, appearing more and more actual, finds its practical way of realizing in the active initiatives of regions, which even few years ago were impossible. These ways are open, due to formations in the last time the following prerequisites:

• the most significant one ought to consider the pedagogical prerequisites; since 1985 the teachers have stored a great experience of work in school informatics field, which has principally changed the phsyhological climate in school, formed around school computers, informatics class-rooms, school computer applications;

• in comparison with 1985 year the technological provision of school informatics has changed dramatically; currently in the country practically there are no regions, in which computerized school are absent; the necessity of utilization becomes determining factor in the management of school training process;

• complex of program-methodical prerequisites present a great fund of software and original methodical materials and didactic systems, developed during last decade;

• administrative prerequisites consist the fact, that among the management workers of educational system, plenipotentiary to accept responsible decisions, there appears more and more persons, who comprehend not only managerial, but also didactic possibilities of informatics and computer techniques;

• finally, to set of organizing prerequisites one might add the freedom, presented last years to educational institutes in the field of their time utilization; in particular, we mean so called "regional hour", which the school has right to use according to its own opinion for some problem study, which is most actual for the region.

At such prerequisites the problem of continuous informational education realization may be set and decided in the condition of individual industrial developed region. Such conditions were formed, in particular, in Samarskiy region [2]. Here from the set of regional hour, which In framework of school education is equal to 360-550 hours, there was formed course "Informational culture", called to teach the trainer how to live in the informational society: to be able to plan his own activities, to be able to informatize his activities (including in the first turn the intellectual one), finding each time the most effective tool, to master the skills of typical complementary informational system utilization.

The course has module structure, where each module is interrelated with one of the study years in framework of school education from the first up to eleven form. The module consists of software on the informational carriers, supplied by users instructions, book for schoolchildren (textbook) and book for teacher (collection of methodical comments for each lesson. Some presentation about the course content one can obtain from the following list of its main modules (as for primary school modules the annotation data are presented).

• *First form - Computer is your friend.* Elemental introduction into communication practice with computer. Computer at the lessons of Russian language and mathematics.

The easiest trainers of keyboard and mouse interface. Exercises on direct and backward calculation, the number composition and easiest arithmetics.

• *Second form. Computer sharpness (multitudes, signs and order).* First presentations about multitudes, submultitudes and elements. Appropriateness and other. Classification and constriction. Computer at the lessons of mathematics and Russian language. Games and exercises on classification, memory training and construction.

• *Third and fourth form.* Follow me, robot! Algorithm round us. Computer models.

The ideas of command and algorithm are considered and discussed in detail. The instrumentarium of computer lessons in mathematics is actively used. The idea about users and management methods. Recognition of appropriateness and investigation of algorithms, method of "black box". General scheme of user's investigation. Propedevtic of management structures. Solution of combinator problems and user's construction.

• *Fifth form. Computer and word.* Textual editor: dictations, compositions, wall adders, books.

• *Sixth form. Computer - art instrument.* Graphical editor, computer opening day. Editing of musical information.

• *Seventh form. Elements of programming (on the base of performer Cockroach and Cherepashka Logo).* Procedures, parameters, recursions.

• *Eight form. Informational storages.* Data banks and electron tables.

• *Ninth form. The information coding.* Methods of presentation, storage end delivering of information.

• *Tenth form. Informational models.* Typical applied problems of informatics.

• *Eleven form. Informational technologies.* Expert systems, knowledge bases, table editional systems, communications.

The intersubject connections play a significant role in the course. It's important to show, that in everyday educational activity most actual are knowledge and skills, obtained by learners in the course of informational culture. That is why in the lessons on the course children fulfil exercises on their native language on the computer screens, are introduced to with diverse ecological situations, decide on the computers mathematical tasks from school book of problems. The consequence of basic position of the course in school becomes the development of set of original text-books for children and methodic manuals for the teacher one of the most difficult part of the project "Informational culture".

All the teacher's manuals on the course are edited in the form of methodic comments for each lesson. Module structure, variableness of curriculum and open character of software, included into the course, opens for the teacher, who is searching, the ways of construction of his own lessons, if he would be solid with the main directions and goals of the course.

The books for learners, differ by age peculiarities in each module, may be referred to different genres. For example, manual for first form children is a book-coloring, with which children work in the class-room and at home. The book for the second form present a textbook, in which there were collected either computer of noncomputer logic and combinator tasks. The textbook for third-fourth form may be called as a book for reading (mainly for reading at home).

The main component of each computerized course is its software. In total the course "Informational culture" includes more than 90 programs of different volume and complicity. Computer is included in most of lessons. Though computer studies are not selfgoals, nevertheless in the primary school there are no computerless lessons. Later on, beginning from the eight form, in curriculum there would appear certain lessons, which may be carried out beyond the informatics classroom, while in the eleven form the share of noncomputer study comes up to 20 %.

The methodics of training is primary for arbitrary educational program system, whole its software is secondary. In the course "Informational culture" either assignment or forming of programs, or their successivity are subordinated to one aim - to provide the effective didactic instrumentarium for solution of the main course problems. The base of the educational software consists of program performator's system, each of which is foreseen for the formation, training and fixation of this or that skill. In the younger forms the most of programs-performers are clothed in the form of developing games: in the primary school the game form of activity maintain a vast significance for children. At the same time from the game arsenal battles, killers, vampires are completely eliminated.

In the program of the course the page-by-page reading of the text from the screen is practically absent. A large set of graphical files-illustrations is connected with each problem. A lot of screen pictures are animated. Some programs have sound (musical) following. Most of programs are multifunctional, thus fulfilling in the course several different pedagogical tasks.

At the diversity of programs the designers of software tried to minimize the number of interfaces of different types. This requirement was fulfilled at least inside each individual module. The unity of interface allows to minimize the efforts on mastering of keyboard skills, to focus the learners attention on significant features of the problem, to promote the unity of requirements to knowledge and skills of the learners.

The lesson of informational culture for kiddy as well as every other lesson in the primary school uses a lot of forms: conversation, questioning, games and performances, concourses, opening days and even concerts. However each of traditional forms of the lesson carrying out, apart from its individual aim, which is foreseen by the lesson plan, presents a preparation to combination study moment - computer exercise or laboratory work.

For teacher-user (and first of all for the most nonprepared teacher of primary school) it's important, that most of programs, included into software of the course, are open: the user is able to form data, he needs (the exercises, proof texts, individual conditions etc) by build into the system means, which does not require the capability to program, using some program language.

Program means of the course were prepared for the IBM PC computers. The definite type of the computer doubtless presents a principle technical limitation. The base of selection of this or that type were such contradictional requirements as prevalence, from one side, so workability, adequate to typical industrial contemporary problems, solved with the help of computers, from the other hand. One may surely tell, that antiquated national computers *"Корвет"* and *"УК-НЦ"*, in great quantity present in russian school, don't meet the second of mentioned requirements, whole powerful *Mac* one can't yet refer to widespread in schools.

However, the configuration spectra of school in formic class-rooms with IBM PC machines is quite wide. The course project was forced to orient on modest configurations in order it might be realized practically on all IBM-computers (in particular, on the computers of well known russian-american project "Pilot schools"). The programs may work either in the network or without network, with winchester disks on the learning computers or without them. Most of the programs are tuned on different apportionment of keyboards.

The teacher-user (and mainly most nonprepared teachers of primary school) is completely "screened" from configuration peculiarities of school informatic classroom.

Organizational problems of the course introducing are sufficiently sophisticated. The idea of "enter point" leads to rational solution. The academic year is equal to the enter point, beginning from which one may study the course with no damage of its main concepts and goals.

Base enter. The first enter point - first form.

This is natural start of the course, which, probably, afterworlds would be modified, if in the considered continuous course would be included children, who have been acquainted with computer in the framework of pre-school bringing up.

Temporary (additional) enter point in the second form is intended to make easier the organizing problems, connected, from the one hand, with widespread inculcation of the course in schools of large region, while, from the other hand, with significant term gap between the beginning of study in the first form and transition to secondary, school (fifth form). The schoolchildren from the second form, starting to the study, would meet the problem to overcome relatively not so much supplying of missed skills. The problem becomes easier due to the fact, that great work towards mastering of literacy, which is carried out with the help of computers in the pupils of first form, here practically is not necessary: the contingent of the second form are mostly, as a rule, pupils, who are able to read the text-books. Most of the programs, requiring the perception of textual information, may work in the second form module without additional adaptation.

The second enter point - the fifth form.

Children start to the introduce to informational culture directly from the text processing - the main form of computer information process in the contemporary world. The necessary ideas concerning algorithm, performer, command, system of commands may be supplied a little bit later, on the next circle of didactic spiral.

In organization plane the fifth form present a special and very appropriate enter point. In the connection with the transition to secondary school with its multisubject education it's appears a possibility to charge the leading of the course to the most ready category of teachers - professional in informatics teachers.

The third enter point - the ninth form.

The beforehand requirements to learners, which come to the ninth form from the point of view of their readiness to accept the course "Informational structure": minimum experience of work with computer, acquaintance with keyboard; experience with program composing of 10-20 line length on arbitrary language. These requirements may be eliminated through carrying out of several primary lessons in the ninth form.

The introducing of the course according to the scheme, close to the described here, started from 1994-1995 academic year in several school of Samara region. Till the autumn of 1995 all the program and methodic works on this course were finished. In Samara there has been stored an experience of teacher's training to teach the course in school. Since 1995-1996 the course started to be used in several other regions of the country.

The course program, contents and methodics of training had accepted approval and support of Ministry of education of Russia Federation: the textbooks and manuals on the course have been included into federal complect since September, 1996. This means the recommendation of this course for schools from the level of Ministry, as well as governmental support of it inculcation. The leading national methodic journal "Informatics and Education" has expressed a great attention to the course. Since 1995 the journal regularly publicates the materials on the course.

PEDAGOGICAL ENGINEERING AS THE WAY OF THE INTRODUCTION OF NEW TECHNOLOGIES

Alain Chaptal

DIRECTOR IN CHARGE OF PEDAGOGICAL ENGINEERING OF CNDP
THE NATIONAL CENTER OF PEDAGOGICAL DOCUMENTATION
(FRANCE)

A great number of prophets proclaimed a hundred years ago that our system of education would suffer a great shock. Jim Clarke, president of «Netscape Communications» who knows well which way the wind blows, speaking at the forum on the problems of information highways on 1 February last year organized by the French government said, «The most significant impulse which Internet has on our human society will be revealed in the field of education. Within the period of ten years such traditional educational means as books and notebooks will be replaced by interactive tutoring in on-line mode». Thereby he echoed Thomas Edison who said the same many years ago. As a matter of fact, the inventor of phonograph, the outstanding popularizer of new educational technologies proclaimed 83 years ago, back in 1913, «Books will soon become obsolete and will leave educational institutions. Children will study by eyes. All sciences, all fields of human knowledge can be taught by films. Our school system will be completely transformed in ten years' time». Topical character and the recurrence of such declarations are disturbing. It testified to the role played by various prophets and dealers during the whole history of educational technologies from the time they were originated. It is characteristic that these prophecies have never been realized anywhere up to now. Now, as never before, it is essential to bear this in mind and approach these problems with sobriety and humility: not to make such bold predictions even now, in the age of ever increasing complexity and further spreading of network technologies.

LESSONS OF HISTORY

Actually the history of educational technologies testifies of a peculiar pendulum-like movement, periods of enchantment and disappointment following each other. It was a very true observation by Larry Cuben, professor of Stanford University. We believe that it is true not only for America but for France as well, aod probably for the whole civilized world. Everything begins with the first stage, that is delight in connection with perspectives, which a new technology opens for us. It gives a lot of chances for the prophets who urge various executives to experiment in the field. This first stage when researches at universities (at least in the USA) are conducted, which are the evidence of the interest on the part of the educational system to innovations (and they usually state that the results are not worse than when traditional methods are used) is followed sooner or later by a second stage, the stage of disappointment when the objections of the teachers, their complaints about unsolved technical problems, and the difficulty to adapt school curricula to the new technology are heard even more often. The situation is gradually becoming worse and disturbing reports which inform that the new technology cannot find wide application multiply. Then the critical statements against wasting money, organizational miscalculations and the conservatism of the teachers begin to appear. And at last the new technological miracle is buried in oblivion. There is no need to give concrete examples, each of us can present a list of such impressive examples.

The history of educational technologies shows the importance of such factor as management of time, rates of introduction. The rates of introduction of technologies into the process of teaching are just like in forestry, i.e. very slow. But the rates of technological innovations testify, on the contrary, to the increasing acceleration of these processes, about a sharp reduction of time between the development of a new sample and the emerging of the serial product on the counters. This inconsistency between two time scales requires of us to take into account a multitude of new factors, such as the syndrome of engineering scheduled to become obsolete very quickly, in particular. Thus, the institute of advanced, exemplary educational institutions/establishments, equipped in the best technological way are canceled once and for all. Now it is the time for long-range planning of the development of technological park, the constant search for coherence, for the ways how best to combine new computer and multimedia means.

Those who neglect lessons of the past are apt to make the same mistakes. The main idea which arises from all the accumulated experience is as follows: the introduction of the equipment only gives no result, at least it is not enough, it has never been enough and, probably, will never be enough to ensure its application. There is no need to give examples to prove this statement, as well. Any successful strategy requires one to take into account the whole complex of problems, connected not only with equipment, with technology, but with the whole sphere where this technology is introduced and it is assumed that the process of its introduction into the given system of education is understood very broadly. It is absolutely necessary to organize special services to introduce this technology in such a way to ensure their application by the teachers.

It is necessary to underline that any policy in the field based on the considerable increase of expenses is unreal. In this case one should take into account an unfavorable economic situation and the amount of sums already allocated by state budgets for education in the majority of countries all over the world. From now on we should speak about redistribution of the fund to increase the efficiency of their application. Considerable funds have been invested in new technologies by the state practically in all countries of the world the resources of economics being taken into account. But there the lack of coordination insufficiency of control and - if should be said plainly - non-professional approach can be seen.

THE TEACHER AS THE FOCUS OF IMPLEMENTATION

It also becomes quite clear from the history of the development of educational technologies that in France as well as in Europe and the United States the teacher definitely plays the leading role when new technologies are introduced in education. The last report by Software Publisher Association giving the results of a survey of the efficiency of new technologies at schools in 1995-96 states the same. The statement of the fact causes surprise in the first place. Why so little attention was paid to the human factor, why there was so little concern about how to create conditions for psychological adaptation of teachers to this new technology? But at the same time these conditions are crucial for its introduction. One can recall that long before modern photocopiers appeared such «unfriendly» machine as hectograph was used in schools on a large scale simply because it turned out to be an efficient means to meet an important need.

It is the teacher who should be put in the center of any reforms. It is not necessary to frighten him with prospective shocks and revolutions in his customary professional field. It is necessary simply to help him to perform better his usual job. To a certain extent the same approach should be used as wll orgware was first introduced enterprises. When ten years ago it was introduced at enterprises and in offices, nobody declared that due to such means as the text editor, computer mouse or tabulator the jobs done by the secretary, commercial agent or engineer would be different. On the contrary, it was explained that these new means would allow them to do their jobs faster and more efficiently and would free them from boring routine work. In ten years we will be able to assess properly this strategy: it has given impressive results in the sphere of labour organization. Why not adopt the same strategy in the field of education? This is the essence of French and Canadian project «Computerized school» offered by the Ministry of Education of Quebec in 1993. The coordinator on the French side is The National Center of Pedagogical Documentation.

When developing this perspective strategy it is important to understand that the main thing is to offer to the teacher such new means in his professional activities which he could monitor himself, which he could manage to such a degree as to be able to prepare for the lessons better both at school and at home, to illustrate the theme better or to make a better presentation. These new tools should help him to save time, to ensure an individual approach to different students under the conditions of (mass) schools where mixed abilities classes grow in number. It is very important to check up the hypothesis that the best strategy of introduction is a gradual transition from individual mastering of technology and programs by the teacher to the application of the new arsenal of computer and telecommunication technologies in the classroom, instead of rushing at once from the very beginning to introduce the most complicated and interactive technologies and to realize the global projects. Our main problem now is to increase efficiency. One should be aware of the danger of supertechnocrates who try to push their innovations at any cost, let us remember that our professional goal is education, not technological achievements.

Moreover, let us remember that taking into account the large scale of education, the situation of mass communication under which the teaching at schools is conducted, only serial equipment is to be widely introduced, not unique equipment which is the object of dreams of many people. There are no specific technical means of teaching besides perhaps the equipment used in lingaphone rooms. This mass-purpose equipment is simply used for specific teaching purposes. The matter is, that professional requirements to be met by this equipment are very high. They are much higher as compared with usual home appliances because of big pressures on the equipment, the activity of the students, etc. It is better to take a concrete example. Let us compare local computer networks with other computer equipment at schools and enterprises.

In offices and at enterprises this technology proved very efficient. In this case the part of equipment should be uniform at the given enterprise, the number of programs be limited and although each worker can adapt in the best way his working place to his specific job all the elements of the system should be adapted for centralizes management mass servicing and repairs. All the structure is set up and the calculations are made taking into account the factors of economic organization.

The situation is just the contrary at school: the park of equipment is all mixed, program libraries and multimedia means are all different and inflated, various categories of users work on computers, the management of the system and maintenance service are organized poorly, very often non-professionally. The failure of the equipment has different consequences. At an enterprise or in an office this can only result in the waste of time, but for the teacher giving a lesson the failure may have other consequences, the break down (?) of a lesson.

The operation of serial equipment in severe school conditions makes us face the problem of servicing: it is necessary that special gangs (teams, stuff) should be created for the purpose.

PEDAGOGICAL ENGINEERING AND THE POLICY OF COMMON SENSE

Irrespective of deep conceptual differences, underlying national systems of education, it should be mentioned that the accumulated experience of informatization in the field of education multiplies the number of negative invariant situations everywhere: there is too much likeness in miscalculations of information, and it seems to be connected with the very nature of new technologies. It means that the problem of their introduction should be treated seriously if we want to avoid failures.

In view of the above considered factors, The National Center of Pedagogical Documentation, in particular, was reorganized by the decree of the French government in 1992 and the role of this federation of national education institutions, spread all over the country, has been specified. Three tasks where set for the center. The first two tasks are traditional, that is the accumulation and distribution of documentation (and, in particularly, stocking of departamental and regional funds), and also issuing of materials on every possible carrier - paper and paperless, including multimedia means and educational TV programs (every year the National Center of Pedagogical Documentation makes together with Channel 5, educational channel on TV, programs lasting 200 hours which makes about one seventh of the total volume of the programs, produced by the Channel). However, the third task set for the Center is new and it has to do with pedagogical engineering. I have the honor to be the first director in charge of this trend.

The decree, published in «Official Journal» (*«Journal officiel de la République Française* is an official organ printing new state documents of the French Republic) on 11 September 1992 reads, «pedagogical engineering deals with research, development, designing, maintenance of work and evaluation of the efficiency of educational tools». But to explain what pedagogical engineering is one should broaden this official definition.

Pedagogical engineering is far from being regarded as a new theory in education, which is called upon to replace behaviorism or cognitive; psychology. Pedagogical engineering is characterized by pragmatical approach to the above-stated problems, the same as in engineering designing in general. Pedagogical engineering approach these problems taking into consideration all specific conditions ('context') in which they are originated and solved, the specific character of the educational field, it considers technical means of education 'in earnest', that is within the framework of their functions, as the teachers tools, not his substitutes. It includes in the range of the problems which it is to solve such as the training of students to use new information and. communication technologies in their future jobs ('practical' life).

This new task set for the Center should be formulated and solved in view of the three main aspects.

1. *Global approach:* consideration of the problems of new information and communication technologies taking into account all the 'context' of their implementation means that one should take into account the whole complex of parameters in the area into which they are to be introduced, i.e. pedagogical, technical, economic, ergonomic and organizational aspects; it means selection and coordination of such necessary functions as technological monitoring, examination, informing, consultation and support. What I am talking about is the working out of a long-term policy in the area.
2. *Maintenance:* one should proceed not from the projects made by technologists but from the needs of the users, i.e. teachers; this is the specific character of our approach to pedagogical engineering which necessitates to give preference to such projects and technologies which increase the efficiency of the teacher's labour, help him to save time and reduce the expenses or help to ensure an individual approach to his students, and thus to make them to focus of teaching and learning. It is the most difficult thing now, though it is the most important.
3. *Partnership:* The National Center of Pedagogical Documentation and its branches do not seek to monopolize the area. On the contrary, we aim at the development of the partnership with any organization to mobilize all resources both within national and international frameworks which becomes especially important under the conditions of globalization of the market of the given technologies.

This approach makes it necessary for us to devote special attention to such function as distribution of information (first and foremost printed materials), which is the basis of our work. In addition to such well-known sources as our technical reports, informative letters, on-line data bank and, of late, our service in the Web, *«Dossiers de l'ingenierie éducative»* («Proceedings of Pedagogical Engineering») issued to popularize new technical tools and to help teachers to make their choise. Their circulation usually amounts to 16,000 copies, and they are distributed free of charge through the network of regional centers of pedagogical documentation; they are dispatched to local government bodies responsible for the technical equipment of educational institutions, to administrative boards of universities, to appropriate departments of educational districts and to educational establishments. In such brief description pedagogical engineering may appear to have no original approach but simply a set of obvious things at the common sense level. We do not really reject common sense but I would like to remind with connection with reproaches in being banal, how often the reluctance to global approach in solving the problems of the area under consideration resulted in failures. In the same way, the combination of pragmatism with long-term planning often makes one wonder how great will be the effect of this approach? May be, it should be imaginary.

It is best to demonstrate the significance of the global approach, taking into account the area of introduction and the successful combination of various methods of introduction by way of illustrating the development of such area as museumography (though we speak here about the area which is not as extensive or as complicated as education, and this points to the fact how limited these comparisons are). In old days, the function of museums was confined to that of exibiting the works of art. This often led to the situation when an unbelievable number of treasures of art were piled up in one hall, which can be seen at the moment in the Chantilly Museum, whose expositions have not been reorganized according to new approaches and which has remained following the will of the greatest grantor of the museum's collections Duke d'Aumale 'the museum of museums' of the 19th century. But if you happen to visit d'Orsay Museum or the Sainsbury wing of the National Gallery in London, you would be able to appreciate the contribution made by modern museumography in the organization of exposition space, its lighting, you will see that the expositions in which different trends in art are compared are presented in a few fashion, that the routes of the visitors have changed as well as the rhythm of excursions, the whole system of documental maintenance has changed (the work of the documentation centers, book stalls is different now, there have appeared audiovisual documents, etc.). So, the changes should take place in the area of educational technologies: we too often simply «transmitted» them to schools. This is the range of transformations taking place now, this is the way followed by the National Center of Pedagogical Documentation which does not lose sight of pragmatical points.

Let us remain realists: we do not ignore the obvious fact that new information and communication technologies have found a rather limited application in teaching and learning, exept in the area of technical and vocational training, where a considerable park of computers is accumulated (it sometimes consists of hundreds of computers in lycées graduated for universities and technical colleges, and for jobs in the sphere of services). However, in the whole in all developed countries the results of numerous past attempts to introduce new information and communication technologies in the process of teaching and learning (which passes the stages of general enthusiasm about a new 'miracle' and then the stage of oblivion) show that these new technological means which have changed the society, are left outside the area of education. Does it ensure that the situation will be the same in the future?

THE REVENGE OF THE PROPHETS?

Recently a new phenomenon has emerged which makes our forecasts optimistic. For the first time in the history of educational technologies (in any case, as far as mass purpose technologies are concerned which are suitable for teaching any subject, instead of means of narrow application, such as photos or tape recorders) the tools used in the classroom are the same as those which any teacher has or will have at home. The industry of new information and communication technologies is now developing according to the laws of mass demand. If one compares these two facts - the new situation (which is developing rapidly in the direction of using even greater variety of new means in the classroom such as videos for example and others) and the task of improving the quality of education and the efficiency of teaching (about which we spoke earlier) the main line in the development of educational technologies becomes clear, that is to use new tools to help teachers. I think it is necessary to be quite definite in this respect: this very function of new information and communication technologies as teachers' tools and not their substitutes should be given primary importance.

These are the same technologies with the help of which modern community produces and organizes the production of its main riches. And the teaching tools seamed to have become for the first time in the history of mankind the same as the means of production.

From this fact, from all-penetrating integration of tools, from the fact, that the modern change to the digital data in all areas - from education and science to industry, from the general spreading and availability of computer nets and information channels which solves the problem of access to any type of resources the question arises: is it time to look in a new fashion at the statements of the technological prophets which I quoted in the beginning of my speech? Is it not too thoughtless now to treat them with irony especially if we know who made them? Shall we understand these propheses in a new way now? Here is the last quotation - it is also «untimely» prophesy in the spirit of later and well-known prophesy made by Vanevar Bush in 1945 about the appearing of the hypertext. It will make my question clearer. Back in 1912 Edward Thorndike one of the most outstanding American theorists in psychology of education who greatly influenced Skinner and cognitive psychology wrote: «If some technical miracle had given us an opportunity to organize tutoring by books so that the access to the next page would be possible only in the case of the right answer it would make a great variety of educational work which needs the teacher's presence to be tutored only by written materials. Such books should be developed on many subjects with material presented on separate sheets or organized so that the student would not face any difficulties besides the cases of improper usage of the book» .

Today the technological miracle has become reality. At last the means we need are available. Hence a new question is it possible that our predecessors and prophets who despite their mistakes were competent, earnest, firm and who sought the unity of pedagogical art - is it possible that they have made only one mistake namely they were right too early? Maybe their only mistake was that they relied on technologies which were not «ripe», «incomplete» technologies which were unable to fully realize many times revived dream about a technical means which would be simple, available and controllable by the teacher, adapting easily to various conditions and the specific character of subject teaching? How could imperfect tools of that time to satisfy that everlasting need in the means which would make possible on the one hand to organize knowledge resources and make them available and, on the other hand, to take into account every unique teaching situation? In other words were the educational technologies which we have been using up to now - from glass diapositives to educational computer programs of early nineties - and which our predecessors tried to introduce in education, were they not them just unsuccessful and untimely forerunners of what we have got only now?

It may be too early to give a positive answer. In terms of the science these doubts are justified and helpful, they are the pledge of future development but the similarity of the processes in various countries needs a thorough investigation and may discover at some stage of development steady signs of what was predicted long ago namely the renovation of educational process organization and the role of the teacher, and the dynamic redistribution of the roles played by information, experience and knowledge.

The epoch of educational technologies seems to have come at last. However it is clear that without our purposefulness and determination to reconstruct this process on the basis of a global approach, without realization that the help to the teacher must be given the top priority, all our efforts will be in vain just as it was in the past. Now as never before an engineer and pedagogical approach is necessary provide and make it easier the real implementation info the educational process of new information and communication technologies.

THE "NEURONE - STUDENT" IN AN RECONFIGURED EDUCATION SYSTEM

Anne Marrec

DIRECTOR GENERAL,
TELEUNIVERSITY (CANADA)

I would first like to thank you for the choice of the problem of education technology as a subject for the given Commission and for inviting me as a speaker.

It was risky on your part to invite me in this quality since I am neither a technologist nor an educator, but largely an administrator, who dared to have an opinion of her own on the subject — in fact, I am the head of the Teleuniversity, an organization specializing in distance teaching based on the virtual campus concept.

Based on this experience, I am going to discuss the student and the strategy of cooperation in the new communication and information technologies in the education. Let us assume that there is nothing unequivocal in the concept of the student — this concept is equally applicable to the new kindergarten child and to a mature individual attending a university. In relation to the new information and communication technologies, too, this concept is heterogeneous and varies in a wide range, depending on the level of contact of the individual with the equipment available to an education organization, and, more often, beyond it.

In order to clearly outline the subject, I shall focus on the student in contact, or the one, who needs to come in contact with the new communication technologies. This beginning would make if possible for me to illustrate the «Darwinian» evolution of the technophilic student, who at the end of the study process, is somewhat reminiscent of a neuron. Subsequently I shall attempt to state the requirements and the potential of the changes that were introduced into the educational system by this "neurone-student", and also the necessary solutions that are to be envisaged for these changes not to be regarded as problematic.

1. THE ADVENT OF THE "NEURONE-STUDENT"

I shall show the evolution of the student, a graduate from a common school, who faces in his scientific world with the new information and communication technologies as exemplified by fours stages:

1. Origin: *traditional school*

In this traditional school, the relationships between the student, the passive components and the teacher are natural or using the paper or a black or green or white blackboard.

We all have passed through such a school and many of our children also attend it.

2. Transitional Phase: *a Class with Technical Equipment*

The relations in such a school are almost similar to the former one, but there appears a modern and accessible technical equipment in it, as the electronic panel and a printer.

This is the outlook classes in industrial countries are increasingly assuming. At the same time a typical student has an outlet to the world thanks to TV and an Internet subscription.

3. Advanced Phase: *the Class is Connected to the World*

Such classes are few because they are expensive and the teaching aid requirements are high. It seems to open a window to the world thanks to informatics means associated with large networks.

4. Final Stage: *Virtual Open Class*

I so far refer to this model as final because I am unable to predict the future. The physical characteristics in this model disappear and the teacher/student interface and student/student interface has been completely implemented thanks to the multimedia dialog means of distance communication. The distance between the participants is no longer of any consequence, and synchronous and asynchronous use of such means permits overcoming the schedule requirement.

In this world the student is no longer indifferent or passive component, but rather an intelligent component involved in his learning thanks to the choice of and access to different data bases. This regime, which better suits an adult student since it implies a capacity to differentiate and independence, should not be excluded for younger people, who actually use it at home. Conversely, it should be applied at school, gradually developing in the student the ability to independently guide his education. Gradually, the habit of independence makes it possible for him to develop himself all his life, and, consequently, to meet the challenges of the world wfth confidence. However, I am sure that it would be difficult for him to follow the traditional education system along this line — in fact, the logic of development questions its very existence. The effect from the advent of a "neurone-student" is, in fact, impressive but can be controlled.

II. THE EFFECT OF THIS ADVENT ON THE EDUCATION SYSTEM

This advent involves great possibilities and new requirements, and the problems it involves contain solutions.

1. Giddy Opportunities

Today everybody is well aware that new information and communication technologies open up new horizons for the solution to the problems of mass education both in industrial countries, experiencing economic and social crisis, and in underdeveloped countries, which have *overcome external problems.*

In fact, the new information and excommunication technologies:

- eliminate the limitations associated with distance;
- eliminate the need to construct material facilities;
- eliminate the problems associated with the need for time arrangements (the need for coincidence of events);
- *make the teaching process accessible to large numbers* of people, and, hence, make it possible to save the resources of teachers;
- make possible exchanges between communities and cultures, eliminating isolation.

Nowadays these opportunities are only outline, but is everybody aware of the new requirements that they entail?

2. New Requirements

This is now the question of the world which we shall have to transform using new methods; as to the new ethic standards and the new steps to be overcome, they are not only high, but also numerous:

- it is primarily necessary to have efficient equipment;
- it is necessary to have access to communication infrastructures connected to the world with a speed sufficient for active interaction;
- it is necessary to create portable educational tools conforming to various cognitive styles and different cultures;
- it is necessary to have human resources capable of implementing a study course and to lend it a technological and informative form and to train teachers for such course, to develop a virtual community. So far such fundamental assessments are only rare in the market;
- it is necessary to remove the territorial framework of institutions and develop a new management system *focused on the mobility of the content of knowledge rather* than of the students;
- it is necessary to develop a new policy and new systems for quality control and fixation of the results attained;
- it is necessary to resolve the language problems in order to avoid the Babylon Tower syndrome or its opposite — «the imperialism of a single linguistic monopoly».

It is *necessary, necessary, necessary...* there are too many requirements for a single community to tackle these problems alone. At the time when the economy is becoming global, it is necessary to make the very education global. The avenues of informatics are calling for that.

3. Global solutions

The present meeting is an interesting form of entry into the epoch of increasing cooperation in education. We should be thankful to the new information and communication technologies for making us act. Here and everywhere we shall have to:

- collect our local experience to get ready to the great challenges of 1996–2000;
- to agree that although the time of these solutions is today it is impossible to do everything within a day, that each modest step in this direction can improve the global situation;
- to try to determine a minimum of common values so that to take advantage of the phenomenon of information main avenues; to think of the legalization of the rights and liabilities of the «surfers»;
- to make an inventory of our educational data bases and our technological means to develop an exchange market instead of relying on an autarchic development;
- to attract the attention of financial circles and industrial enterprises to join efforts in providing respective *infrastructures,* equipment, teaching *programs,* management software, and most importantly study programs. You know that a multimedia course may cost from \$100 to 400000;
- promote the development of our education institutions so that they would provide scientific standards to the study courses. This is all the more important that our "neurone-*student" is quite independent;*
- finally, and most importantly, we must train teachers in case we want to have the slightest chance for the creation of a future - the new teachers will have to develop new institutions, new educational approaches and new systems.

The final piece of advice that I would like to give to those *for whom the system to be created is new* is to rely on those who already have the experience of virtualization, i.e. specialists in distance education.

CONCLUSION

The future is inseparable from the present and beautiful. Teaching is not the only requirement to be met in our changing world, but it is one of the most important to it.

If we are to gain from the new information and communication technologies, if we are to create good conditions for the birth of a Neurone - Student, if we need migration more than revolution, we should go into all this together and immediately.

Our means are limited everywhere, and, hence, we should think over our objectives well enough — it is better to invest in neurons than in neutrons.

NB. This text could be well illustrated by the supplemented documents obtained in the LICEF Center of the Teleuniversity. It describes the structure and the method of the existence of some virtual campus using new communication technologies.

EVALUATION OF TECHNOLOGY-BASED LEARNING: A SOCIAL SCIENCE APPROACH TO QUALITY ASSURANCE IN EDUCATION

Peter Baumgartner
INSTITUTE FOR INTERDISCIPLINARY RESEARCH AND FURTHER EDUCATION IFF
OF THE UNIVERSITIES OF INNSBRUCK, KLAGENFURT AND VIENNA (AUSTRIA)
Sabine Payr
AUSTRIAN ACADEMIC SOFTWARE INITIATIVE, UNIVERSITY OF KLAGENFURT

ABSTRACT

Some problems of evaluation methods that are commonly used in laic attempt to assure file quality of interactive educational media are outlined. The authors present their heuristic model of the learning process as the basis for an altemative approach. It has the advantage of bringing the social aim and situation of the learning process into focus. This model leads to a qualitative approach to software evaluate in which also helps to define appropriate and creative settings for the use of the software.

1. PROBLEMS OF EDUCATIONAL SOFTWARE EVALUATION

The problem of quality in interactive educational media has accompanied the field since its beginnings. Numerous researchers tried to define criteria of software quality and to compile catalogues from them (see [Doll, 1987], [Thome, 1989], among others). The idea was to translate these catalogues into checklists that could be of practical use for teachers and trainers in judging educational media.

Checklists have the advantage of being cheap and simple to use: no software users (= learners) are needed. But this is also their disadvantage: they cannot make predictions on the context, that is, the specific target group, learning goals, situations etc., in which the software can be more or less usable. Whale they are left to check are those aspects that can be tested and judged without context. These are, however, mostly those questions that can be applied to any kind of software, i.e. whether it is robust, error-free, well-designed, well documented, easy to learn and user-friendly. The specific character of educational media has to remain outside this method.

Empirical methods of evaluation, on the other hand, are costly and time-consuming. They are applied to only a few selected cases of software (often those program developed by the researchers themselves). One well-known method is based on the comparison of groups of learners. One group works with media support, while the reference group - which has to be comparable in age and gender distribution, prior knowledge etc. - works without software support - with books, classroom teaching etc. The comparison (most of the time by standard tests) of bolt groups is supposed to reveal the difference that results from the use of interactive media - be it positive or negative.

For all its complexity, this method has its pitfalls, too. What can be tested objectively is the memory of the contents learned. However, this amounts to an implicit reduction of learning to the mere reproduction of facts. Furthermore, test groups would be. strictly speaking, only really comparable if both traditional and technology supported teaching were completely identical in contents, goals and methods. But if new media are used in this way, they rightly provoke the question what. in these circumstances, is "new" in them.

The problem with both methods is that they reduce the learning process to a number of individual factors: lists of criteria consider the software without the learners, and comparative studies, while considering the learners, treat them as isolated receptacles of knowledge. Learning with software is, however, a social process in at least two ways' first, it takes place in a certain social situation (in the classroom, at work, at home) and is motivated by it. Secondly, any relevant learning process has as its goal the ability to cope with the social situation (professional or everyday tasks, etc.). The evaluation of interactive media then has to satisfy three conditions:

1. It has to take into account the social situation in which the media are used, and must not be limited to the media themselves.
2. It has to take into account the goal of dealing with complex social situations and must not limit itself to the isolated individual learner.
3. It must take into account the specific forms of interaction between the learner and society. These interactions range from the passive reception of static knowledge to the active design of complex, dynamic situations that characterizes the "expert".

These requirements eliminate evaluation methods that can only pick out single factors. At the same time, they make an "objective" discussion of media quality difficult. In what follows, we will first outline a heuristic learning model that can be used to define and to design learning situations on the basis of these three conditions. We will then try to propose an evaluation procedure where the concept of absolute quality is replaced by relative values. These values are defined and determined in discourse - with the software, with the situation, and with the scientific community.

2. A MODEL OF THE LEARNING PROCESS

The model that we propose is inspired by the work of Dreyfus and Dreyfus [Dreyfus and Dreyfus, 1987] who studied the learning process from novice to expert:

1. A novice who does not know anything of the subject he/she is approaching has to start with faking in the facts and rules of it. The application of them to the novice's practice or exercise of the field has to be automatic: the novice cannot decide on which rules to apply and learns them as context-free. Practice is thus limited to imitation, to exercise.
2. The beginner can start to learn the context of the rules, i.e. hat there are different rules to apply in different cases. The practice becomes more varied and more adapted to individual cases, but it is still impossible to act autonomously in the field.
3. At the third stage, the competent person grasps all

the relevant rules and facts of the field and is, for the first time, able to bring his/her own judgment to each case. This is the stage of learning that is often characterized by the lam "problem solving": the conscious and often laborious decision-making process based on the vast repertoire of facts and rules available to the learner.

4. Contrary to most learning theories, this approach, however, does not stop here and does not consider competence to be the final goal of learning. The four stage is called fluency and is characterized by the progress of the learner from the step by step analysis and solving of the situation to the holistic perception of the gestalt of the situation. Just like the situation, its solution also starts to present itself as a holistic pattern or gestalt together with the problem.
5. This ability of gestalt perception is brought to perfection by the expert, the final stage in the learning process. An expert identifies him/herself with the complex real-life situation in which he/she is bound to act. The "art" of the expert consists not in solving problems, but in constructing them out of the amorphous complexity of life. This act of creating the problem already contains its solution.

Most theories of learning stop - as we mentioned above - at the level of competence. Traditional Artificial Intelligence research with its focus on the representation of facts and rules and on problem solving [Baumgartner and Payr 1995 a] I has no small part in this narrowing of our perspective on learning. Practitioners and those who are concerned with their education, like Donald Schoen ([Schoen, 1983]; [Schoen, 1987]) have never been satisfied with this view. Schoen's concept of the "practitioner", for example, shows close similarity to the "expert" characterized above, and his writings about the education of practitioners that have inspired so many educationalists offer an account not only of what it means to be a practitioner, but also of what it could mean to "teach" them.

The problem that we saw was the gap between the view of beginners through to competent learners and the view of experts-to-be: There did not seem to be a hint of how learners pass from one level to the other, nor a unified picture of the strategies required for educating experts or practitioners. Out of this need, we developed the heuristic cube model [Fig. 1] that combines the (meta)contents of learning with the goals of the learner and the learning strategies (see [Baumgartner, 1991], [Baumgartner, 1992], [Baumgartner, 1993], [Baumgartner, 1995], [Baumgartner and Payr 1994], [Baumgartner and Payr, 1995]).

Learning Contents

From left to right, the cube diagram shows learning contents on the level, i.e. not the "subject", but the task of the learner in a certain stage and situation. This dimension offers a fine-grained differentiation of the coarse subject description fig. "equations with two variables"). For example: Should the learners be able to solve the equations given a certain method, should they also be able to choose the adequate method, or should they even be able to extract the equations from an observation or a verbal description? In the first case, the contents of the learning process are context-free rules (like rules for transformation of equations). In the second case, they learn context-sensitive rules, i.e. they have to decide which rules are Loa be applied in what case. The third level (problem solving) deals with solving given systems of equations. On the more advanced levels, the learners first will have to construct the problem themselves out of a complex, real-life situation, before solving it.

Goals of Learning

From bottom to top, the cube represents goals of learning in their order of complexity. This dimension characterizes the types and possibilities of interaction between the learners and the "world" (society, nature). It is based on the experience that novices cannot successfully deduce a solvable problem from a complex real-life situation.

This approach to goals of learning can easily be misunderstood as the reincarnation of traditional, hierarchic notions of learning, where novices had to progress slowly and painfully from rote learning of facts to mindless drill in order to finally be found "worthy" of more complex tasks. This is certainly not what we mean here: rather, this dimension reflects the common experience of learners in which they spontaneously choose those strategies of interaction with the subject that protect them from an overload of complexity. A novice of the language in a foreign country (= complex real-life situation) limits herself, in a first step, to grasping isolated words or idioms in the flow of speech of the natives. Only later will she be able to perceive and analyze longer parts of speech.

Teaching Strategies

From the front to the rear, the cube model shows three different teaching strategies. This dimension attempts to outline the role of the teacher, but also that of the educational media: Are they "teachers" (= explaining, demonstrating), "tutors" (= observing, correcting) or "coaches" (= accompanying, participating)?

Learning Goals and Educational Media

Beside the goals of learning, we put a certain type of educational software. This typology is quite traditional in itself, but, integrated into the general model of learning, it is a starting point for classifying software according to the types of educational interaction it allows, and not only according to design criteria, as is often done. This typology of educational media is done here for only one dimension of the "cube", but could be done equally well for the others. Doublessly, there is an affinity between a certain goal, certain contents and a certain educational strategy. For example, we cannot easily imagine how a learner can master complex situations (contents) without acting him/herself (goal) in a situation where the role of the teacher is that of a participating coach (strategy). But what we want to underline by listing all the possible varieties that can lead the learner from novice to expert is that each sensible combination can be justified in a certain learning situation. Contrary to researchers and developers who are mainly concerned with "interesting" cases of educational media and therefore prefer complex media (simulation, games, microworlds) to seemingly "old" and primitive media (tutorials, practice, presentation), we try to express, in this model, that each type and use of media can be justified and adequate, provided that their use is adapted to the situation - the current goals and contents and the appropriate teaching strategy.

It is therefore also important not to lose sight of the "final" goal of the learner, that is, to become an expert or at least a fluent practitioner in the field. This holistic view of the learning process helps to avoid the risk of a narrow and biased view of learning that is often to be seen, especially in the field of educational technology where the (restricted) potential of media often prompts an equally restricted view of learning.

3. EVALUATING BY GENERATING QUESTIONS

The relevance of this model for the evaluation of educational media lies in the support it gives to the teacher or evaluator in defining the learning situation from the viewpoint of the level that the learners have already reached. By applying it to classes of educational software, it also provides a first orientation not only on the type of media to use, but also on the type of use that could or should be made of this software: most modern educational software packages are complex enough to allow different types of use, e.g. as a pre-defined problem to solve or as an open scenario more or less restricted by pre-set parameters.

To pass from this static analysis of given situations and software functionality's toward a more dynamic approach to evaluation and didactic integration, we suggest a procedure in the form of so-called "generative" questions, as they are used in qualitative social research methods like "grounded theory" ([Glaser and Strauss, 1967], [Strauss, 1987]). These are questions that open up the problem space, draw attention to the problematic points and make solutions comparable. The "generated" concepts can be compared to the criteria that are used in check-lists. But. instead of being pre-defined, these criteria are developed in the context of the given means (media) and ends of the learning situation.

As generative questions address the specific situation, they are not fully predictable. We will try here to define five families of such potential questions. This presentation can neither be complete nor equally relevant for each case:

1. Questions on the relation between different levels of complexity, e.g.: How does the way in which rules are learned prepare the learner for the task of problem solving?
2. Questions concerning one level of complexity: How is complexity increased inside orfe level? How can complexity be reduced?
3. Questions on (implicit) meta-strategies; How does the software support the acquisition of strategies to control the situation? How does the software help the learner to develop learning strategies (like diagnosis, planning, observation etc.)?
4. Questions concerning teaching strategies: Which methods are used to support the construction of mental models, the learner's on activities, or her growing involvement and responsibility?
5. Questions on the social situation: How' is the social context integrated? How does the software prepare the step from virtual to real world? Are there slots for social activities, teacher intervention, and integration of other media?

The aim of the generative questions is to uncover the didactic strategies that underlie the educational medium. In this sense, they are instruments of evaluation or of comparison of different media. At the same time, however, these questions reveal what the medium cannot bring to the learning situation and whit must be looked for elsewhere. Educational media, however sophisticated, play only a small part in the complex learning process. The main part - be it the transition to real-life complexity, be it the background of facts and rules - is left to either to the learner or to the designer of the learning process to provide. In this sense, these questions can help them both to put educational media into perspective and to find in them the clues to create a learning situation that is oriented toward the overall goal of educating experts.

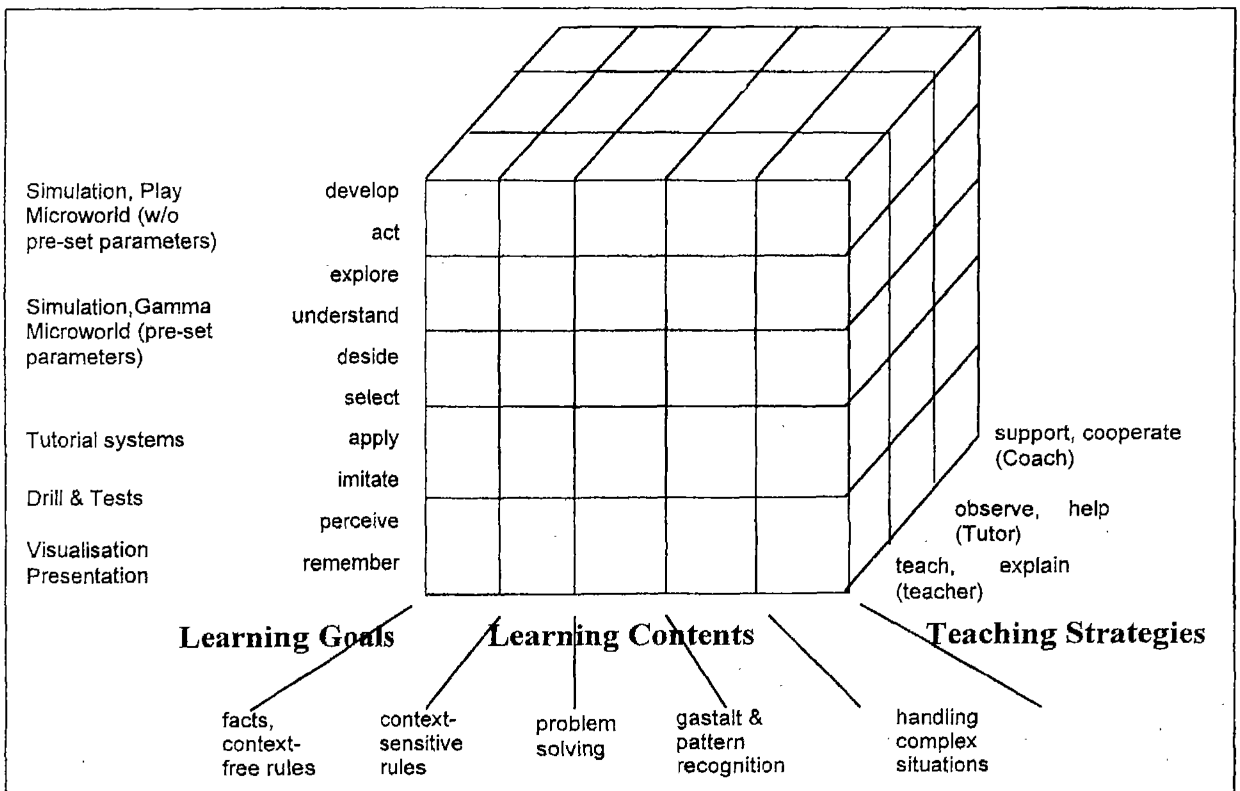

Figure 1. The cube model – a heuristics for defining educatuional (software) situations

Discussion

INFORMATICS IN SCHOOL OVER LAST TEN YEARS

V. A. Bolotov

FIRST DEPUTY MINISTER, MINISTRY OF EDUCATION OF THE RUSSIAN FEDERATION

The intensive development of computer technology started in fifties of the current centenary has basically effected on all spheres of science, political and social-economic life of society. Powerful computers revealed a capacity not only for accumulating and processing information. They also aided in creating communication facilities which made the information accessible at any point on the globe. As a result the modern society has been assigned a metaphorical title of "the information society".

And though informatization history is lasting not for centuries but years, in contrast to mathematics or philosophy, the impressive success of informatization has attracted a great interest of the society. The first computers were constructed about fifty years ago (United States, 1944 - 46). This anniversary is supposed be celebrated within the II International Congress UNESCO that will take place in Moscow. As for wide computer using in Russian schools it has begun since 1985 - 86 e.g. ten years ago.

Since the moment of first computers appearance the educational tasks were defined as follows:

- Preparation of specialists for qualified operating with the computers (professional learning).
- Training of the population for living and working and living under new conditions (general education).
- Using of computers and information technologies capacities for the sake of higher learning efficiency (the development of the educational system itself).

The wide range educational system informatization in Russia started when a new discipline called "Basic Informatics and Computer science" had been introduced into the school program. (At the same time the first computers started delivering to educational structures).

The first steps of educational system informatization in Russia were initiated by the prominent scientists - academicians A. Ershov, Ye. Velikhov, N. Krasovsky, V. Melnikov, who created the concept of educational system informatization in Russia. Besides among these scientists there were the leaders of the technology division - F. Peregudov, V. Afanasiev, M. Leontieva, A. Uvarov. The efforts of these people pushed the process educational system informatization in Russia and to determine most directions of the process in the long run.

The educational reform of 1991 is aimed at the principal transformation of the whole educational system in Russia. If in 1984 the informatization was one of the reform goals, now the reform itself cannot be put forward without informatization.

Regional and municipal accents on the education, the independence increase of educational structures, the new possibilities for choice - all these factors multiplied the number of information users which has included the pupils and his parents on one side and high state authorities on the other side.

New demands concerning operative and direct access to the information resources have also grown. It is related both to the information which is necessary for governing educational system in democratic society and at the same time to "learning" information which is needed for provision of high-quality education for all Russia citizens, independently of place their living.

For the sake of solving this problem Program of education informatization has started in 1994. The program was aimed at complex development of the informatization and meant the agreed cooperation of federal, regional and local level educational structures. In this process the tasks settled within each level are not duplicated but correspond to their competence.

Federal level of the Program includes : elaboration of federal standards in the field of the education informatization, creating a normative basis for development of educational informatization; the methodical provision of federal component for the informatics learning course; supporting for promising directions of educational informatization, providing basic conditions for creation of the unified educational and information space in Russian Federation.

In relation to the regional level the Program offers a complex approach to the creating of the informatization regional programs, a circle of first-priority problems to be solved is marked, the consequence of actions is denoted; a list of structures which could realize the regional programs is recommended, interaction ways of these and analogical structures are indicated.

Among the most important educational informatization programs there are following positions: elaboration of regional standards and other normative documents, providing educational informatization system implementation in the region; learning and methodical provision of educational informatization system regional component; educational structures equipment (with exception for those are related to the federal level) with computers and with other informatization means with computers and with other informatization means, maintaining computer's equipment; training programs for lecturers staff based on the regional Institutes for Teacher Development and Informatization centres; creating regional networks; accumulation of pedagogical information. By now the regional educational informatization programs in more than 50 subjects of Russian Federation.

In 1995 an idea of interregional cooperation offered by the above mentioned program was pushed forward. Thanks to the active attitude of Primorsky Area People Education Department, the "Agrement on Coordination of Ministry of Education of the Russian Federation and East Siberia and Far East regions Joint Activity in the education informafization field". This document assumes the creating of informarization programs for education in all regions, signed the agreeement, coordination of the activity, partnership inthe course of different progects implementation. The Agreement is supposed to be a base for analogical agreements between the Ministry and other Russian Federation regions.

The equipment of schools is realized mainly within the framework of regional informatization programms.

In Russian Federation there are about 35000 schools. Among them there are complete secondary schools, which are equipped with the computers first of all.

At present most of institutions of general secondary education and institutions of primery vocational education are provided with computer science cabinets. Annually the computer fleet is filled up with about twenty thousands of computers.

It should be marked that for the last years only up-to-date computer equipment has been delivered (mostly it was *IBM*-compatible technique). *Mac*-type computers have been installed in some (approximately 500) schools as well.

In spite of the fact, that the most popular way of using computer technique is still computer classes, in some secondary schools the transition to creating unified information space inside schools starts being realised. The process of school "media-libraries" creating is taking place in some schools.

In pedagogical institutes and Institutes for Teacher Development not only teachers but engineers, working in the branch, take their training courses. Special standarts of pedagogical education are directed at the preparation both of informatization teachers and teachers of traditional school disciplines (whose second qualification is informatics teaching).

At present the learning structure elaborated within the Program is fully provided with educational supplies and leaning softwares. Regretfully a shortage of methodical supplies does not allow varying the process of learning.

The work on creating telecommunication network is one of the most significant directions. In some areas of Russia special network centres were created. Centres in Barnaul and Perm should be specially marked. Practically all the pedagogical universities started using the networks.

An "Inform-education" network has been widespread, which is based upon the transmission of information along TV channels. This network counts up to 100 users in 40 regions of Russia. Since1995 all the documents of the Ministry of Education of the Russian Federation have been transmitted through this network.

Since 1994 e-mail is used for the performance of all-Russian olimpiads.

The data banks of different content have been created. For example, the pedagogical data bank, elaborated in Institute for Teacher Development was acquired in 49 regions of Russian Federation. Practically in all regions taking part in the Informatization Program there were realized databases including statistics on methodical, staff, technological state within educational structures.

Informatization and international cooperation are closely related. The information infrastructure of Russian Federation is a part of world one and joining of any school to educational telecommunication networks in Russia is a chance to become a part of world education space.

Practically all international projects in the education area have something to do with informatization.

The realization of joint projects by schools-partners from different countries is becoming more popular. The e-mail information exchange between them has involved more than 2 000 Russian schools. Besides Russian pupils are rather successful in the international informatics olimpiads.

Nevertheless the number of international projects on "Informatics and Education" is not great. Among these projects the competition of school manuals supervised by International Fondation "Cultural Initiative" (Soros Fondation) is worth mentioning. In the course of competition 150 manuals on informatics and software have been considered (half of the works were awarded with grants and is being prepared for publishing) .

We hope that in the nearest future number of international projects on informatics will considerably grows. The UNESCO Congress in Moscow is a contributionary factor for this process. Moreover it looks promising that before the Congress a number of projects, offered by Russian Federation has been supported by UNESCO and is to be carried out with the participation of this respected organization.

IT SUPPORTED CURRICULUM CONTROL IN HUNGARY

Káldi Tamás
PROJECT MANAGER (HUNGARY)

Kádár-Fülöp Judit
MENTOR LTD (HUNGARY)

SUMMARY

There is a convergence in the development of curriculum control in different countries. Countries previously dictating curricula to their schools relax their strict central curriculum control whereas countries where there was no national curriculum control before introduce national curricula. For more effective communication about the goals, objectives and contents of teaming between parties interested in education, a new multilevel curriculum control system, as well as a standard curriculum model is proposed.

The proposed curriculum control system recognizes the distinction between long term and short term, central and local planning. It recognizes the role of the national government, school authority, school, teacher and even the student in influencing the curriculum.

The Profit curriculum is a hypertext database, a project plan and a curriculum document. It is based on the hierarchical structure of long term and short term study units. By this method core curricula, model curricula and local curricula can be described within the same framework allowing referencing between different levels of curriculum control. The refinement and adoption of the curriculum framework as well as the computer aided curriculum development system is proposed to be one of the priority areas of regional and global collaboration to harmonize and improve the different national education systems.

INTRODUCTION

Although, curriculum is a fuzzy concept, curricula exist in abundance. Curricula are developed and implemented on the on the personal level (by parents and students), on the class level (by the teacher), on the school and on the local educational authority level as well as on the national level. We expect that some parts of the curricula might soon be developed on the intemational level. It is essential that curricula are harmonized across subjects, school types and school systems to make a maximum use of teaching and teaming time to the benefit of the student and of society. To be able to effectively harmonize curricula, we need a common curriculum framework and, preferably, a tool supporting and enforcing its application. The Profile curriculum framework and software is an attempt at providing these.

CURRENT TRENDS IN CURRICULUM CONTROL

European integration trends as well as the common concern for the quality and equivalence of education have led to convergence between the various models of content and quality control. In recent years national curricula have been issued in countries where none before (like England or the Netherlands). There is an effort to develop methodology and technology for standardizing examinations in countries where the curriculum was the means of national quality control rather than a state examination system (e.g. in Sweden).

Finally, there is a clear trend of internationalization both of curricula and of examination systems. An example of the former is the Threshold Level Foreign language curriculum frame, which guides curriculum development and textbook writing all over Europe today. An example of the latter is the International Baccalaureate, the international recognition of certain language examinations, and the informal and formal co-operation between agencies commissioned to provide national secondary examinations (like the Cambridge Examination Syndicate and Cito, or Cito and National Institute of Public Education in Hungary).

On the other hand, tendencies for standardization and internationalization are balanced by a stronger claim for local control in the content of education. Parents' leagues, associations for the freedom of education, regional authorities, and the schools themselves insist that those concerned must have a right to choose an education that is suitable to them.

THE TRANSITION IN HUNGARY

The development of a new system of content and quality control was started already in 1988. Work on a new type of national curriculum started in 1988 by a group of educational researchers, curriculum experts and teachers. This first attempt resulted in the "Green Book" (Báthory et al., 1992) containing attainment targets and desired attainment levels at two key stages of education (Grade 6 and 10). The Green Book raised controversial political feelings, mainly because the authors decided not to touch the issues of values in education. It was felt that the fundamental change in the political setup and in the view of education would require a declaration of basic values, principles and goals of education to guide curriculum planners. It was argued that on the national level only Curriculum Guidelines are needed stating general principles of education and that frame curricula and/or a variety of elaborated curricula for the various school types should specify the content and objectives of teaching. The political debate behind this argument was how far the former uniformity of the Grades 5-8 curriculum should give way to the separatist efforts of new secondary school types like the 8-year *gimnázium* or the 6-year gimnázium. The dangers of a growing selectivity of the system are certainly not to be underestimated but, and that was pointed out in the debate too, selectivity of the system covertly exists as it was shown in a series of national and international achievement studies. The debate was — at least temporarily — cooled down by a comprising curriculum control model laid out in the new Act on Public Education. The Act establishes the legal framework of curriculum control. The government approved the National Curriculum at the end of 1995. As a consequence all schools have to adapt or develop their local curricula confirming to the National Curriculum until 1998.

The allocation of responsibilities for planning education is shown in Table 1. On the national level general principles of education, content areas, and attainment targets are specified. Attempt is being made to define desired attainment levels at key stages of education (Grades 4, 6, 8, 10). For the various secondary level school types model curricula are being developed, which answer the specific needs of different groups of students. Model curricula are being developed for secondary schools with varying vocational lines, for academic secondary schools of various length, for special education purposes, etc. The attainment levels at key stages will serve harmonizing purposes to keep writers of model curricula from too ambitious plans. Contrary to the detailed curricula of the 1980-ies, model curricula will have to leave room for local (school level) planning and they will also have to keep the system flexible allowing children to change school type without great difficulty at least until the age of 14. Model curricula are licensed by the Ministry of Education according to the Act on Public Education. On the third level, schools are required to have their own detailed curricula (programmes of studies), which they can either develop themselves on the basis of a model curriculum or which they can jointly develop with or take from other schools.

A national examination system with elements of standardization will also have to be developed according to the Act on Public Education. Thus the state is responsible for harmonizing curricula between school types on the secondary level and for quality control of public education via the examination system. Local authorities are responsible for controlling school level curriculum development. The schools are responsible for planning their own work and implementing their plans.

Since planning on the school level was nor part of the duties of the teaching staff during the past fifty years, it is main concern how schools will is their own planning. The problem is so much the greater that state organized curriculum development work also followed a trend of subject matter chauvinism in the last decades and the expertise in general planning of education has become meagre. The result was an overloaded curriculum and verbalism at the expense of experiential and activity based learning. Compartmentalized teacher training enhanced (and still is enhancing) the unfavourable effects of competition between subjects and a lack of co-operation between teachers. To change this trend is the major task of educational policy and state supported development in the coming years.

Table 1

Allocation of Responsibilities Concerning Content and Quality Control in the 1993 Education Act in Hungary

Task	National Level	Local (School Authority) Level	School Level
Content Planning (curriculum development and curriculum control)	National Curriculum (guidelines for planners and attainment targets at key stages (Grades 4, 6, 8, 10). Quality control of model curricula for basic school types. Methodological support to local development Projects for translating new content into curricula	Reviewing and authorizing school level curricula (pedagogical program). Development of model curricula (particularly in the case of Church maintained school systems)	Development or selection and adoption of the school curriculum (teaching program). Selection of textbooks from the textbook market
Implementation	National Education Institute, Teachers training, Postgraduate training, "training of trainers"	County Pedagogical Institutes, Teacher adviser network, support of local innovation, curriculum information	Teaching, Innovation
Evaluation	Development and maintenance of the national examination system. National assessment of educational achievement in key subjects. Research on the conditions of learning (input-output relationships). Educational statistics	Evaluation of the local school system from the point of view of the local labour market. Analysis and evaluation of publicly available data concerning the local school system. Evaluation of cost-effectiveness of education in the local area	Evaluation of pupils' progress. Certification. Evaluation of the work of the teaching staff. (Self-assessment). Evaluation of feedback from students and examination results about the school curriculum (pedagogical program)

THE PROFIL COMPUTER AIDED CURRICULUM DEVELOPMENT SYSTEM AND THE PROFIL SOFTWARE TOOL

The threat of a curriculum chaos as a reaction to the curriculum dictature inspired curriculum theorists and researchers in informatics to find new technologies of keeping change under control. From 1990 onwards several development projects were initiated by specialists of the Hungarian software firm Mentor Informatika, school managers, and curriculum specialists. The projects were co-financed by the Ministry of Labour and the Ministry of Culture and Education to develop a standardized system of curriculum description and to develop the framework of a curriculum database. The idea was that standardization of the *form of curriculum description* is a necessary condition of modular planning. Modular planning, on the other hand, is the only way of keeping planning costs reasonable and still meet the varied needs in education. It was also viewed that standardization of curriculum design would also facilitate communication and co-operation between subjects specialists, curriculum theorists and teachers in the course of planning. By analogy, the standard format of curriculum description was meant to serve the same purpose as technical drawing in designing a building or a machine. A third — long term — goal behind the projects was to lay the foundation for a future curriculum database to facilitate the dissemination of curriculum information and the results of curriculum innovation by electronic means. The requirement that schools have their own curriculum document emphasizes the need of standardizing curriculum format and of setting up a curriculum database which can be used as a resource center for schools planning their own curricula. The result of the development work is the Profil Computer Aided Curriculum System and the Profil Software — a versatile and easy to use tool for recording, browsing, analysing, editing, reviewing, and modifying curricula. Co-operating with Ms Word, Ms Project and Ms Excel the Profil software can produce charts and tables mapping the learning modules, creating projects plans, timetables, showing pre-conditional relationships and cross-referencing possibilities between study units in the curriculum. In a pilot project carried out in 1993 it was shown that any existing curriculum which has a sufficient professional skills can use the software even if ho or she has not had any practice in using computers.

The Profit Curriculum Framework

What is if?	Profil describes the curriculum as a structured plan of education and instruction. On any level, a curriculum can be characterized by the aims, objectives, entry requirements, content, assessment methods, and the resources of teaching (i.e. teacher qualifications, specific learning environment, textbooks, etc.).		
Curriculum Modules	Structured curricula are described as interrelated networks of curriculum modules within and between levels of curriculum control. In the Profil framework the modules are classified in three major categories and eleven types:		
	Study modules	Assessment modules	Other units
	curricula (study schemes) grades (levels) subjects (study areas) topics (themes) subtopics (study units) lessons (classes)	exams and tests	books equipment partners: schools, institutes, publishers, etc. trades

The necessary equipment, textbooks and other resources can be specified for study modules and assessment modules. A register of schools, job families and trades completes the database.

The Standard Structure of Study and Assessment Modules	*The study and assessment categories comprise seven distinct module types. These module types describe the curricula on different levels of abstraction. The module types have a common frame of description. They are all described by their main attributes as follows*	
	Attribute	Description
	Aims and Goals	The rationale of the module's existence, the reason why the student wants to cover the study module or why the teacher thinks the module is important for the student
	Objectives	The expected learning outcomes, i.e. the knowledge and skills the student can hope to acquire as a consequence of the education and training described under the attribute *contents.* Objectives refer to envisaged performance as far as it can be predicted in advance. Normally it specifies what under what circumstances to what extent the student might be able to perform after having completed the study module
	Prerequisites	The knowledge, attitudes, and skills the student is assumed to possess before entering the current module. The modules of a well designed curriculum usually build on one another. The entry conditions can be described as free text, or by pointing at exams, tests, or other study modules to be covered before the module
	Content	The material to be covered, the activities to be carried out, the task to be performed in order to reach the target formulated under *objectives.* The content can be structured according to the specific discipline or according to the activities and tasks to be performed. The different structures can be cross-referenced using textual pointers. Content can be described as free text or by pointing at lower level (more detailed) study modules as parts of the module in question (e.g. topics of a subject). The description of content can specify how the module contributes to achieving the more general aims of education (such as creativity or cooperativity) or specific attainment targets (such as reading or writing skills, etc.)
	Assessment and Evaluation	Description of the procedure designed to assess how far the objectives of the module have been reached. Assessment methods, criteria, examples of performance levels can be described as free text, or reference can be made to examination modules within the Profil database
	Resources	The resources needed to complete the study module. Data such as minimum and maximum group size, number of teachers required, classrooms, labs, equipment, textbooks are entered here. Resource data help the school administration to plan teacher and room allocations as well as to order textbooks, etc.
	Identification	Study modules are labelled with the name, version, character, structure and study time of the module. Identification data help the school administration to plan the overall study scheme of the student groups with various needs and study background

THE PROFIL SOFTWARE

The Functions of the Profil Sotfware

- entering the curriculum into the computer, storing it in a database, accessing the database (database view);
- analysis of curricula (project and cross reference view);
- curriculum publication (publication).

Database *view.* By help of the Profil software curricula can be entered into a computer, stored in a database and browsed. Moving around in the database is as easy as searching in the ERIC database. Navigation buttons help the reader to move between levels in the hierarchy, within the same level of the unit hierarchy, and between attributes within a unit. When moving between units, the selected attribute remains the same. Thus, if one selects the "objectives" attribute, it is possible to move around (up and down or between) "sister units" under the same "parent units" to compare objectives.

Project and cross reference view. The analysis of curricula is based on database extracts generated by the Profil software. Analysis of unit structure and interconnections can reveal inconsistencies in planning (like lack of referencing insufficient coordination between subjects). Analysis of topic coordination may give ideas of how information in one subject can be immediately applied in another subject or how activities in one subject can serve objectives of another.

Publication. The curriculum or part of it can be arranged into a standard format curriculum document. Database extracts generated by the Profil software are automatically fed to the word processing program (Ms Word) to produce a standard format printed curriculum document.

NEW INFORMATION TECHNOLOGY AND TEACHERS

Qian Kunming
DEPUTY DIRECTOR THE DISTANCE EDUCATION INSTITUTE
RADIO & TV UNIVERSITY OF CHINA

Li Guobin
ENGINEER THE DISTANCE EDUCATION INSTITUTE
RADIO & TV UNIVERSITY OF CHINA

The rapid development of information and communication are changing our society, life, as well as education. "The information society" characterized by "information highway" is coming soon. The traditional education model and the system based on teacher-center become obviously unsuitable for such a change. This is a problem to which all of us who are working in the field of education must face.

In this report, we would like to say something about teachers and new information technologies (NIT) in reference with the practice in China.

TEACHERS TRAINING USING NIT

Background

China is a developing country and has a very vast population. According to statistics, in the end of '80th. there were about 5.5 million of primary and 2.4 million of junior middle school teachers. Among them about 38.2 % of teachers were unqualified (Table 1). About 2.7 million 6-12 years old children were unable to go to school in the same period and about 1.4 million qualified teachers will retired during the next ten years. In a word, there were about 5 million of qualified primary and secondary school teachers being lacking.

Meanwhile, there were 262 higher level teacher colleges, 1056 secondary level teacher training schools, by means of such traditional way only about 0.2 million primary school teachers and 0.13 junior middle school teachers could be available each year. In addition, the in-service teachers could not be trained stopping their work. It is obviously far from satisfactory (See Table 2).

The practice of Radio & TV University of China (RTVU), which established in 1979, showed it's unquestionable success in its early stage. About 1.5 million college graduates poured out in 8 years only, which is about 1/2 of the graduates from about 2000 other adult colleges in China.

Inspired by such an unprecedented success in the history of education, the Chinese government decided to use NIT to train teachers to carry out the nine-year Compulsory Education.

Satellite TV Teacher Training in China

China TV Teachers College (CTVTC) was found in July 1987, for speeding up the step of primary and secondary school teachers training.

CTVTC is responsible for:

- Providing the in-service training for the primary and junior middle school teachers and upgrading their education level.

Table 1

Numbers of Schools, Students & Teachers in Schools

	1988		1995	
	Primary Schools	Junior Middle Schools	Primary Schools	Junior Middle Schools
Numbers of Schools	793 261	88 290	668 685	77 742

Numbers of Graduates for School Teachers in 1988

	Higher level Teachers College	*Secondary Level Teacher School*	*Notice*
Numbers of Schools	262	1056	Total: 1318
Normal Course Higher Level	48 913	—	For senior middle school teachers
Short-Cycle Course Higher Level	130 207	—	For junior middle school teachers
Secondary Level	—	203 518	For primary school teachers
Subtotal	179 382	204 574	Total: 382 638

From : Educational Statistics Yearbook of China, 1988

• Providing the continuing education for primary and secondary school teachers.

• Providing the in-service training for schoolmasters and upgrading their managerial level.

CTVTC is in charge of the organization and production of training materials. The registration and teaching management is handled by the local government. The works, such as teaching organization, students' administration, exams, and granting certificate are carried out by the local regular and adult teacher training colleges and schools. The students learn through TV mainly and get the face to face guide from tutors. They will get diplomas if they passed the examination worked out by the China Examination Center.

There is a national network of satellite TV normal education in China. Two sets of educational programs are transmitted through the Chinese communication satellite. Their down-frequencies are 3880 and 3840 MHz. The third special channel (its down-frequency is 3800 MHz) for educational TV program by satellite start working in March 1995. it covered the whole area of China (including HongKong and Taiwan), Japan, Korea, India and other near by regions.

CTVTC provides courses in a wide range of subjects at both higher and secondary levels. Up to now, about 156 subjects, 12000 hours visual teaching programs have been produced. There are totally 16.6 million copies of textbook for 211 courses (see Table 3).

Most of the TV lecturers, who are mainly from regular normal universities and colleges, are famous in China and have a rich experience for teaching. Some foreign professors and excellent teachers from primary and secondary schools were invited to be TV lecturers too.

The Result

CTVTC has offered 360,000 graduated students since its establishment. Meanwhile, about 2 million in-service school teachers and 1.0 million schoolmasters have watched the TV courses of continuing education.

GTVTC checks the quality of TV normal education through exam each year. According to the statistics of 90,000 graduated students in 10 provinces about the course of "Fundamental of Nature Science", 73.1 percent of the students passed the exam, and 22.6 percent of the students scored the excellent marks. About 14,000 students from nine provinces took the exam of "Chinese ancient literature", 84.8 percent passed the exam, and 38,9 percent got the excellent marks. Table 4 shows another example of sample survey, and Table 5 gives the comparison of 1988 and 1995.

The survey of the graduated students indicates that the students have made great progress in specific professional knowledge and teaching ability. Most of the graduates have become the main force in their schools.

The Chinese satellite TV normal education is an open education system, and plays an important role for spreading Nine-Year Compulsory Education. CTVTC, which only has 35 staffs and a small budget, has provided a good training service with the aid of TV and local adult teacher colleges/schools. It shows the NIT

Table 3. Teaching Materials Organized by CTVTC (1987-1995)

	TV Training Programs		Printing Teaching Materials	
	Courses	Hours	Courses	Volumes
Training for Primary School Teachers	16	1 155	16	1.17 Million
Training for Secondary School Teachers	130	>8000	183	13.4 Million
Post training for Primary & Secondary Schoolmasters	10	517	12	2.00 Million
Continuing Education for Secondary School Teachers	—	1450	—	—
Continuing Education for Primary School Teachers	—	572	—	—
Total	156	12000	211	16. 57 Million

From "China Television Teachers College", 1995

Table 5 Breakdown of Full-time School Teachers by Education Attainment

Education Attainment	1988		1995	
	Primary Schools	Junior Middle Schools	Primary Schools	Junior Middle Schools
Completion of Specialized Higher Education	2169953	855 627	4160755	1924362
Completion of Specialized Secondary Education		1435703		650 031
Completion of General Secondary Education & Below	3331347	111412	1 503 302	209 328
Qualified Rate	42. 47 %	35. 61 %	73. 46 %	69. 13 %
Subtotal	5501300	2 402 742	5 664 057	2 783 721
Total	7904042 (38. 27%)		8447778 (72. 03%)	

From "Educational Statistics Yearbook of China", 1988 & 1995 has a powerful activity in education.

THE INFLUENCE ON TEACHERS OF NIT

The alteration of education model

Tracing back to the history of human education, we can see that the earliest educational function was displayed by parents transmitting knowledge by means of speech to the own children in their families. With the development of productive forces and the emerge of written languages and especially the printing technology, the duty of education diverts to specific professional teachers from family, and Education as a sort of occupation stands off from other social activities.

In the 19th century, the developments of postal service career make education spreading outside the campus — so called "correspondence education".

The development of electronics technology in 20th century causes many new educational media and methods (slide projectors, recorders, videos, films, etc.). These new media are widely used in classroom teaching, which raises regular education efficiency greatly, and enriches the content of teaching. Such model is named as "Audio-visual Education" in China.

The even larger changing caused by using electronic media and communication technology provided new methods for correspondence education, and the distance education came into being. Nowadays, distance education is no complement of regular education yet, but an independent education model. Its effect is not only expanding education scale, but also accelerating the changing of education ideas and concepts.

The way of information exchange has been changed by NIT. New education ideas and concepts are reflected through these aspects listed below.

The whole life of humanity is no longer simply divided into two periods (being educated and doing contributions). The concept of lifelong education has been admitted widely. The practice shows that the traditional school can not undertake the task of lifelong education. To fulfil such a need there must be a large education system and the use of modern communication means. This is just where the function of the distance education lies.

The transform from teacher-center to student-center has been accelerated. People are no longer satisfied by getting knowledge from school passively. They hope they can get flexible learning opportunities and can choose the subjects, time schedule and study place according to their own will. The way of "students accepting what the teachers offer" is replaced by "teachers giving what the students want".

The distance education satisfies the demand of society more easily. Various styles of education (diploma education, continue education, professional education, certificate education, post training, preservice and in-service training...) are being formed. International cooperation and exchange of education in a world scale are becoming promoted. Educational resources are shared by more learners, even beyond over the border of countries.

Distance education makes full use of electronic and communication technology (radio, television, computer, microwave, satellite, optical cable, etc.). Technology and education are combined tightly much more than before.

The process of teaching and learning is separated into two relatively independent parts by using new educational media. The production of teaching materials has been vested with some industry features. The role of teachers has been changed too.

Because of the separation of teachers and students, a serious and difficult problem is formed for the distance education — the lack of teaching feedback and moral exchange between teachers and students. In some countries people make a great deal of effort using telephone, fax, optical cable visual communication, etc. But not until the of computer and its network technology (which will be mentioned more in details in the following) greatly developed, the possibility to solve such a problem had ever been foreseen.

The change of the teachers role

In traditional education, the teaching activity of teachers is an individual action basically. Teachers prepare their lectures individually, and give their lectures in classroom face to face with their students. They can adjust the contents and pace of teaching according to the response of students.

In distance education the teaching process of teachers has been put into the teaching media when using the audio visual and computer technologies. Students get the knowledge from the teaching materials mainly. The use of teaching materials is separated from the design and production of them.

In the practice of The Radio & TV University of China (RTVU) we are aware of the above change.

In the beginning of the establishment of RTVU, we only simply moved the teacher's lecture to the TV screens basically with the traditional model so that the advantage of multimedia teaching could not be realized in such a way.

When we tried to improve our teaching materials we found that there was no common language between the teachers who did not understand the educational technology and the program directors who were unfamiliar with teaching. The directors could not make any good educational program without a good program scripts, even if they were skilful at the production. It needs a kind of person who can coordinate with this. So a kind of new teacher so called "Course Coordinator" (CC) was taking place in RTVU.

CC is a key person in the multi-media education. Firstly, he is the organizer of a course group, and has to deal with various departments and people. He must take part in the whole process, from planing to evaluation. Secondly, he is the designer of multi-media teaching materials. He needs to rewrite the lecturers' scripts into the program scripts, which can be used in program production. Obviously, he must understand both teaching and technology and must be good at both organization and management. It is a very high requirement (see Appendix 2).

For training our teachers to fit into the requirements, in 1989 the RTVU cooperated with NHK of Japan producing a set of multi-media training materials called "Audio-Visual Training Package" which is specifically for training teachers and production staffs how to make the visual teaching programs better. This package includes a 450 page textbook and 14 visual programs. With this package, RTVU has organized training programs for CC and technicians and has rotten a good result. The quality of visual teaching programs has been improved obviously now.

One kind of the teachers is lecturers who are in charge of teaching contents. They also have to study more about the rule of distance education and new technologies; otherwise they can not make good lectures in visual programs.

The other are tutors who give the guidance and constancy directly to learners and assist CC with evaluations. Such a function is different from that of the tutor in regular schools too. For the student-centered system, most of students are not studying in classrooms. They have their own schedules and requirements which

Table 6

Influence of Information on Education

	Industry Society	Information Society
Teaching Objects	Registered Student	Anybody
Teaching Target	Ability of Master & Use Knowledge	Ability of Search, Analysis & Use
Study Period	Study Age (6-25)	All Life
Study Place	In Schools	Anywhere, In Home & Office
Study Planning	From Teachers	From Student Partly
Study Process	Synchronous & Orderly	Asynchronous & Orderlies
Relations Between Teacher and Student	Authority & Instructor	Tutor, Guilders & Friend
Relations Among Students	Competitor	Competitor & Friend
Management of Study	Administration & Organization	Service & Organization

tutors have to follow.

In regular and adult universities and schools there are more and more teachers working just like those in RTVU. It is believed that the role of teachers would change more and more in the future too.

Face to Next Century

Distance education separates teachers and students, while the computer being them together with the network.

We are facing a growing flood of data. The digital technology will provide more powerful tools for learning and representation and communication of knowledge. The Internet allows for information to be transferred for the benefit of all levels of education. The learners can accept information resources and study from TV and computer screen in any isolated areas of the world.

Along with the development of information and communication technology characterized by computer a new education model is being formed now.

By the computer multimedia and network, learners could make contact with any person at whatever place, who has a computer connecting with the Internet at any time. They could see each other on their screens and could exchange ideas in conversations in real time. The whole process of study can be saved as a file and can be sent back to the study center by the Internet. It means that teachers can get immediately not only the response, but also the evaluation from learners which would be more objective than that from guestionnaires.

Another difference between new model and distance education is that the computer hypermedia can provide a great range of various interactions means. And yet the educational information organized by such hypermedia as a net structure which could be similar to the form of human brain. Such a function is an unprecedented one.

To differentiate the new forms of education from the distance education, it seems a new terminology is necessary. Considering that people study mainly through computer screens, which do not display the true world, but only images, and all the characters, pictures and sounds are made up of digital information, namely the imitation of the true world only, here I think it is no harm in naming the new model (apparently near by, in fact far away) as "Virtual Education".

In virtual education, the abilities of searching, selecting, indexing, using and evaluating information become more important. More and more learners would study in families through computer and TV. Teachers have to develop such abilities before teaching and have to be fit into the model of individual studying. They must be guides, consultants, and friends of learners.

All of these would accelerate the change of education, which has been done by distance education. This change must include the following aspects at least.

- **Individualization** — study would enter families. More and more people will learn individually. Students would be given a greatest freedom of learning.
- **Socialization** — the scale of learning would be enlarged greatly. The right of being educated regarded as one of human rights would become more and more practicable.
- **Lifespanness** — people would study for their whole live. The continuing education and lifelong education would be an important part of society.
- **Diversity** — virtual education, distance education and conventional education would be complemented each other. Various forms of education (diploma education, continuing education, professional and vocational training, pre-service and in-service training, etc.) and various options of means (video, radio, television, the Internet, etc.) would be working together. People will have more opportunities and more choices of learning.
- **Informatization** — those who own information would own everything. Computer and the Internet would be the main means for getting information. So to master computers would be the basic skill of every person.
- **Modernization** — the combination of education and technology has never been so tightly joined as today. All kinds of signals (text, picture, video, sound movie, etc.) would be put together by the computer multimedia technology. It would make the process of education more vivid and more efficiently.
- **Internationalization** — cooperation in education would be spreading greatly. Through the computer network, education resources would be shared by more and more people in great many fields. Learners, teachers and others could have real-time exchange in a world scale.

Along with these changes, the education in information society would be bound to be greatly different from that in the industry society (see Table 6). I think the followings are necessary for teachers to get ready in the future at least.

- To be suitable to the student-centered education system.
- To make teaching materials using NIT with the idea of the student-center.
- To learn the education technologies and to use them to improve education quality and efficiency.
- To study to be a designer and organizer of production of audio-visual teaching program and computer assistant instruction software.

The rapid development of NIT provides for us a very encouraging future in terms of education. However, the technology, no matter how advanced it might be, can not replaced the human brain. The aims of education are not only to give learners knowledge, but also to teach them how to be a human being. We had better be aware, at the same, of the danger of the lack of direct interpersonal exchange when advanced technologies are used widely for education, as this exchange has been cherished a valuable part of education. Therefore, when using NIT for education, the role of direct moral exchange must be emphasized for education.

APPENDIX I

Some Names of TV Columns for Teacher Continuing Education

1. "Friends of Primary School Teachers"
"One Lesson in One Week"
"Window of Education Reform"
"New Teaching Materials"
"Experiences from Famous Teachers"
"Research and Exploration"
"Solving the Problems"
2. "Friends of Secondary School Teachers"
"Teaching Demonstration"
"Teaching Methods"
"Political and Historical Views"
"New Knowledge of Subject"
"Theory and Research"
"Foreign Language Teaching"
"Basic Skill Training"
3. "Schoolmasters"
"Research of School Management"
"Schoolmasters Learning Law" "Excellent Schoolmasters" "Special School Views"
"Moral Education Garden"

APPENDIX 2

Duties of Course coordinator in RTVU

1. *To take part in the policy and planing of courses.*
2. *To organize the draft of teaching outline and design of multi-media teaching materials.*
3. *To choose lecturer, chief editor of textbook, director of program and to set up course group.*
4. *To rewrite the script of audio-visual teaching programs.*
5. *To assists director completing camera script and program production.*
6. *To organize the examination and revise of teaching materials.*
7. *To organize the training of tutors and evaluation of teaching materials.*

THE TEACHER IN THE CONTEXT OF NATIONAL AND REGIONAL PROSPECTS FOR INFORMATIZATION OF EDUCATION

A.L. Semenov
RECTOR, THE MOSCOW INSTITUTE FOR TEACHER DEVELOPMENT,
VICE-CHAIRMAN, THE MOSCOW COMMITTEE FOR EDUCATION,
HEAD OF THE INFORMATICS AND COMPUTING DEPARTMENT
AT THE INTERNATIONAL UNIVERSITY (RUSSIA)

THE BEGINNING

Large-scale introduction of informatics in Russia's secondary schools began 12 years ago under the ideological leadership and practical management of the late Andrei Ershov. The following years showed that the basic conceptual decisions passed at that time still lie within the mainstream of «school informatics». Take, for instance, the UNESCO-IFIP recommendations disseminated by this Congress.

It was stated at the very beginning that there exist three trends in school informatics: mathematical informatics; the study of information technologies; and the application of information technologies in the teaching of other subjects on the secondary school curriculum.

HISTORY

In the next ten years, mathematical informatics and information technologies were brought together in a single discipline, «Fundamentals of Informatics and Computer Sciences». The application of information technologies in the teaching of other disciplines proved a job for the few enthusiasts.

As the information industry advanced, several generations of computers succeeded each other. But they usually stayed locked up in the «informatics classrooms» equipped with a certain mandatory number of machines and in the closed local networks. Most informatics teachers were former computer programmers who acted out a variety of roles, from a magician easily able to send a letter to your former pupil in Arizona absolutely free of charge or produce an elegant invitation to a school-leaving ball, to sorcerer who, sitting behind steel doors equipped with combination locks, summons ventrilogistic Internet spirits through a window to the other world twinkling with green DOS cablegrams, or bewitches children with computer games or, God forbid, C++ coding. To obtain a computer for their own use (for the sake of prestige and to facilitate the writing of instructions), school principals resorted to a variety of modes of action, including ones punishable under criminal and administrative Law. As a parallel process, Soviet and Russian schools cultivated a set of «technical» subjects and modules which included sewing and cooking for girls and metalworking for boys, technical drawing, practical training at the so-called teaching production centers, etc. Although such subjects may have had their uses, the gap between the methods and substance of teaching, on the one hand, and the life outside the school walls, on the other, was widening.

CHANGES

We are standing on the brink or radical reforms.

The Federal Law «On Education» introduces two «informatics fields» to be covered by secondary school courses in Russia: «Mathematics and Informatics» and «Technology» (among the adjacent fields, «Natural Sciences»). Information technologies are taught within the framework of the latter course, and mathematical informatics - within the former. The constructionist educational paradigm, which in many countries is occupying an expanding place in the serious projects designed to introduce information technologies into secondary education, is becoming a practical philosophy of many Russian teachers of informatics and is influencing other subjects on the secondary school curricula. The most distinguished representative of constructionism in world computer education is, of course, Seymour Papert, a pupil of Piaget and himself head of a major scientific school. Papert is known and respected in Russia, he spends a great deal of time in Moscow and St. Petersburg. One can get an idea of his educational philosophy from L.B. Pereverzev's article in the magazine *Informatika i obrazovanie (Informatics and Education)*, nos. 4-5, 1995. A breakthrough occurred when a group of researchers working in academic, university, and defense science set up the Institute of New Educational Technologies (INET). The Institute, which is headed by E.I. Bulin-Sokolova, a linguist and teacher, enjoys decisive support from the Moscow public education bodies and has already become an internationally important center for the development and introduction of the constructionist approach to educational technologies. INET researchers and teachers are involved in drafting training materials and in joint projects with colleagues in the United States, Czechia and Italy, to name but three countries.

THE ABSTRACT AND THE MATERIAL

Mathematical informatics, which can be called mathematics of the finite, is rapidly gaining in importance among the other divisions of this discipline; the teaching of mathematics is likely to follow this trends, which has come into being as a response to the challenge of the time. The study of mathematical informatics helps make a wide use of the environments of material, graphic, and linguistic objects, as well as of their computer images. One of the more advanced environments of this kind is LEGO. The three-dimensional world filled with LEGO objects helps master search algorithms and theoretical-multiple operations. The world of a robot or a turtle, or the world of string knots and the world of cooking effectively help shape the basic ideas regarding the modes of construction and descriptions of algorithmic processes. Going over the options or breaking up a problem into subproblems in a geometrical puzzle consisting of wooden parts or in a board game is mastered as a mode of activity in the real-life and then in the computer world.

This is one of the lines of integration of material and information technologies, in which material objects not only have direct roles and wills but are also symbols of abstract mathematical objects. Adjacent to this field is the use of the linguistic reality of the native tongue into which a child is immersed and of the other human languages, which are figuring more and more prominently in our life, as an environment of analysis, study and solution of problems of interest to the pupil and of project implementation. The methods used fuse the natural scientific, the mathematical, and the linguistic approaches to the study of life. Along with informatics teachers, these approaches are implemented in many schools by primary school, domestic science, and art teachers. The main properties of this approach are described in the manual «Mathematics and Language», which is used in hundreds of schools.

EDUCATIONAL TECHNOLOGIES

The other development trend of the «Technology» field integrates material and intellectual technologies. There appears a real and regular opportunity to master, within this educational field, technologies that are immediately applicable in other subjects on the school curricula. These technologies (the study of most of them comprises a «material» and an information part) include: information collection, including measurement; data recording; search for information (including via telecommunications); simulating; displaying; learning mechanical skills.

Educational activity in many subjects in the «Technology» educational field naturally assumes the form of experimental design and research. The key constructionist object environment are meccano games. A universal meccano game introducing the child to the sphere of material construction/design is LEGO, and to the sphere of computer construction – Logo. The most widespread computer educational product, Logo (adapted by INET for Russian schools), is extremely popular in the country. The latest Logo versions used in Russian secondary schools is MicroWorlds. This universal creative environment of technical design is best suited for modeling mathematical and informatics worlds and at the same time - this is very important - for the design work which results in real, albeit simple, multimedia products. INET has recently completed work on «wordless» Logo - *Pervologo* («Primary Logo»), a version which is connected with MicroWorlds and has a wonderful quality: children can use it before they can read and write and even before they have learnt the ABC.

Information support of the natural scientific and mathematical subjects is executed by the design programs of the «Living Geometry» series, which is the most impressive example of computer support of a whole discipline on the secondary school curriculum. INET has developed thousands of scripts for «Living Geometry» adapted to the basic geometry textbooks used in Russian schools. «Living Physics» has also proved its usefulness in the schools of Moscow and some other regions. Although we started with «screen» designing, in the teaching of the natural scientific disciplines computer design in computerized laboratories is of at least equal importance. Suffice it to recollect one of their most efficient uses, when the computer screen shows the chart of the movement (along one axis is enough) of an object held in the pupil's hand. There emerges a direct link between physical movement and a mathematical chart.

TEACHING ENVIRONMENTS

The key to the use of a computerized laboratory is not the range of various gauges and not quickness of action but the priority given in the teacher's educational doctrine to the scientific result of an experiment obtained independently by the student, and the procedure of processing and analyzing this result. Of course, of great value are the most «open» versions of such laboratories, where a student is able to do a great deal of constructing himself.

Despite their importance in the teaching of some subjects and «literal» implementation of constructionist ideas, design/programs are not the most widely applied teaching software. Even more popular are the various editors used to build the structures described in the next section and to present knowledge in a form intelligible to the others. The students have an opportunity to enter primary information in text, sound and visual form with the help of input devices, among which the «digital chamber» is perhaps the most commonly used one. Within the framework of the «Moscow Studies» project, which will be described below, the children interview their family, friends and old city residents, and then decipher, edit and make synopses of the texts. It is easy to see the difference between this type of creative activity and ordinary dictation or writing out an account of some story. Perhaps the most important software educational environment the secondary school needs is the simplest editor that would integrate the possibilities of databases, multimedia and Internet (hypertext format and telecommunication access). Of some use for Russian schools are computer exercisers and training programs. Among the latter the most important ones are those that teach typing: they ensure an efficient use of much of the other software. Many teachers are themselves fond of developing exercisers. Interesting results were achieved this year by A.Z. Bessmertny, one of Moscow's oldest and best-known teachers of English, who is working in hypertext environment.

Since in the secondary school, there is no definite boundary between administration and teaching, the former's condition is also a factor determining the near-term prospects of the introduction of new information technologies into secondary education. A high level of informatics and competent and democratic decision-making are only a few possible results of the use of up-to-date technologies.

A school's valeological parameters - objective assessment of the students' state of health - are considered by the high-tech computerized complex.

A major property of the secondary school teaching environment created by the new information technologies is the students' access to huge blocks of information in place of dissected information contained in most school textbooks. It is made possible by computer encyclopaedias and other information sources on compact discs or in telecommunication networks. We are currently in the process of transition from an informatics class to a school information environment incorporated into the global information space and integrating the information environments of the various school subjects, teachers and students.

NEW STRUCTURES OF HUMAN KNOWLEDGE AND LEARNING

Exploration of an educational field is ceasing to be a predetermined process of building of a linear organized structure of consecutively mastered - learnt and reproduced - fragments. It is turning into construction by students of an information network of knowledge, in which the substance increasingly moves from the peaks of the network to links among the peaks and conditions of application of some body of knowledge. Building a network is a non-determined process, which gives the student more options and unfolds in the global information network, Internet. The structures of the knowledge under consideration used to exist as our ideas about the world long before the advent of computers. However, it is information technologies that are probably the means which supports the progress of these structures, just as book-printing and television made an impact on certain structures and modes of intellectual activity.

The most natural field where these structures and learnt are the projects that merge information technologies with school subjects. The first project a student comes in contact with at school is the «Notebook»: the newcomer tells the computer (with the teacher's assistance, if need be) all about him/herself and soon gets access to information about all the children in the class. This information is contained, in particular, in a printout - the individual notebook. Together with the name-cards clipped on to the child's lapel, these notebooks constitute elements of information culture and information space created by the children themselves and identifying the child in the world around him/her. (You realize, of course, that in our project the notebook is the prototype of Internet). The project starts with a child's self-identification in his/her class and grows into activity aimed at incorporation into the hyperstructure of individual and collective information space of expanding fragments of the surrounding world in the past, present and future - the family, the nearest geographic space, the city, the Universe. The level of city merits special analysis. Moscow is changing at an extremely fast pace. History in the great variety of its manifestations is being made before our very eyes. To make an imprint of the world and people's ideas about it is a worthy research task, which the children accomplish with the help of a tape recorder, a video camera and a computer. There emerges a mosaic of individual information spaces united into a single hyperstructure accessible to all through Internet, the Great Integrator.

THE TEACHER

The role of the teacher in the emerging educational situation is changing and gaining in importance. At the crucial moments of the educational process, the teacher ceases to be a person who knows the right answers to all questions and evaluates the students' performance, and finds himself playing the role chosen for himself by the scientist and offered by us to the students. This is the role of a person who has forever retained a baby's wish to discover what the World is like. Our teacher does not stand alone. He is a part of the community. The technologies intended for use in the process of teaching are learnt by students in classes in which two teachers, the client and the author of the technologies, take part.

Personal contacts among teachers from different schools take place at the weekly sessions of the Technology Culb at INET. Telecommunications naturally involve teachers, their students and scientists into a never-ending virtual conversation. Russian teachers gain access to the ideas and work of INET researchers who have to do with secondary education; Internet offers an incomparably larger number of professionals a chance to share their knowledge with children and teachers and, most important, involve the latter into the endless process of learning.

DEVELOPMENT PRACTICE

Unlike the educational systems of most countries, the Moscow educational system has been lucky: for over 10 years, it has been headed by the same talented teacher and administrator L.P. Kezina. In the past year, the funding of education was much more scarce that in the preceding ones (although still much better than in most regions of the country). Apart from the adverse consequences, this fact obliged us to make yet another thorough revision of the development strategy of the information space of Moscow education. Our conclusion appears trivial enough, but no less important for all that: we should introduce new information technologies neither at the poorest nor at the wealthiest (in this sense) schools, and not everywhere equally, but where such technologies can do the most good, that is, the schools whose «near-term development zone» would benefit the most from the use of such technologies. One of the means of identifying a school's «near-term development zone» (in the sense referred to above) is this school's submitting an «application» for the relevant equipment. The need to fill out such an application would launch a discussion of the school's goals and the role of more advanced information technologies in achieving these goals. It turned out that even this fairly simple action substantially reduces competition among schools. Apart from the plans for the future, subject to examination are also the current status of the school and its past successes or failures. An example of evaluation parameter is the «keyboard index» - the teachers' skill in entering a text into a computer. Of course, even more attention is paid to the schools that have achieved results using their current modest equipment. An wonderful example of this kind is Moscow School #161, where O.G. Kutukova taught high-level informatics to her pupils and implemented really beautiful projects using just one class of machine, BK-0010.

This presentation leaves no room for describing all the significant results and trends in the progress of informatics in Moscow's secondary schools. Details of this subject can be obtained from the server of the Moscow Committee for Education.

The original is presented in Russian

Commission I

LESSONS FROM EXPERIENCE WITH COMPUTER IMPLEMENTATION

Betty Collis

ASSISTANT PROFESSOR, FACULTY OF EDUCATIONAL SCIENCE
AND TECHNOLOGY UNIVERSITY OF TWENTE (THE NETHERLANDS)

INTRODUCTION: THE CYCLE REPEATS ITSELF?

For over a decade, countries and regions around the world have pursued various initiatives to stimulate and support the use of computers in their educational systems. These initiatives have taken many different forms in different countries, some focusing on strategic support for hardware - and software - related programs, some on strategies more directly focused on curricular and instructional aspects of computers, some (fewer) on strategies for the school manager, and others (many) on different approaches to teacher education and support. Regardless of the focus or scope of the initiative, it appears that one type of result consistently occurs: a result that acknowledges the teacher as the key figure in the eventual success or lack of success of any computers-in-education initative.

The wave of social and technological developments that stimulated interest in computers in schools in the late 1970s and early 1980s appears to now be paralleled by a similar surge of interest in educational aspects of telematics. Throughout the world, the use of wide-area network capabilities for communication and access to new forms of information engagement is stimulating a wave of initiatives with respect to telematics in schools, particularly telematics via the Internet and applications such as e-mail and the World Wide Web. This wave could be seen as an iteration of the "computers in education" wave of 10 to 15 years earlier.

What did we learn from the first wave? To what extent can we expect the patterns and results of the first wave to reappear in a second wave, this time focused on the computer network rather than just the computer? What might we do more efficiently and effectively the second-time-around in terms of responding to a computer-related innovation at the strategic and policy-related levels?

These are the questions addressed in this paper. The conclusions that will be drawn are:

In critical ways, the "Internet in education" is a second iteration of the "computers in education" phenonmenon of the 1980s.

In many critical ways, we can expect the same sorts of implementation results; however the unique characteristics of the World Wide Web, coupled with differences in society compared to a decade earlier, suggest that certain breakthroughs in implementation success will occur in this second wave.

The experiences of the field and of decision makers with respect to computers in education in the 1980s present an interesting legacy with respect to networking in education, in some aspects positive and in others a burden.

SKETCHING THE ITERATION: FROM COMPUTERS IN EDUCATION TO COMPUTER NETWORK APPLICATIONS IN EDUCATION

In the 1960s, research initiatives began relating to the use of computers for educational purposes and the study of computer science (called by different names in different countries) became established as academic and professional domains. By the 1970s there was already considerable experience with the development of computer-based learning systems; for example, Prof. Jef Moonen in The Netherlands used the PLATO environment to create a complex mainframe-based system to support the learning of statistics at the university level that is still in use today (in an evolved version, of course).

With regard to teachers and schools, however, the breakthrough came through the impetus of a social and technological phenonmenon: the personal computer. In 1979 and 1980 in particular, an explosive synergy occurred: the personal computer afforded personal control, allowing the individual to work independently of mainframe computers. Society saw this as a revolutionary, romantic and powerful new opportunity; education was pushed by the same energies. Computers could revolutionize education, could even revolutionalize the process of cognitive development of the child, and in more practical terms, could bring new competitive possibilities to schools. Concurrently, there were fears as well: computers would replace the teacher and would distort the social development of children at the same time as they would disenfranchise large groups (such as girls) from status and success.

It is interesting to compare the start of the computers-in-education wave of the early 1980s with the "information highway" wave of the mid 1990s. My argument is that we are now experiencing a second iteration of what we experienced before. Here are some major points of similarity:

The computers-in-education wave did not occur in a vacuum, either technologically or in terms of educational experience. As noted earlier, computers had been studied and used in education in many ways prior to the "personal computer" breakthrough of the late 1970s. But the personal computer provided the "trigger event" to unleash the first wave of broadscale educational activity. Similarly, networks, including the Internet, have been in use in educational settings for many years, before the trigger event of the World Wide Web (WWW), has unleashed the second wave of broadscale social expectation. The trigger event idea is critical; a trigger event is rather like a break in a dam. Much water must be accumulated behind the dam wall before the pressure to erupt becomes inexorable, and then when the breakthrough occurs, the flood cannot be stopped.

Push Factors	Computers in Education, 1980	The Information Highway and Education, 1996
Technological Breakthrough	-the microcomputer	-public access to the Internet and the WWW
Social Response	-we must have a computer, in our homes, in our schools...	-we must be able to get on the Internet, in our homes, in our schools...
Social Vision	-personal computers will revolutionize society and will create powerful new opportunities for those who can handle them	-the information highway will revolutionize society and will create powerful new opportunities for those who can handle it
Commercial Push	-a vast new market for goods and services	-a vast new market for goods and services
Social Expectation	-schools must not be left behind; all students must be computer literate	-schools must not be left behind; all students must have "driving licenses for the information highway"
Vagueness	-metaphors and predictions are strong; results are anecdotal	- metaphors and predictions are strong; results are anecdotal
Pioneers show the promise	-both in theory and practice, there are impressive ideas and examples of how the computer can enrich and re-engineer education	-both in theory and practice, there are impressive ideas and examples of how the WWW and other network environments can enrich and re-engineer education
Educational decision makers must and do respond	-every school must get computers; funding must be found; new initiatives are needed; policy and strategy are needed...	-every school must be able to access the Internet; funding must be found; new initiatives are needed; policy and strategy are needed...
The overall movement is unstoppable	-computers are pervasive throughout society	-interconnectivity via computer networks is pervasive throughout society
The rich will get richer...	-an incentive, and a fear	-an incentive and a fear

WHAT HAS HAPPENED IN THE FIRST WAVE?

We all know the story of the past 15-20 years with respect to computers in education and how these early hopes and fears have worked their way out in practice; however, each of us may see the results through a different optic and with different interpretations. The old adage of seeing a cup as half-filled or half-empty relates to our interpretation efforts. There are many different reports and analyses of what the results of the first wave of computers-in-education may be, and there have been a number of attempts to synthesize these results at the international level. In a new book, "Children and Computers in School" (Collis, Knezek, Lai, Miyashita, Pelgrum, Plomp, & Sakamoto, 1996), three of the largest and most carefully controlled of these international comparative investigations are further synthesized. Conclusions such as the following 11 points seem to be justified when one looks at the international picture. To a certain extent I offer these as my own interpretation, and of course my view of the cup may seem half-full or half-empty to others.

1. Into the system:

Computers are present in educational institutions throughout the world, with computer rooms as standard as a school library or cafeteria. Every educational jurisdiction spends money in a regular way on some aspect of its computer provision. Computer-literacy courses or modules of some sort have become standard practice. Teacher education includes some acknowledgement of the need to prepare teachers for the use of computers in education. Students have some level of functional skills with computers. Many educational professionals have their identities and job definitions related to computers.

2. First-level problems affect everyone:

So-called "first-level problems" confront every step of computer use in schools, by teachers, by students. These problems are the same throughout the world. Individuals fight with them, at great cost of time and energy, until gradually an institutional response removes some of the personal burden. Computers do not work; software crashes, software is too difficult to install or understand, software is too expensive; there is no way a teacher can have a computer on his desk in the classroom (there may not even be an electrical plug anywhere near his desk even if he had a computer and had a place to set it); there is no projection device so that students can see what the teacher might want to demonstrate, computers are fixed in the computer room and not accessible when and where the teacher can manage their use by his students; there are not enough computers, the computers are too old, too slow, too limited in memory; the teacher does not have time or a place to work personally with a computer, the teacher has no time...

3. Second-level problems are also persistent:

Gradually, first-level problems are reduced (never eliminated) through a combination of personal efforts on the part of committed teachers, and institutional and system-wide responses. But a more challenging level of problems remains. These second-level problems are also familiar throughout the world: teachers do not see how to integrate computers into their instruction; teachers and decision makers are not convinced of the payoff of computer use on the real markers of school achievement-student examination results: no matter what approach to teacher inservice is attempted, it is not enough; no matter how hard we try, software is not good enough or appropriate enough.

4. Good things are happening...

Throughout the world there are countless examples of good experiences with computers in individual lessons and with individual teachers and students. The results of these good experiences are elusive to measure with tests or to demonstrate in terms of any changes on broadscale educational output, but those involved know that, quality instructional moments are occurring.

5. Diffusion is difficult:

The good things that are happening are related to special people or situations and do not diffuse much into mainstream practice.

Good teachers are associated with good examples of computer use. There is no evidence that the computer use made these teachers into good teachers. A good teacher sees possibilities in a powerful technology, sees a way to realize them in his own situation, and has the energy and persistence to implement them usually at cost to himself. In contrast to the more-idiosyncratic success stories, substantial, long-term, expensive initiatives are needed to sustain computer use among the mainstream of teachers. Diffusion into practice has not yet much occurred.

6. Different policy and strategies come to similar ends

The above patterns seem to occur regardless of what policy or strategy has been employed.

There are many different models for regional or national support of computers in education, ranging from indifference to highly integrated. Yet the above five results seem to repeatedly emerge. There are differences related to policy to be sure, but at a broad level the results seem to be similar. There are computers in schools, it is difficult to use them, it is even more difficult to see how to use them in instructional practice, some teachers do find a way and are associated with interesting and probably important learning experiences, diffusion into mainstream and meaningful practice is difficult and does not much occur. That so many different national policies and strategies, at so many different levels of cost and activity, generally lead to the same result, is in itself an important observation.

7. Cost-effectiveness is not demonstrated

There is no broadscale evidence, yet, to equate the amount of money (indirect and direct) which has been spent on computers in education with a corresponding payoff in terms of educational outputs. We do not seem to be able to say that a country's expenditures and efforts with computers in education have resulted in noticable, sustainable system-wide differences in student achievement.

8. Not to fear...

We can be comforted that many of the fears expressed at the start of the first computer wave have not materialized. Computers have not replaced teachers; computers have not made the school obsolete; computers in schools have not turned children into anti-social problem cases, students generally have little "computer anxiety" and assimilate some level of computer-use skills, enough to function in their societies, through social osmosis regardless of our concerns with curriculum or instructional units for computer literacy. "Keyboarding" does not have to be taught. The life of the school goes on....

9. Not to gain...

With the exception of a handful of large companies (I have read that eight US companies have nearly 50 % of the world market of the world market in educational software), little or no money is being made from educational software. The software that is pervasive in schools is that which is pervasive in society as a whole, or is provided by a particular local initiative. Despite the success of the eight large companies, a market for educational software does not really exist unless propped up by funding. Creating educational software that is portable among countries so that the market for its use is increased has rarely occurred. Once national or regional initiatives supporting the dissemination of locally-made software packages are finished, the locally made packages do not further disperse (although they may continue to be used in pockets of local settings).

10. From subsidized exploration to... it's withdrawal

The computers-in-education wave was fueled by enthusiasm, by predictions and visions, and by the simple need to be involved in it. But throughout the world, the broadscale initiatives that were established as special national programs or special collaborations can no longer expect to receive the funding support that was available a decade earlier. There is a pendulum effect of a sort: ministries and decision makers are saying "Ok, good, we had a big project, the project succeeded in putting x computers in x schools, providing x hours of training for x teachers, supporting the production of x pieces of educational software with accompanying instructional materials, and funding x research and evaluation projects from our university partners. We learned much from this project, good. But now the special project must be over. Funding is scarce; other special projects demand our attention. If you want more money, show us the facts, the data, the results. We cannot afford to finance more exploratory and preparatory studies...".

And teachers are saying, "Ok, I tried it, but it didn't really work for me, so don't expect me to respond again to the next workshop or project. I really must get back to my real work...".

An the school administrator is saying, "Fine, we have a computer room, it is always filled, Teacher x does a good job in there, so let us now turn our attention to other things. We certainly don't need. days off for teacher workshops about computers in education; we did that..."

11. The teacher is the critical variable in computer use in the school setting, but not the critical variable in the student's computer use outside the school

Whatever is done or not done by policy makers, researchers, teacher educators, and vendors, the teacher is the critical variable in the use and impact of computers with his students in his classroom. Conversely, what students do with computers outside of the classroom context, in their homes and in society more broadly, does not seem much related to what they do in school or to what their teachers do or not do.

Must or Should We Re-Invent the Wheel? Lessons from Past Experience and Their Application to Telematics in Education

Given these 11 conclusions about the first wave of computers in education, what are my predictions about the second wave, relating to wide-area networks in education? I will repeat the 11 conclusions and follow each with a comment and a suggestion. These are my own views, presented for debate.

Results from the First Wave	Implications for the Second Wave
1	2
1. Into the system:	We can expect expect access to the Internet (or whatever it evolves to) to be as common in schools as having a telephone number or a computer room. We can predict that students and teachers will be as familiar with the WWW (and its evolution) and with e-mail as they now are with faxes and word processing and automatic money machines and pincodes. *Lessons from the first wave?* Economies of scale can help this process of system-wide presence, but the technology will change so quickly as will the social pervasiveness of the technology, that only the most strategic decisions relating to infrastructure access and cost reduction need be the focus of policy and strategy. We do not need to teach Internet literacy...(although wisdom is a different matter).
2. First-level problems affect everyone:	Schools will find it very difficult to offer useful amounts of Internet access to students or teachers. Classrooms will have no network connection, school networks will not easily adapt to Internet connectivity, server connections will crash and having a teacher in the school technically able to solve Internet-related problems will be very difficult. Costs and security issues will increase compared to stand-alone computer use. *Lessons from the first wave?* Anyone advocating any form of Internet use should walk through each step of access problems with a classroom teacher in the actual classroom setting. A three-partner discussion, between the teacher, the school decision maker and a representative of the regional or national strategic team, must occur so that "little problems" such as no printer access in the classroom and no projection device are given respect and attention.
3. Second-level problems are also persistent	Identifying educationally relevant uses of the WWW that teachers can see as applicable and to their own needs and feasible in their own situations needs careful attention. A major possibility for such idenification is the fact that the WWW provides access to resources not available in the school through a single user interface and a single sort of search tool. But the fact that "everything is available" will not necessarily mean the teacher sees or accepts the usefulness of "everything" in her practice, especially as "everything" implies junk as well as quality. *Lessons from the first wave?* Look for one convincing application of the Internet that is solidly useful in the particular school or teacher culture. Build on this, show it in practice, get evidence to convince teachers that this particular application is "worth it", and then do all possible to make it easy for them to make use of the application itself.
4. Good things are happening...	Very good things are happening, particularly with respect to applying the functionalities of the WWW in learning settings. The fact that WWW functionalities can be used in an "intranet" context (that is, within the school's own local area network"), means that their value does not have to involve access to the Internet with the cost and quality control issues that entails. *Lessons from the first wave?* Look for examples of "good things" and support the teachers involved. Give them time and opportunity, and recognition. They are the pioneers; they may also be the only ones to really exploit the medium in the short-term, so use limited funds to support them rather than to try and engage everyone.

5. Diffusion is difficult:	Some teachers will make good and powerful use .of network opportunities, but we can expect that most will not, at least in the near future. ***Lessons from the first wave?*** Similar to Point 4 above, it does not seem to pay off to attempt to provide across-the-board inservice in terms of payoff in practice. The "trigger event" strategy (Point #3), coupled with reduction of first-level access frustrations (Point #2), and support of one's creative pioneers (Point #4) will probably be more effective than national plans for "Internet skills for teachers" or expectations of system-wide implementation or expectations of vaguely understood goals such as "being a citizen of the global community".
6. Different policy and strategies come to similar ends	When a flood has begun, it.will continue. Thus social pushes for access to and use of the Internet, the WWW, and their follow-ups are occurring regardless of what policy or strategy is chosen for the schools. ***Lessons from the first wave?*** Decision makers need not invest substantial effort looking for a "best approach" or policy; a powerful idea will find its way. Look for the local-relevant "trigger event", reduce the most frustrating access problems, support your good and creative teachers; this can be done with smaller-scale initiatives as well as big national projects. There is no best way.
7. Cost-effectiveness is not demonstrated	Just as it has been difficult with computers in education to show cost-effectiveness evidence, we can expect it will be even more difficult with networks in education. But we do need to try. ***Lessons from the first wave?*** We need to collectively take the issue of cost-effectiveness measurement very seriously. We must move beyond theoretical predictions of great benefit to some sort of objective evidence that increased access to wide-area networks is paying off. Thus we must start now, gathering some types of useful baseful indicator data, so that perhaps in five years we can say, "Yes, but before we used the WWW extensively, students only reached the x level of some kind of attainment, but now we can demonstrate that students are reaching a better level." Will we be able to say this in five years? Perhaps we should start by asking teachers: What are your problems and what are some indicators of those problems?
8. Not to fear...	Newspapers around the world featured articles in 1995 about the dangers to children of the pornography on the Internet. Governments have even taken initiatives to "protect" children from this danger, through technologies such as "chip cards" and special agents, and through legislation. ***Lessons from the first wave?*** Given the increasing access to the "big world" and its evils that bombards children in every part of their lives, it does not seem to be a cause for concern that school use of the WWW is going to corrupt the morals of our students. Nor does it seem that we need to anticipate sociological or psychological damage from network use, any more than it occurred from personal computer use. More seriously, we do not need to fear that schools will disappear and teachers will be replaced by some virtual equivalents.
9. Not to gain...	While the Internet will open up new channels to the international dissemination of electronic learning materials, there is not likely to be a corresponding response of purchase orders via a CGI-forms from within WWW pages. Teachers and schools will want free materials or services subsidized by their local jurisdictions; a commercial market for educational network services is not likely to develop. ***Lessons from the first wave?*** It is unlikely that commercial groups will make a profit from school access to the Internet. In contrast, more use will be made of teacher-made and student-made materials, because these will be available for free. This means that decision makers cannot expect commercial interests to support schools' Internet access. Funding will have to come from educational jurisdictions, and increasingly from the individual parents and teachers in a school. Of course, this will lead to inequities in educational opportunity reflecting the inequities in society; networking will not reduce them.
10. From subsidized exploration to ... its withdrawal	Here we will suffer from being the second wave. Society, and teachers, are rather tired of computer-based innovations, and will be less tolerant of spending energy and money on them. ***Lessons from the first wave?*** Make sure the Internet-enthusiasts have good awareness of the computers-in-education history or a school or district or country. This history will flavour all new computer-related initiatives in a way that the newcomer, filled with passion for the WWW, is likely to underestimate. And also, there will be less tolerance for experimenting among teachers who already had poor experiences with computers. A justifiable skepticism about "fads" in education must be anticipated and respected.
11. The teacher in the critical variable	In the classroom, the teacher is the gatekeeper and the filter; the teacher, not the visionary, not the vendor, not the service provider, not the ministry decision maker. A good teacher may do very good things with network opportunities; a weak teacher will not no matter how we try with strategies and inservice. ***Lessons from the first wave?*** We have learned that teachers are very much influenced by and helped by each other. Stimulating and supporting teacher networking with respect to ideas about classroom applications of the Internet seems to be a good strategy decision.

CONCLUSIONS: IS THERE SOMETHING NEW?

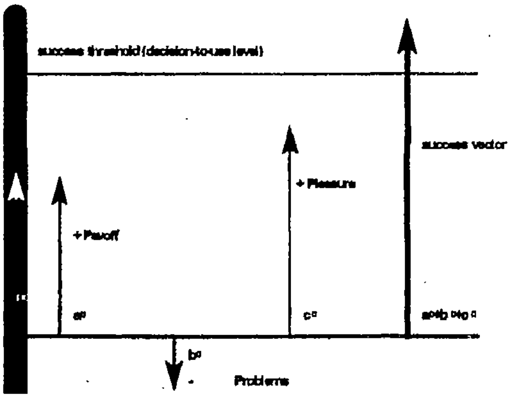
I began this reflection by asking if we could learn from our computers-in-education experience with respect to our expectations for teachers' use of networks particularly the WWW accessed via the Internet, and I have argued that there are many insights that can be applied. I do think, however, that the second wave does involve some things which will make a difference in terms of increasing the likelihood of implementation. Focusing particularly on teachers, I think that:

• The common and easy-to-use user interface of WWW browsers will be as helpful and atrractive to teachers as it is in general in society, thus lowering some of the traditional barriers to teacher use of computer software.

• The ease with which the WWW with its search engines now allows us to access ideas and examples and images and materials through a single user interface is something which has never happened before. Such single-frontend ease and international access to materials did not accompany the computers-in-education movement. We could read about an interesting software package, but had no way to see it or use it. We have finally made a breakthrough in the traditional dissemination bottleneck, and the breakthrough is at many levels. It is at a personal level: teachers can look for and decide for themselves what they find interesting, not needing to wait for the filtering process through committee and resource offices. It is at an idea and energy level: there are many, many good arid creative sets of materials being made available via the WWW by teachers and students that can now flow into the international community in a way that was never possible before. The cost of this freedom is loss of quality control, but teachers as professionals must be able themselves to judge if a resource is useful or not.

• Another thing which is interesting is that the WWW supports teachers' access to resources, to units of learning materials which can be integrated into one's own lesson and situation. We did not succeed with educational software, I think, because the teaching act is too personal to be handled by software to a teacher's satisfaction. But finding and making use of good resources and information is something different. Teachers will, I think, be much more likely to see the use of good quality images and example materials that they can embed in their own lessons than they have been likely to see the use of a software package that tries to teach.

• The WWW is a flexible and universal medium; platform independent and capable of being used in many ways and with many different media forms. The surge of creative development of WWW technology is a breakthough in society as a whole. For a while at least, ordinary people can do powerful things with the functionalities of the WWW, taking us back to the creative feeling that fueled the "computers in education" breakthrough of the late 1970s.



The "3 P" Model to predict implementation of an innovation in instructional practice

I and my colleagues have earlier argued that the likelihood that a teacher accepts a computer-related innovation into his or her practice is a function of three variables: expected payoff, level of problems that have to be overcome, and instrinsic pleasure in being involved with the innovation. We call this the "3P" Model (see, for example, Collis, 1996), and have seen it to have explanatory value in many different settings. The 3P Model says that the vector sum of Payoff, Problems, and Pleasure must be sufficiently positive in order for usage to occur. In general, "Problems" is a negatively-valued vector; pioneers and enthusiasts bring high value to the "Pleasure" vector (and also predict much higher values for the "Payoff" vector than do non-enthusiasts.). The figure below visualizes the model.

In the diagram, the innovation is likely to be used by a teacher in practice, because it is perceived having relatively low problems associated with its use compared to the perceived payoff and pleasure.

The breakthrough in network usage that is now occurring via WWW developments appears to be contributing to a reduction in the negative value of "Problems", an increase in the number of persons experiencing a "Pleasure" feeling with network use, and thus in both real and perceived ways is suggesting a positive "Payoff" vector. The personal computer breakthrough in the late 1970s changed the "3P" relationship about computer use for the teacher and stimulated much hope in Payoff. It may be that the breakthrough of WWW functionalities and the World Wide Web itself will support a positive enough "3P" vector sum so that the teacher will implement the innovation into her practice to a greater extent than has been the case with computers.

THE DEVELOPMENT AND EXPERIMENTING IN THE FIELD OF EDUCATIONAL SERVICES USING INFRASTRUCTURES OF INFORMATION SUPERHIGHWAYS

Gérald Lizee

CHAIRMAN OF THE EXECUTIVE COMMITTEE OF THE INTERACTIVE DISTANCE EDUCATION SOCIETY, MONTREAL, QUEBEC (CANADA)

1. THE PROBLEM

The Society of Interactive Distance Education (Société de téléformation interactive: STEFI) is a consortium of twelve partners, working in the field of education, electronic superhighways and distribution of information. This noncommercial organization comprises educational institutions representing all educational levels (primary, secondary, higher and additional professional). The aim of the consortium is to propagade, to develop and to provide educational services by means of information superhighways.

The members of the STEFI consortium believe, that the key to the success of our UBI-Education project is almost the universal use of TV sets and what is most important, that it is the center of all sorts of common activity of the modern family. They regard the start of the UBI network in Saguenay localities as a wonderful opportunity to extend their services owing to the «omnipresence» of the network, which is being designed for the first time it will provide practically all Canadians with a broad spectrum of telematic services.

The UBI project includes several experimental subprojects, offering to the users new specific services, which will be fully appreciated in the future and will allow to realize all kinds of activities connected with education:

1. **Pedagogical support:** educational programs, self-training programs, special pedagogical programs for control and self-control of knowledge.
2. **Teleclass:** interactive distance education through multimedia means (on-line and off-line modes).
3. **Electronic library:** the access to information resources and databases.
4. **Administrative services:** submission of applications, entering on the list of students, information about students' progress, tuition charges.
5. **Information services:** information on programs and educational establishments, their location, classrooms, lecture halls and time-tables.

2. MEMBERS OF THE CONSORTIUM

Participants of the UBI project are universities, colleges, school commissions and communication enterprises, working to extend information and services, provided through electronic superhighways. The association STEFI integrates the following partner-founders;

- University of Quebec, Montreal
- University of Quebec, Chicoutimi
- Teleuniversity
- General educational and professional college, Chicoutimi
- General educational and professional college, Jonquiere
- Center of distance education of Rosemont College
- School commission, Chicoutimi
- School commission, Jonquiere
- School commission, Valin
- Radio station «Radio Quebec»
- Radio station "C.A.N.A.L".
- Consortium of the UBI project and Vidéoway Multimédia.

Another two organizations of Saguenay localities have joined Interactive Distance Education Society as associated members to promote the project at a regional level as much as possible:

- Regional office of the Ministry of Education
- Quebec Society for Labour Power Development.

3. UBI-EDUCATION PROJECT

The UBI-Education project comprises a variety of projects aiming at designing, development and introduction of new educational services through the UBI electronic superhighway and making these services available for every family. In the intermediate term perspective the STEFI consortium seeks to solve one of the problems concerning schools, colleges and universities of the future by developing projects of the informational maintenance of education whose realization would provide teachers and students with more powerful technological means thus promoting and improving education. The scheme given below shows how we look at the virtual school of the future, where all services stipulated by the UBI project are already introduced and which offer new opportunities to the three main participants of the educational process - the teacher, the student and the manager.

All members of the consortium (first of all, educational institutions on three levels of education) take interested in the realization of all the projects stipulated in our program of development. Their list is given below.

PEDAGOGICAL SUPPORT

Curricula

To make the adaptation of available curricula to the work on modern computers easier the consortium suggests that it should develop and supply the Ministry of Education and the firms producing educational software and distributing it on a commercial basis with the reference book on conditions of education, and also with the directory of curricula for their selection and adaptation.

<table>

</table>

Software for self-training

This project aims mainly to help pupils of primary and secondary schools offering them auxiliary educational software, such as oral and written electronic homework thus ensuring self-control and making it possible to correct mistakes.

Special programs for pedagogical control and self-control of knowledges

Special programs for pedagogical control and self-control of knowledge contain the electronic directory for parents on problems of primary and secondary schools (programs, teaching materials, etc.) and software to check up children's homework, and also electronic training programs to prepare them to SEC (School Education Certificate).

TELECLASS

Distance education class

This class will help to create an original innovative educational environment. But before this class is started it should be created and tested.

The concept of the teleclass is based on the fact that the UBI platform makes direct distance learning of a large teleaudience possible. The teleclass is intended for lessons with a large number of students so that it would be possible to justify large expenses and to reach the maximum possible economy of funds. For example, in such a studio-class equipped with the server and the central control panel, it is possible to transfer several parallel images, all functions of the new information technologies and computer data exchange, as well as the dialogue between the teacher and students, not only with a small group of those present; but also with a significant number of students in their homes. In case of need the teacher can supplement his explanations with multimedia-documents.

Supplementary electronic educational tools

Supplementary electronic educational tools enable schoolchildren or students to use the potentialities of new information technologies to enhance the efficiency of learning in the teleclass doing diagnostic and training exercises with tests to prepare them for the examinations, and also using additional electronic learning modules.

ELECTRONIC LIBRARY

The access to information sources and databases

This service enables to find the necessary literature (monographs, essays) in the database or to compile a bibliography using key words. Such an additional service as the request for printed matter which can be compiled using electronic catalogues, provided with the searching system.

ADMINISTRATIVE SERVICES

Submission of applications

After the student acquainted with the information about educational programs, he may ask for additional information or documents and to start filling the application form and other papers.

Entry on educational courses list

This service enables the student to contact with an educational institution he get intrested in and enroll in the chosen course by filling an electronic application form and sending it through our network.

Information about marks and obtaining extracts

Due to this electronic service pupils (or their parents) can read their test book or their student's book which appear on the screen. They can also make a request for an extract from these documents or if it is necessary, to ask for a printed extract, which is an official document.

Payments for services

Payments for services through our network by credit cards and from the so-called "electronic purses" is mainly for students of universities and colleges.

INFORMATION SERVICES

Information about programs and educational institutions

This service can be used by students and their parents.

Information about the location of educational institutions, classrooms, lecture halls and time-tables

This service will enable everyone to get the necessary information, to pass it quickly and safely to those who need it, and in some cases to pass urgent information about unexpected changes.

4. STRATEGY OF INTRODUCTION

At the first stage, when the infrastructure of the UBI network will include 80 per cent of families in the Saguenay localities, the STEFI agency will take advantage of it to cover the remaining parts of the population of this region as soon as possible. To find out the forms which can meet the needs of various social groups for education and training in the best way, new pedagogical models of distance education will be tested.

The STEFI has chosen the strategy of introduction of their educational services using many ways. Taking into account the technological compatibility of the game TV set (with a game station and network interface) and personal multimedia computer, which is linked to the Internet, the STEFI will adapt their services developed for the application of one type of means, to work with other types.

The new products and services being developed by the STEFI enable to concretize the model of the virtual school - the information space, which will make it possible to connect students, teachers and the administrative staff.

Discussion

MULTIMEDIA IN EDUCATION. WHY SO SLOWLY AND HOW TO ACCELERATE PROCESS OF INPLEMENTATION

S.A. Christochevsky
HEAD OF DEPARTMENT OF THE INSTITUTE
OF PROBLEMS OF INFORMATICS,
RUSSIAN ACADEMY OF SCIENCES

From the experience of practical realization of computerization in education in various countries the author notified in the beginning of the process of mass installation personal computers at schools that we must not be waiting for fast revolutionary changes in the process of education. Nevertheless the break between achieved high level of information technologies and insignificant achievement in their use in education surprises. Why it is not enough successful examples? We shall try to analyze why the process of introduction new information technologies, in particular the multimedia technologies and distance education is so slow.

Basically, in this material we will speak about the problems of secondary education, but a lot of them can be distributed also to the higher school.

SOCIAL FACTOR

At first it is necessary to deliver a social factor. The process of informatization of education, together with using the multimedia technologies in education is more depending on human factor, that is on how proposed innovations will perceive by the teacher. We shall try to realize a teacher's position. Usually he has agreed and valid method of teaching, he spends not a lot of time for preparation for lessons and suddenly he must change the customary style of teaching, he should begin to work with computers, he has to use them for doing lessons and etc. Thus nobody has evidently proved him, that the using of computers helps to improve the process of education. Besides, frequently, the teacher does not know well the opportunities of the computer, could not work with it.

We shall assume, that at school there are the sufficient number of computers. Then, if the teacher will decide to use them in teaching process, he should spend considerably more time for preparation to lessons, and not at home in comfortable conditions, but in educational institution under the looking of the expert in informatics. Really, he is compelled to ask the help from colleague (because it is difficult for him to be prepared to lessons independently) and thus he becomes in a role of the schoolchild, that strongly touches vanity of the teacher. While it will be more new words and concepts (computer, expert system, base of knowledge, network, method of the projects, multimedia, Internet etc.), that there are more passive resistance of the teacher to the persistent requirement about using of the computer in educational process. But, and this is the main, an offered way of use of computers in teaching process is completely alien for him. Why is it? Before we will address to the history of a question we shall carry out some analogies.

SOME ANALOGIES

Active using of computers in education has begun more than ten years ago. Let's recall, about what we then dreamed and wrote: computers will much change the education; we shall manage to train the students on best methods, created by best methodists and programmers; in short term all system of education will change etc. Whether have we reach the delivered purposes? It is necessary to say honestly, that we have failed. Whether it means, that the computers should not be used in education? I think, that the overwhelming majority will consider blasphemous even statement of such question.

Practically the same enthusiastic words we are using now, but in combination with other new «idols», on which an information community is offering prayers: multimedia, CD-ROM, Internet, distance education, united information space etc.

At the same time the real situation with introduction of multimedia-computers in schools leaves to desire best. In Russia, for example, so far one third of schools has not computers in general. May be is it better the situation in USA? There near half of computers installed in schools have become outdated for a long ago: in the total number of computers of Apple Computer Co (this number is about 63 % of total number of computers in schools) only about 30 % are Mackintosh type, and the first models have become outdated for a long time. Is it necessary to speak about multimedia today? Without fail. It is necessary to analyze our errors and to make correct conclusions for successful progress. The computers should be used in education, but it is necessary to put more real ultimate objectives.

SOMEWHAT ON HISTORY OF APPLICATION OF INFORMATION TECHNOLOGIES

The education always carried out with the using of a certain method of teaching. A *method,* if to translate it to the technical language, is the *technology,* not the technology of the production process, but of the training process. The technological process always means that there is a definite sequence of actions for achievement of result and it even is as algorithm. Where is a place of the multimedia-computer in this technology?

Multimedia is the joining in one user product of the text, graphic arts, audio- and video-information, animation. It does not mean, that simultaneously on the screen appears some video-subjects, photographs, textual fragments. More faithfully, multimedia-technology is the opportunity with the help of the computer to proceed from illustration to videofragment, then to text, again to photographs, the opportunity to-near the sound commentary to it, thus for user is added an opportunity of a feedback, that is property of interaction. The order of using information elements is defined by the teacher or student.

Now should at least perfunctorily address to the history of appearance and use of components of modern multimedia.

Text has appeared for long ago and is familiar to all from books. The books are widely used in education, they are main educational manual.

Black-and-white graphic arts has become to be used in books in the last century, in many events has improved the understanding of the subject of study.

The colour illustrations has appeared rather recently, already at our century they have come in our life. Together with text they are broadly used in educational process.

Sound (audio) - radio, tape recorder etc. have received the mass distribution from the middle of our century, they have received distribution at school practice, may be, only when studying foreign languages.

Cinema (at first "Great dumb", and then as a sound cinema) was spread from the first third of our century. In the educational process it has not received the wide application due to the complexity of the equipment and problems, connected with flammability of film.

Video image (TV, video recorders, laser players) has come up for the second half of our century. It was expected, that the using of video in the educational process will allow sharply to raise a quality of education, since it will be possible to spread advanced teaching experience, best lectures and lessons unless on the whole world, at least, on whole country. Besides, it was expected the significant improvement in correspondence (on - modern - distance) education.

It is necessary to pay attention, that the best results in sphere of education are given by using that is invented more than century ago. The other innovations of high technologies (or components of modern multimedia) in the next once have disappointed of admirers. Radio and tele-lessons could not make a competition to usual day school and university system. The linguaphone rooms did not learn masses of people to foreign languages and etc.

GENERALIZAION

We shall try to generalize resulted sketches. Each new technical facility begins to give good results only when the new generation of the teachers will growth up and they will be ready and wanting to apply the specified technical mean with the desire, and also when teachers, who could develop a methods on using new technical facility in teaching process, will appear in sufficient quantity. They will create rather large number of examples, on the basis of which even average teacher can use this technical innovation.

Really, in each country accumulated the large methodical experience, but, alas! — with using the old facilities. To replace a strategy on the new technical facility - not each under power. Simple analogy. The development of a film-industry has made alive a new professions — of a scenario-maker and the film producer. The good photographer could not become a film producer, as he was accustomed to think in static images, its slogan is "To stop, instant!", but cinema requires as once of dynamics, movement. On the other hand the film producer can not replace scenario-maker, though he can be the co-author of the scenario, as prompts to a scenario-maker possible realization of the conceived scenario.

Today we have approached to that moment, when technical facilities much outstrip opportunities of the modern "average" teachers to perception of these facilities and more so using these means. It is necessary to ascertain,, that there is the gap between revolutionary development of information technologies, technical facilities and the evolutionary development of person. The similar fact was paid attention ten years ago, when was rather fashionable to speak about *retraining* of the teachers, *training of the teachers* of the teachers (that is those, who learns directly teachers and tutors) etc.

At the same time among teachers and methodists (which are the experts in the field of technique of teaching) a layer of people, who can write a qualitative scenario of a training product for realization on modern multimedia computer, is practically completely absent. On the expert estimation the overwhelming majority of computer teaching products is created by former programmers. In this connection the following recommendations are expedient:

- the preparation and retraining of the teachers should go by *outstripping rates in all countries. Only in this case* reduction of gap between the appearance of a new technical facility or information technology and its mass effective utilization is possible;
- in all higher educational institutions it is necessary to enter new teaching subject on using of multimedia-products in the teaching process;
- it is necessary to begin education in higher educational institutions of the students on specialty pedagogue - scenario-maker (or methodist - scenario-maker).

WAYS OF THE PROBLEMS DECISION

In the conceptual sights on informatization of education it is necessary to carry out updating of the purposes. It is necessary to select the following purposes.

The informatization of education, providing the access to .information within the framework of uniform information space. The selection of the information should be made in the view of recommendations of the teacher and according to national and religious customs. Thus in the education will be done the greater emphasis on preparation of the abstracts on problem, reports and printed work.

Mastering a computer as an information instrument *so* as contact with computer came of difficulties, not exceeding those, which we feel by using a pen.

Education at schoolchildren and students of information culture. Otherwise they can not productively use information superhighways for work, and "will be lost" under avalanche of the information, which they will request and possibly send by modern communication facilities.

As remote prospect (it is necessary not to wait miracles not having prepared ground for them) the organic computer integration in the teaching process is considered in new its quality which can ensure upheaval in education, but *not revolutionary,* as we all assumed early, but *evolutionary.*

What is it necessary to do, that the "average" teacher, at least once, did not object to use a new information technologies in its work? It is obviously possible the following.

1. *Orientation of public opinion* on the duty of using the computers (as an *element of qualitative education)* when teaching some subjects. For this purpose it is necessary widely to use means of mass-media.

2.. For lessons or lectures teacher or lecturer should be given as *much as possible «friendly» computer,* for example, computer of type Mackintosh, though for this it is necessary to pay in direct sense of this word (Mackintosh costs a little bit more, than IBM PC compatible computers of a standard configuration). Nevertheless, this is the most favorable investment of the capital, as the purpose is not simply installation of computers in educational institution or purchasing not so expensive secondhand computers, but productive using of computers with the purposes of teaching. We shall note, .that productivity of the processor, tact frequency and other technical characteristics of the computer are not so important for teacher as «friendly» of hardware-software means and integrated approach of the given decision. The teacher should not spend time for selection of the computer configuration, the most suitable for his subject.

3. It is necessary to offer to the teacher new *methodically worked models of using computer* (or computers) in teaching room. Today in Russia, for example, only one decision is recommended to the teacher - *lessons in computer class,* which is used .mainly at learning of informatics. One of the effective decisions is "the electronic board". On the computer screen (or by means of projection installation) educational material in the kind of illustrations, fragments of video films, audio spots can be submitted, it can be shown the computer model of any process. We are paying special attention, that computer used as the electronic board should be *multimedia* one, as there is no sense to reproduce on lecture screen only textual material.

The special class-room should be in educational institution; this room should be equipped by video-projector and screen for making the lecture with using the computer, or the computer should be moved from one room to another on special wheel-barrow.

The similar decision is the creation at school the electronic informational culture center (artcenter, electronic gallery) or school electronic library, that is quite possible at such quantity and already quality CD-ROM on separate themes, multimedia encyclopedia, computer albums, guidebooks etc.

4. For the teacher could something prepare something and to show on lesson, *it is necessary to have simple tool (author's) mean.* Better and easier of HyperCard for Mackintosh so far nothing is created. Just HyperCard has been able to break a barrier between the computer and teacher in USA. To HyperCard adjoins HyperStudia, SuperCard etc. In Russia there will be some problems with HyperCard, since in it language, close to natural English, is used for programming, but, alas!, to English, instead of to Russian. So the development of suitable tools for teachers is necessary, in which it will be able to use native language.

5. Basically the electronic textbooks, educational multimedia encyclopedia *should form* not in handicraft conditions by the teachers, but *qualified developers,* uniting humanitarians and representatives of natural sciences. On the basis of these materials the teacher can carry out preparation to particular lesson. In the kind of an example it is possible to show the activity of firm *КОМИНФО* (Moscow), which lets out in 1996 at once eight CD-ROM in Russian: Moscow Kremlin, St.-Petersburg, Petergof, Art encyclopedia of classical foreign art, Dictionary in pictures etc.

6. It is necessary to *explain to the teacher the advantage and lacks of using computers in the educational process.* The usual textbook was and will be necessary as the main «instrument» of the schoolchild. Any text is much more convenient for studying in usual book, instead of on screen of the computer. Electronic textbook frequently supplements usual one, and it is especially effective when:

- provides practically instant feedback,
- helps find quickly the necessary information, search of which in the usual textbook is complicated.
- much saves time at repeated references to hypertext explanations,
- alongside with brief text it shows, tells, simulates etc. (Just here the opportunities and advantages of multimedia-technologies are displayed).

Even when the electronic textbooks or educational encyclopedias are used, expediently to use a hard copy of those sections, which are chosen in these manuals for using by learners.

7. It is necessary to *guarantee each teacher an opportunity of regular increase of qualification with using of new information technologies,* for in practice shows an opportunities and lacks of electronic means. In other words, it is necessary to create for teacher «friendly environment» (computers of a type Mackintosh make a base of it); good software with clear graphic interface; simple tool means, and also to create general atmosphere, aimed at the using of computers in teaching process. It is necessary at the same time to develop of large number multimedia manuals and encyclopedias for using them in the teaching process and as auxiliary means.

PROBLEMS OF THE MULTIMEDIA PRODUCTS CREATION

As it was marked above, textbook, printed text still remain the main manual, but multimedia can essentially help in understanding of a teaching material. Really, "it is better an once to see, than hundred times to hear". It is possible to read the description of some process on tens pages, but noything realize. It is enough to see a short videoplate, and at once all it will become clear. However during preparation of the manual even more, than at work with text, careful selection and structuring of an initial material is necessary. A simple example: practically the whole population daily on some hours looks the TV set, that is audio and video materials, but results (from the point of view of education and cultures) leave to desire best.

We must say, that before the occurrence of multimedia technologies, it was not possible to create high effective'mass computer textbooks, which have much improved process of training. There is the number of good electronic manuals, which is possible and need to be used in educational process, but which have not created a base for the changing of the purposes and methods of education. In connection with the opportunity of uniting in one product textual, audio and video materials the requirements to all initial materials and author's system, chosen for the realization of a product, sharply grow.

At preparation of the electronic textbook or lecture a main figure becomes the expert in contents; he can be rather a teacher, rather a methodist, and expert in the subject area.

Writing of the script, selection and structuring the material represent a separate difficult problem requiring for the decision of a long-duration time. Such expert, connecting in self qualities of the set forth above experts, and also art designer, film producer, rather difficult to find, but just he defines success or losing of work of the whole developer's team.

It is necessary to define a platform, for which multimedia product will be developed. In Russia in sphere of education there are used many types of, computers, but as multimedia computers it is possible to use only senior models of IBM PC - compatible computers or computers of Mackintosh type - that is the best multimedia computers in the world. Unfortunately, in Russia the park of these computers (both types) does not exceed 10-15 % of general number computers used in education, nevertheless just on these computers the bodies of national education should be oriented themselves, planning re-equipment of educational institutions.

This implies that it is reasonable to develop applied products just for two platforms, especially if the developers want to offer their product to other countries (we shall remind, that in USA Mackintosh are used more than in 60 % of schools). On the other hand, it is expediently to use author's stations on base of Mackintosh, which permit to create applied products with smaller expenses of working hours for developers, and also have a wide spectrum of tool means, enabling to fulfil development at once for two platforms (a part of them will be named later).

The experts in informatics should help to choose a suitable tool means and to realize the project. Thus they do not be interested in external computer effects, as it is frequently, and strictly to follow to a general plan of the expert in contents. In turn, the choice of an author's means for realization of scenario is rather complicated. During discussion of the scenario it is necessary to reach reasonable compromise between the author of scenario and programmers.

PREPARATION OF INFORMATION BLOCKS

At the creation of an applied product it is necessary at first to prepare information blocks (text, audio and video information) with maximum quality. For education sphere this is one of most important requirements. It is possible to adduce examples as quickly multimedia encyclopedias, which are widely distributed in the world, fall behind life and sometimes contain the direct errors. Therefore the special attention should be pay to the quality and reliability of the information.

At this stage the requirements to fonts, textual formats are also defined; checking of data and editing should be carried out. Video-shootings or choosing the materials in archives of video-recordings should simultaneously be fulfiled, formats for compression of the video-information should be chosen, speeds of data transfer from multimedia-carrier, the frequency discretezation for audio-information should be determined and also sould be resolved many other technical questions, connected with realization of conceived idea.

DEVELOPMENT OF MULTIMEDIA-PRODUCTS IN CLASS OR LECTURE-ROOM

If we consider, that the skill to present results of our work in printed form is a compulsory element of information culture of the person, then skill to create electronic multimedia products will become the same compulsory element of culture in the nearest future.

The multimedia means permit considerably to enrich the educational process thanks to using of various materials. If there is the opportunity, it is necessary without fail to enter into school subjects the practical lessons on preparation of educational multimedia products. However, thus there is the danger of excessive passion for ready materials to the detriment to creative activity of the schoolchildren and students during lessons. Really, now there are many compact discs (CD-ROM) in the market, containing sound libraries, videoclips and digital illustration. Students are offered to collect the ready products from details. Thus learners as though go from "the live world", from opportunity to record the phonogramme themselves, to make a photo or video report, and then to create their "own" multimedia product or presentation.

It is reasonable to suggest the following scheme. Alongside with lessons with using of multimedia products, learning of means of navigation etc., it is necessary to carry out the practical lessons on development of ready products with using materials prepared by the schoolchildren themselves. For preparation and digitalization of such materials they sould have some addition set: a microphone, scanner, digital camera, videocamera. In class-room it is necessary to use whenever possible simple tool means, enabling to the schoolchildren under the direction of teacher on their own material to create the samples of educational products or multimedia presentations (for example, HyperCard).

Do not forget, that the schoolchildren can frequently invent the original decision (from the point of view of presence of fruitful idea), therefore it is worth while to analyze carefully the ready samples, and then the best from best can be improved by creative groups with the help of more powerful author's means, such as the *Director* or *Author - profy*. This is one of the ways of using variety of multimedia means, which is finished by creation of perfect multimedia product.

The interesting experience of similar lessons has St.-Petersburg State Electrotechnical University. Here author's system HyperMethod (Multimedia Authoring Tool) was developed; with using of this system the teaching process on development multimedia products is carried out.

DISTANCE EDUCATION

All submitted above can be referred also to the problems of development of the distance education. The modern information technologies give all opportunities for creation of this kind of education, just *creation*, instead of replacement of usual post on electronic in correspondence education, though and this step is also approved. Just as with using of multimedia technologies ought to develop new methods of distance training and to carry out intensive preparation of the teachers for the new style of work has become an integral part of teachers' qualification. Accordingly, alongside with the using of multimedia products, the opportunities for carry out the videoconferences, seminars and etc. are appeared. In distance training one of the main elements will be simultaneous work of the students at remote terminals under the direction of teacher (he is frequently named *moderator).*

THE CONCLUSION

In conclusion it is necessary to note, that just the multimedia technologies enable to carry out humanitarization of education through informatization, that on self would be major achivement. The multimedia technologies acquaint the schoolchildren with electronic reproductions of the best works of culture, permit to organize listening of musical compositions etc. Thus the works of art can be used as background in applied programs or to occur during process of decision certain historical or another problem, to become familiar for schoolchildren. Such opportunity is especially important for schools which are remote from cultural centers of country, in the view of travel expenses does not permit to organize appropriate excursions for all schoolchildren.

THE OFFERS TO THE PROJECT OF THE RECOMMENDATIONS OF THE CONGRESS

On the base of submitted material it is possible to make the following offers in project of the Recommendations.

1. To ascertain, that in postindustrial society or information society the purpose of informatization of education should be put for the first place, that is providing of access according to national and religious customs of the given community to any information in any point of the world should be delivered.
2. To recommend to introduce into curricula of pedagogical universities and colleges the preparation on new professions of the teachers: the teacher - methodist (scenaris-maker) on creation and application of teaching multimedia-products, and also to introduce a special subject of information culture, one of the elements of which should be the development of the multimedia-publications for teaching purposes, mastering of navigation rules in information world.
3. To create under UNESCO aegis the regional and national centers of system researches on informatization of secondary school, in which data on researches and applications of informatics means in teaching process should be systematized and generalized.
4. To recommend to state-members the preparation of the state programs on informatization of education. One of the elements of such program should be state support of expensive preparation of electronic multimedia- and Internet-textbooks for each country.
5. To recommend under UNESCO aegis to begin the project *"Electronic Artcentre in School"* (possible versions are *"School Electronic Library", "Electronic gallery", "Information and Cultural Center").*

TEACHER EMPOWERMENT AND TECHNOLOGY

Bengt Bengtsson

EDUCATIONAL CONSULTANT
UNIVERSITY OF GOTHENBURG AND ENATOR AB
(SWEDEN)

Generally it is hard to measure the importance of information technology (IT) in education as IT is only one factor amongst many that affects the learning environment and enhances the cognitive development. Parents, subject area, classmates, culture, teachers are just some of those integrated components that together create the prerequisites of education. Just to foster the ability to read and listen may sometimes be more important than the use of technology in a learning environment. Student can create personal multimedia presentations in their brains when they read or listen. Abstract, relation-free thinking is also an important goal for education.

Mankind has always tried to replace muscle power with machines. I am fascinated by the fact that the less productive work we do with our muscles the bigger they grow. Many people devote themselves to bodybuilding, jogging and physical welfare. As for brain support we did not have a real break-through until the computer arrived. Before that we have had several development steps such as the pen, the printing press, telephones, faxes etc. My ancestors the Vikings used stones to register data on and that was a long-lasting but primitive method for data handling. My hope is that today when computers support both muscle power and brain power we will start brain-building and intellectual jogging in order to enrich our lives and to unload or reduce boring, repetitive, routine tasks.

IT as a technique has developed very rapidly but it is not until the multimedia facilities arrived, that IT has got enough capacity to substantially support the teacher and students. Now we can digitize many impressions from many senses. As technique and experience of IT have succesively developed, IT nowadays supports us not only in routine work but also with simple and advanced decisions, simulations and even offer limited artificial intelligence. IT is ready for education.

IT has gradually changed our society from an industrial to an information and knowledge society. In Sweden about 60 percent of the labor force are information and knowledge workers. This change ought to affect education or should education affect the society? There are many educational theories that support both opinions so we have to consider if we want to define progressivism, essentialism, perennialism, reconstructivism or constructivism as a goal for education.

Anyhow, the changes in society have resulted in new types of jobs, new moral and ethical values, new cultures, new ways to spend our spare time, new terminology, instant access to global multimedia information, data communication, virtual organizations etc. I personally believe that education, at least to a certain extent, ought to prepare students for this partly new infrastructure and environment. Due to these continuous changes, society, the private and the public sector need a new kind of individual, a flexible, critical person with high quality thinking and familiar with the use of information technology. Industry itself has already integrated IT in their business process reengieering activities in order to reach strategic, competitive advantages and adapted its organization, administration, its material and immaterial infrastructure, partly because everyone within an organization now has access to most internal and external information concerning its business activities. Education can learn a lot from this new approach. One example is the use of Total Quality Management (TQM) thinking where everyone involved in a process contributes to make it more effective rather than to criticize the final result. The method offers an interesting new idea for how to look at grading. The process has become more important than the method for measuring the outcome and result. Other relevant methods for the creating of a new learning environment and a new approach to knowledge are the use of methods such as business reengineering processes (BRP) and organizational learning (OL).

The change in society, industry, public sector and the new demands also affect the individual. Education must contribute to offer the individual a rich life in the future, knowledge society. Students must learn to adapt themselves to the new culture, be able to evaluate and criticize information and develop morale and ethics. The school must teach them how to think rather than to reproduce data and to prepare them to be life-long learners and knowledge workers. I believe that education must reach a new ambition level to satisfy these demands. We must leave the data school, where students mainly reproduce data and teach them how to analyze data to get information, synthesize information to get knowledge or applied information and ultimately how to evaluate knowledge to get wisdom.

Teachers mainly have two roles in education. They are administrators and educators. In both activities they handle data, information and knowledge. IT ought to be a very useful support for the fulfillment of these two roles and at the same time make the teachers' life easier, more interesting and maybe even more fun. Just look at typical teachers activities. They collect, store, copy, calculate, check, register, search, rewrite, analyze, present and eliminate data. These activities are tailor-made for computers. IT can unload much "donkey-work" from education and give all parties more time for discussions, social interaction and mastery learning.

Teachers sometimes filter data and information for the students in a classroom environment. Other educational filters are old subject areas, old curricula, not updated textbooks, a restricted classroom environment and passive students. The traditional way of teaching sometimes delivers a very limited amount of information. The teacher mainly chooses the contents and collectively distributes it to the students. Reproductive learning is still favored, especially in different tests. An alternate way of teaching is Problem Based Learning (PBL) where the teacher is more of a coordinator, informator, navigator and facilitator. Students are looked upon as individuals and have direct access to most data and information in a virtual classroom in the global multimedia world. In this kind of learning environment it is essential to teach students how to navigate in the information jungle, how to search, find and analyze data and information in order to achieve quality learning or super learning.

To reach this new goal for education and to create this new learning environment we need IT. We ought not to start to buy and implement hardware and software and after that decide what to do with it. This approach often results in fragmentary solutions, efforts and ideas. Initially we must simply try to identify those new official or institutional activity goals and consider how this ambition will affect the roles for teachers and students. At the same time we must also reflect on the need for a change of the present organization and administration of the school. Changes in the physical infrastructure are also important to consider. The classroom is a very old institution and may need to be modernized. When these ambitions and goals are clarified we must ponder if or how information technology can support us to carry through these activities and reach the desired level of ambition and the new educational goals.

What I have said so far implies that IT may have an important role in the empowerment of teachers and students. For example IT can be used as a personal, administrative tool, as a personal teacher, as a drill-and-practice partner, as a partner in discussions and team-work and as a data collector, It can also assist as an intelligent blackboard and as a link to the outside world via global data-communication.

One special advantage with IT is that all kinds of educational material such as books, pictures, movies, sound, files on disks, educational software, papers and other documents now can be digitized, stored on a CD-

ROM or reached via Internet and be controlled by the computer. In a Multimedia Laboratory (MML) learning environment teachers and students can produce professional teaching material, electronic reports and many other applications for education. At this point I must stress my opinion that IT is not the only road to knowledge. It winds through a learning environment with many different pedagogical methods and various forms of teaching material. It is never a question of either or, rather both and. Information technology can and should never replace the living multimedia person, the teacher, with feelings, body language, enthusiasm and concern. This must be a key principle in education and teacher empowerment. In my country we considered this condition so important that we defined and added some general principles for IT in school:

- IT must be integrated in the curriculum, not an isolated subject area;
- IT must be a tool among other tools;
- Students must be in control of IT not vice versa;
- Education must apply an overall view - Wygotsky;
- Continuous, coordinated research and evaluation are necessary.

Even if the effects of IT in education are hard to measure I believe in what an outstanding researcher said to me "I see something positive happen to the students and that is enough for me." It is also important to understand that education is a complicated, dynamic system with many integrated subsystems. If one component changes it can and will affect many other subsystems and probably the whole system. Therefore if is important for the teacher to adapt a systems approach to IT. The use of IT in school may not only affect internal functions but also parties outside the school, parents, authorities etc.

If IT should become an efficient tool to empower teachers it is important to have this overall, systems approach and to structure, analyze and consider all components in an IT-system and how they interact. A possible start is to identify the use of IT in different educational activities for example in computer competence, vocational training, computer science and IT as a purely pedagogical support. Different activities may need different kinds of hardware, software and teaching methods. When the activities are made clear the teacher must consider and coordinate the resources necessary to perform these activities. Information needed, suitable hardware, various types of software, activity-oriented in-service-training, research and development and realistic budgeting are the most important ones. A function as computer coordinator and other "IT-pilot" functions are necessary to establish in every school.

In an efficient IT learning environment, the choice of hardware is of course essential, as well as systems software and application software. Anyhow it is important to understand that the learning environment in a school consists of many other things like the experience and knowledge built around the system. The library of teaching material, exercises, tests and the organization and administration of the IT-resource are vital components that affect the total quality and effectiveness of the educational IT-system.

I have seen many schools that think that the fragmentary change and updating of hardware will solve many problems and found that it is the contrary, simply because you must to a certain extent rebuild the IT environment. You sometimes have to start from the beginning again and in the process you lose old knowledge.

To make a summary I think that **the new goals** that need IT to be realized are:

- Partly new subject areas;
- A problem - oriented training to become information finders and knowledge workers;
- An individualized education;
- Training in critical thinking and abilities for life-long learning;
- A cross curricular and research-oriented approach with teamwork;
- More active students and new roles for teachers.

The means we need to achieve these new goals are for example:

- A new material and immaterial infrastructure for education;
- New kinds of teaching material and curricula with integrated IT;
- Adaptation of present curricula to IT;
- An activity-oriented training of the teachers in how to "informate";
- A training in data-pedagogy;
- A virtual school environment with IT-resources and distance learning facilities, available to students independent of time and place.

There is an abundance of information technology, available, for example, powerful multimedia computers, complete Multi-Media Laboratory environments, advanced peripherals, such as color scanners, color printers, CD-ROMs, portable computers, digital cameras, digital video cameras, modems for data communication, LAN, MAN and WAN, Internet, compressed video for distance learning, portable phones with datacommunication facilities via Internet, faxes, a multitude of software for most subject areas and activities etc., etc.

For me the most important resource in an educational IT system is the teacher and the in-sevice training of teachers. My experience is that a success factor is to motivate the teachers in for example a course or seminar where you "use new technique to teach about new technique." The idea is to show the teachers the power of IT and enforce them to use this new tool and virtual media in their roles as administrators and educators. Another purpose with this training is to make them aware of the new demands from society, industry and individuals, the need for an overall systems approach when they build the IT-resource and work together to consider all components and changes necessary to establish an effective IT-system for education.

It is crucial to teach teachers how to use IT in their personal administration to make them more professional, produce high-quality teaching material, material for presentation etc. It is essential to place resource computers in the teachers' room. By doing this, the teachers get acquainted with the technology and how to use IT for their own, daily administration of educational and other data. It is important that function comes first, then technology. After this introduction it is easy to teach them how to use IT and various kinds of software as a purely pedagogical tool - data-pedagogy.

One, very important point of view is that whenever a school buys software, it should be followed up by a course or a seminar where teachers from different subject areas (to stress the cross curricular teamwork) discuss how to use it effectively and how to integrate it in the curriculum.

I simply mean that in-service training of teachers must have a high pedagogical value, be motivating and activity-oriented. I saw a phrase somewhere that said. "It is hard to motivate high-tech students in a low-tech environment." For me and many others, education is the most important activity during this decade. The implementation of IT in education will no doubt expand the teachers role and responsibility and make his or her profession to a real career profession. That fact will attract still more qualified persons to work within education and that in turn may make education even more effective and interesting.

A high quality education is crucial for people to be able to live, develop and experience a rich, creative life in the future knowledge and IT society.

Commission II

ENHANCING THE TEACHER'S CREATIVITY BY EXPLORATORY COMPUTER ENVIRONMENTS

Evgenia Sendova
RESEARCHER, INSTITUTE OF MATHEMATICS AND INFORMATICS
BULGARIAN ACADEMY OF SCIENCES

INTRODUCTION

The fear that accompanied the first appearance of the computers in the classrooms that it could replace the teacher was closely connected with the paradigm of the educational process as one of transferring/consuming knowledge. If, on the contrary, we see this process as one of producing *knowledge by the teachers and students alike, such a fear becomes unjustified. For it is not the introduction of the computer to the classroom per se which would change the teaching process for the better but rather how computers are used. Thus if the computers provide an environment where knowledge is being produced the teaching/learning process could become more challenging, demanding, exiting. Furthermore, in an exploratory computer environment, learning can be approached as a task of discovering something rather then learning about it, the reward being the discovery itself. This determines a new paradigm of the teacher ranging from a researcher observing the cognitive development of his students to one who enriches his subject matter as a science and is ready to convey its real spirit to his students.*

On the basis of an educational experiment in Bulgarian schools various strategies for creating classroom culture, in which exploration are supported by suitable computer environments, have been tested and reported.

IT AND THE NEW ROLE OF MATHEMATICS TEACHERS

Three types of competence have been claimed as necessary for the mathematics teachers in order to adequately fulfil their new role in an IT environment - competencies related to mathematics, to informatics and to didactics. The problem is that what is hidden behind *mathematics competence* or *didactic competence* becomes dynamic in the new context. Perfection in teaching mathematics goes far beyond transmitting information of the kind *here is what is known and here is how it is used...* Our experience shows that there are teachers who are well aware of this and tune their teaching style in harmony with the nature of mathematics as a science. Instead of formulating the problems in *prove-that* style, they let their students be creative and formulate as many conjectures as they can about the relationship among elements of a given construction; or encourage them to formulate initial conditions, yielding concrete relationship. Such an attitude makes pupils accept and interpret problems as their own which is crucial from psychological point of view. What we have also observed is that some problems, once achievable only for the potential Olympic champions (in mathematics competitions), are now attacked by future champions... in light athletics. And even if the final results or proofs are not reached by all, at least students have experienced the taste of a mathematical adventure. For the mathematically motivated students, the adventure goes even further - to extend the problem, to generalise the findings, to prove the hypothesis formulated.

To help students become good experimenters and conjectures teachers have to cultivate some important skills and strategies, such as: parametrizing a construction so as to make it convenient for experiments; modifying initial conditions; generalising the problem; studying some particular cases; recognising situations leading to a *dead-end streets.*

Such strategies appear to be even more successful if the teachers themselves take the risk of performing explorations and make the students participants in their discoveries. *We cannot teach the art of the problem solving and problem formulating without engaging ourselves in inquiry* - this is the message of some Bulgarian teachers who have developed classes of interesting mathematical problems that are new to the existing curriculum. With capable and motivated teachers (even if they are few at the beginning), supported by appropriate computer environments, it is possible to help students join and share the joy of the discovery.

BINOMIAL OF CREATIVITY IN IT CONTEXT

The principle of integration was leading in the Bulgarian educational experiment of introducing IT in a radically changed curriculum. It has been achieved not only by integrating informatics with other school subjects but also through co-cperation between teachers of different subjects. An interesting partnership was established between teachers in informatics on the one hand, and primary teachers, teachers of music, natural languages and fine arts, on the other. The idea of *learning-through-exploration* dominated the way we encouraged teachers to work with their pupils. The computer was presented as an environment providing a rich collection of tools to play with ideas not only in mathematical context, e.g.:

- in physics - modelling certain phenomena and processes and playing with the parameters involved;
- in music - formulating certain rules in order to let the computer *extract the order out of chaos* and by experimenting with tempo, rhythm and tonality;
- in languages - inventing patterns in different natural languages and then generating text with specific structure;
- in fine arts - visual modelling in order to analyse and then imitate work of avant-garde artists. Working in a team with the informatics teachers enabled teachers in languages, physics and art to feel comfortable in a computer environment and to enjoy performing explorations in the spirit of their subject.

CONCLUSION

Although good examples of teachers' creativity are not found in every school our endeavour is to spread their achievements through journals and conferences for teachers, and based on them to enrich the in-service and pre-service teacher training. If we hope for a real change in teacher education, we should bring today's and tomorrow's teachers in situations in which they would stop thinking about the future in terms of exams or teaching pupils. We should rather enable them experience what they are doing as *intellectually exciting and joyful in its own right.*

INTERNET-BASED INSERVICE TEACHER TRAINING IN MONTANA

David A. Thomas

CO-DIRECTOR AND CO-INVESTIGATOR
NETWORK MONTANA PROJECT
DEPARTMENT OF MATHEMATICAL SCIENCES
MONTANA STATE UNIVERSITY (USA)

INTRODUCTION

In a global economy, expertise, information and capital are essential to the success of any business venture. Corporations lacking the necessary expertise and information at every level of their organization cannot compete. Nations lacking competitive corporations cannot grow economically. At the same time, meaningful public debate on the environment, natural resources, community and economic development, health care, and education cannot take place in an electorate incapable of understanding the issues. More than ever, nations need mathematically and scientifically literate and technologically competent citizens.

At the Thirteenth International Conference on Technology and Education held 17-20 March 1996 in New Orleans, Sir John Daniel of the Open University stated that the demand for higher education in the third world is growing so rapidly that creating a medium sized university every week would not meet the need. The demand for universal access to higher education is a global phenomenon. As a result, governments around the world are struggling to develop effective, scaleable, affordable alternative to conventional, high-cost educational delivery systems. Governments and the private sector are investing considerable time, energy, and money in the development of computer networks and New Information Technologies (NITs) as the basis for a new educational delivery system accessible to all citizens wherever they live.

This paper reports on two projects currently providing Internet-based teacher inservice training in the State of Montana, USA.

THE NATIONAL TEACHERS ENHANCEMENT NETWORK PROJECT (NTEN)

The Burns Telecommunications Center at Montana State University (MSU) (http://www.montana.edu/wwwxs/btc.html) is a laboratory for creating a more accessible and effective university for the 21st century. It seeks solutions to several of the critical challenges facing public higher education. These challenges include:

- Increasing public access to lifelong learning, especially for isolated individuals and communities.
- Enhancing teaching and learning.
- Keeping instruction affordable.
- Expanding partnerships between universities and public/private organizations.

The National Teachers Enhancement Network Project of the Burns Telecommunications Center offers graduate-credit science and mathematics courses to teachers nationally. Teachers are able to participate in the telecomputing courses from convenient home or work locations by dial-up modem connections or Internet access. The Network provides teachers with high qualify graduate science courses taught by university scientists, engineers, and mathematicians. It also enhances professional networking nationwide between science teachers and active research scientists.

The courses are developed by teams of scientists, high-school teachers, and science educators. The teams work closely to identify appropriate content and tested classroom activities for each course. Course topics are selected based on input from science teachers, identified needs from national surveys and reports, and current events taking place in science and technology. Courses are team-taught by the university faculty and an active science teacher.

The NTEN course Visualization and Communication Tools for Mathematics and Science Teaching (http://www.montana.edu/~wwwxs/netscape/mathvis.html) was developed by the author as a means for inservicing K-12 teachers on the use of graphics-based modeling and data analysis tools. The course syllabus includes the following topics:

- Measuring Global Sea Surface Temperatures Using NIH Image
- Measuring Mars: A Visit to Olympus Mons Using NIH Image
- Exploring Phytoplankton Pigment Concentrations Using NIH Image
- Review NASA's SIR-C Educational CD-ROM
- Explore Euclidean and Non-Euclidean Geometries
- Explore Euclidean Geometry with the Geometers Sketchpad
- Explore Hyperbolic Geometry with Non-Euclid.

Texts used in the course are:

Wolf, R.S. & Yaeger, L *Visualization of Natural Phenomena*. New York: Springer-Verlag, 1993.

Thomas, D. (Ed.) *Scientific Visualization in Mathematics and Science Teaching*. Charlottesville, VA: Association for the Advancement of Computing in Education, 1995.

Participants receive a box in the mail containing the course syllabus and texts, CD-ROMs, computer disks, and other materials. Class discussions occur in an electronic conferencing tool accessed via dial-up modem or the Internet. Assignments and other communications are handled via e-mail.

Sixty-one participants enrolled in this course during the summer of 1995. To assist with the resulting avalanche of e-mail and to facilitate the use of the electronic conferencing tool, three teachers who had previously taken the course served as assistant instructors. Their participation greatly enriched the scope of the discussions and resulted in a high degree of participant satisfaction.

This approach, combining extensive mailings with low bandwidth communications, represents one solution to a problem faced by many rural teachers, limited access to high bandwidth technologies. Of course, once teachers experience the use of a fast TCP/IP connection, they are eager to acquire it on a regular basis for both professional and personal use.

THE NETWORK MONTANA PROJECT

In October of 1995, the National Infrastructure for Education (NIE) program of the National Science Foundation (NSF) funded the Network Montana Project (RED-9554251) (http://www.math.montana.edu/dave/nmp/home.html). The partners in Network Montana include teachers, administrators, and researchers from the state's educational system, leaders in state government, and individuals from a variety of community, professional, and private sector organizations. Commitments of talent and resources from all partners are focused on the development of a lasting infrastructure capable of supporting the development of a variety of educational telecommunications services. The Network Montana Project will

- Build and maintain a state-wide coalition of partners from academia, government, and the private sector responsible for directing a wide variety of K-14 educational networking activities during the period of NSF/NIE funding and in subsequent projects;
- Support and enhance a number of nationally significant systemic mathematics and science education reform projects underway in Montana;
- Develop multimedia network-based materials and delivery systems integrating mathematics, science and technology to enhance access and usability of many scientific resources;
- investigate adaptations of educational and informational telecommunications required to serve populations with special needs including those that may be visually or hearing impaired; and
- Develop a workable, rural, community networking model that promotes teleliteracy for rural citizens to enhance their involvement with lifelong learning, entrepreneurship and local/state governance.

As Co-Director of the Network Montana Project for materials development and teacher training, the author and collaborating K-12 teachers are creating on-line materials that integrate mathematics, science, and technology in the context of contemporary scientific issues and problems. These materials demonstrate the use of a variety of graphics display and analysis tools, including NIH Image. Netscape Navigator acts as the interface to the classroom activities, scientific data sets, and other resources. As these materials are developed, distance learning courses will be created to train teachers in their use. These courses will be offered through the Burns Telecommunications Center to teachers around the world.

During the 1996 -1997 school year, a set of classroom activities on the theme Earth System Science has been developed. These materials will be published on the World Wide Web (WWW) in August or September. The following excerpt from the Storm Tracker Activity illustrates Network Montana's use of powerful WWW information and computational resources to motivate and support scientific investigations.

STORM TRACKER ACTIVITY

Objective

In this activity, students continue their study of the science of meteorology and extend their use of the image processing tool NIH Image.

Focus

Hurricane Andrew - Costliest Natural Disaster in US History.

Using NIH Image to Make Measurements

Start NIH Image. When the program has stopped loading, pull down the File menu and select Open. When the dialog box appears, double-click on the image aug24. Use the hand tool from the Tools Window to slide the image up until the hurricane is visible.

1. What geographic features do you recognize?
2. What land forms are obscured by clouds?

Select the magnifying glass from the Tools Window and click repeatedly on the image. Eventually, the small squares that comprise the image will become visible. Each of these picture elements, or pixels, represents some portion of the Earth's surface. Because the surface of the Earth is curved, not all pixels represent the same area on the ground. As a result, precise measurements based on such images involve complex mathematical and scientific factors beyond the scope of this lesson. On the other hand, reasonable estimates can be made using NIH Image and a few WWW information resources.

- First, decide what is you are going to measure, in this case the diameter of the hurricane.
- Second, obtain an estimate of the average pixel size along the measuring line. Select the line segment icon in the Tools Window and draw a segment between the tip of the Yucatan Peninsula and Washington, DC on the image.

How Far Is It? computes the shortest distance between any two points on the surface of the Earth, in this case the ends of your line segment. Using the Xerox PARC Map Viewer option, zoom in on the Yucatan to obtain the longitude and latitude of the southernmost end of the line, 21.75N 87.34W.

The same procedure yields the longitude and latitude of Washington, DC, 30.44N 82.02W.

When these coordinates are entered in the How Far is it? (see "Screen").

Screen:

From: 38:53:42N 77:02:12W
to: 21.75N 8734W (optional)

[Look it up] or [clear]

– the distance is obtained.

Distance between 38.88333N 77.0333W and 21.75000N 87.34000W, as the crow files:

1329 miles (2139 km)

Initial heading from 38.8833N 77.0333W to 21.75000N 87.34000W: south-southvest (2103 degrees)

Initial heading from 21.75000N 87.34000W to 38.8833N 77.0333W: north-northeast (25.1 degrees)

Returning to NIH Image, pull down the Analyze menu and select Set Scale. Enter the Known Distance of 1329 miles after selecting Miles as your Unit of length.

- Third, measure the diameter of the hurricane by drawing a segment of the desired length and location, pulling down the Analyze menu and selecting first Measure then Show Results.
- What is the diameter of the area affected by the hurricane, not just the central part of the storm?

1. Select the freehand icon in the Tools Window and circle the strongest part of the hurricane.
2. What is the perimeter of that part of the storm? The area?
3. How does this area compare to the area of the state in which you live?

Informal field trials with these and other Network Montana Project materials among both "normal" and "special needs" student populations have shown that students respond enthusiastically to the integration of mathematics, science, and technology in meaningful contexts using highly interactive graphics interfaces. As these and similar materials developed by other educators are packaged in courses for teachers and offered to learners of all ages, governments and private sector partners may come to see the value in creating and sustaining high bandwidth educational delivery systems.

ACKNOWLEDGMENT

The author wishes to thank NTEN and Kirn Obbink, George Tuthill, Gerry Wheeler, and Chris Vogeli for permission to reproduce portions of the on-line Burns-Telecommunications Center and NTEN documentation in this paper.

DEVELOPMENT OF "MULTIMEDIA" TEACHING AND LEARNING ENVIRONMENTS: AN ACADEMIC ADMINISTRATOR'S VIEW

A. Y. Montgomery
HEAD, DEPARTMENT OF COMPUTER SCIENCE
ROYAL MELBOURNE INSTITUTE OF TECHNOLOGY (AUSTRALIA)

ABSTRACT

Application of multi-media teaching and learning materials in educational and training institutions - whether addressing primary-through-tertiary or whole-of-life continuing professional education - brings two main categories of problem: technical researching and pedagogic.

Major pedagogic issues include forming a dear understanding of how to harness the strengths and minimise the weaknesses of the new technologies, and how to enable a smooth transition by teacher and learner from traditional modes of knowledge and skill acquisition to ones invoking the "open and flexible learning" paradigms. Prime amongst the technical researching issues are the development of trained staff and the acquisition and maintenance of cost-effective environments for production and dissemination of material.

Although these issues may appear multi-dimensional, rapidly-changing and daunting to those confronting them anew, they are basically old problems in a new guise. In Strategic Analysis and Planning lie the solutions.

Strategic Analysis of the pedagogic objectives of the organisation, of the results of carefully conducted and confirmed experiments and of the verified costs, benefits and capabilities of the technologies to meet clearly-defined objectives, is the essential first step. Strategic Planning to facilitate the acquisition of the resources to meet the objectives identified and to monitor and control the implementation process so as to overcome the risk situations which will inevitably emerge, must then be invoked.

The move to multi-media, like the move to effectively adopt any new teaching and learning methodology, can only be successful if it is undertaken as part of a coherent long-term plan designed to provide solutions in a system-wide manner. Any other approach is simply not viable.

INTRODUCTION: AN ACADEMIC ADMINISTRATOR'S APPROACH

An economic rationalist approach to the application of new technology in education demands demonstrable excess of benefit over cost. The paper discusses some factors relevant to analysis and planning processes which seek to ensure this outcome for students, teachers and academic administrators. The recommended process takes a long-term perspective, commencing with Strategic Analysis of objectives and key success factors and moving to Strategic Planning for implementation.

STRATEGIC ANALYSIS

Strategic Analysis is based upon the conventional S-W-O-T evaluation: Strengths, Weaknesses, Opportunities and Threats. This analysis is a useful-precursor to any proposed new individual, organisational or national endeavour, for defining long-term Vision, Mission and Objectives, as well as the Criteria for measuring achievement of the Objectives.

Details of approaches to such analyses as they relate to Informatics application may be found in Montgomery (1994) and associated references.

Strategic analysis assists in identifying key success factors to be incorporated and key issues to be resolved in the design of a solution to reach the defined objectives.

The following sections canvass some key factors and issues that are important to the effective and efficient application of Informatics in Education in Australia today.

IDENTIFICATION OF ISSUES

Over the years there have been many attempts to implement both CML and CAI in Australian Universities. (See, for example, Bruhn et al., 1988). In these endeavours - some successful, many less so - several MAJOR groups of success factor and issue have been in evidence, and may be broadly categorised into those relating to Staff and Equipment Development, those relating to Pedagogical Factors and those having overall Economic Impact. Most of the previously identified factors are equally relevant to the inclusion of Multi-Media technologies in the delivery and support of teaching and learning.

Needless to say, these factors are inextricably inter-twined. Understanding which combinations of which factors lead to success will only emerge when coherent reports of carefully conducted studies are widely available.

STAFF DEVELOPMENT

I. The Current Academic Culture

Most Australian University staff regularly use overhead projection material in their presentations and provide, in advance, copies of their notes for student use in class, and they recognise the benefits to themselves and students from doing so. However, I believe, most would prefer to attend a room with a white board or a black board and write out all material "de novo" whilst presenting their lectures, rather than have the problems with learning about, using and overcoming the acquisition and operational problems with "high-technology" teaching & learning equipment and with a shift of their Teaching and Learning roles.

The success of Australian tertiary education in the past has largely been achieved by the individual efforts of a number of talented researchers and teachers. The move to Multi-Media, just as those to CML and CAI, requires (at least the following) several cultural shifts for the academic: from presenter (powerful/leadership role) to facilitator (subservient/mentor role), from individualist (technical specialist) to team player (one of many specialists), from flexible/responsive/independent person to constrained/structured/dependent person, and from curriculum designer to curriculum follower. It is very clear that many Australian academics don't like these shifts!

In the following some of these issues are amplified.

2. Skills Inventory

Academics ask themselves "Do I have the skills necessary to construct good quality CML, CAI, Multi-Media etc. lessons myself, or is a complete team of specialists required? Do I, as the subject area expert only, want to play second fiddle to all these other contributors? And if a whole team is required, how easy is it to obtain access to that team for my subject/course?"

In many Universities, this latter step involves long delays and considerable frustration in obtaining the budgetary allocation and in securing the production team.

3. Motivation

Do I actually WANT to put my lessons "in a can" and have them delivered automatically, or is presenting to students the activity I actually enjoy most, out of all my academic roles?

In the current academic environment, how can I justify to myself investment of time in the creation of computer-based material? If I am not to be rewarded for the extra effort in learning about and using these technologies, why should I bother?

Furthermore, it is not clear which combinations of which modes are definitely effective and efficient for staff and acceptable to students. And the relevant facilities are either not available or not adequately maintained for me to use without extra effort. I do not have the time and energy to be a pioneer in this area, and therefore will not do so.

If and when all these matters are resolved so as to make them painlessly unable by me, then perhaps I will. In the mean time, I will use my traditional methods.

4. Staff Training

Can I afford the time to be trained in this new technology and to use it? In most Australian educational institutions, teaching/academic staff members view themselves as being "over-worked and under-paid". Any request for them to undertake training or activities extra to their current burden is viewed as being vexatious and stressful. Requiring staff to gain Informatics skills, even though such skills might improve their working efficiency or effectiveness, is seen by some as a great imposition.

A first step out of this impasse is to provide every staff member with the technology which is to be mastered. Next, courses have to be provided to commence skill building towards the new technology. Such courses need to be available at times and places, and under conditions which encourage all relevant staff members to attend.

No matter which method is invoked, the process of changing the culture and the skills of all staff to address the new technologies will take MUCH longer and MUCH more effort by administrators than originally envisaged!

5. Equipment Availability

Next, what arrangements exist to make the use of the equipment by staff easy and trouble free? Does the staff member have to (a) specially book the use of the venue for a particular class (b) carry the equipment to the class room and (c) set it up ready for use, returning it to some central point when use is finished?

What arrangements are made to ensure that the equipment is fully operational when the staff member arrives to develop new material and when class are convened to use such equipment?

And is that equipment adequately configured - with sufficient processor power, disk space per user, security and privacy facilities, main memory, communication bandwidth etc. - to execute the software required, with reasonable response time and without extra effort by the staff member?

If these "hygiene" matters are not addressed, for both the teacher and the student, effective and efficient use of the technology may never eventuate.

ECONOMIC IMPACT

For the academic administrator economic impact is critically important. In this matter there is a fair degree of assistance available in the literature. (See Montgomery, 1989 et. seq.). Cost/benefit can be considered in three parts:

First, what capital and recurrent expenditures need to be made to support this technology? Next, and close-coupled, what are the costs and benefits of this Informatics technology compared with that used currently? Finally, having justified the acquisition of this equipment economically, from whence are the funds to purchase and to support the recurrent expenditure which attaches to it, to be found?

6. How Much?

Careful analysis and planning needs to be invoked to identify the **whole-of-life** costs of all direct and consequential costs which attach to Informatics use for Teaching and Learning.

7. Is the Informatics Option Cost-Effective?

Evaluation of the whole-of-life costs of an initiative is difficult. The process for accurately predicting the benefits is more so.

For any given mode of teaching and learning, the assessment of the relative costs and benefits of the proposed Informatics-supported mode and the traditional style is a complex matter. See for example, Montgomery (1989), Montgomery & Beck (1995) and Marshall et al (1994). Important conclusions from such work include:

"Keep increasing investment in Technology (both capital & human time) until the incremental cost of introducing innovation is the same as the TOTAL COST OF DELIVERY TO ALL STUDENTS FOR THE PERIOD OF THE COURSE, CURRENTLY".

This conclusion gives a strong incentive for the use of technology for learning support which can be shown to improve the success rate of students. And,

"The more the price of a technology is subject to future reduction, the more urgent it may be to invest immediately" (Eden &Ronen, 1993).

Whereas technologies such as CML are categorically cost-effective for delivery of drill & practice exercises, those such as CAI have such a wide range of cost, depending upon the intended outcomes and the development tools available, that accurate cost/benefit evaluation is extremely difficult. Again the cited references give insight into - some of the major factors which affect this issue.

Clearly, the estimation of the cost of production of Multi-Media material has further dimensions of uncertainty, but cost more per hour of courseware than the foregoing technologies at this time when the tools for development of such material remain expensive and difficult to use.

The cost of professional-like M-M course materials will rival that of full Television Production and require a complete professional team with a range of technical, directing and story writing skills which are not conventionally available in most teaching and learning organisations and most certainly, if available, not readily available to teaching staff.

PEDAGOGIC ISSUES

Which modes of delivery using which type of Informatics support are effective in motivating students to learn effectively or better? We don't know. To find answers to this question we at RMIT probably are conducting experiments that have been previously performed at many other places but we are either not aware of them or are not certain that their results are relevant to our situation: so we do them again. What follow is a number of activities conducted at RMIT which have been perceived to perform well, or badly. Unfortunately, these activities also have not been carried out in a sound experimental mariner and so only add to our store of anecdotal knowledge.

What is needed is a catalogue of carefully conducted experiments which can be used as a proper starting basis for planning by academic administrators.

8. Video Delivery of Laboratory Class Instruction

We do know that some very simple applications of Informatics in the class room are extremely cost-effective and efficient and well accepted by students.

For example, at RMIT in the Department of Communications and Electronic Engineering, a video camera is used to record - for the first group of students - advice on how to make effective use of the laboratories and how to conduct certain projects/experiments. For most practical, there is only one set of equipment which has to be used by up to twenty groups. Groups after the first simply view the video before commencing their work, thus freeing staff to provide individual advice, as required.

9. Learning at a Distance

In the Department of Computer Science experiments are being conducted at this time to ascertain satisfactory mode(s) of presentation for extensive, complex, leading-edge, technical material at a distance. At this point the options being considered include:

straight lecture, video-taped and replayed remotely later, either for individual viewing or in a group, with or without a moderator; and

conventional lecture viewed simultaneously by local and remote groups with interaction and instant feedback/response from the presenter available to both groups, the lecture being recorded on video disk and available for replay in the home or work place.

It should be noted that the audio technology we have is not yet adequate for this latter mode because of the difficulty of making audio input available to all participants and then balancing the reverberation times of the auditorium and the communication loop transit times.

10. Discovery Style Learning and the World Wide Web

Can a "Discovery" style of learning assist the acquisition of a complex knowledge base such as that required for understanding introductory Artificial Intelligence concepts, and can such learning be adequately supported using the standard capabilities of the World Wide Web?

An experiment is in train to develop a course to be made available on the World Wide Web which teaches basic AI through discovery learning.

A number of complex multi-part problems is being posed which require the application of several sets of concepts for their solution. The intention is that the core material will be made available on the Web, not specifically linked to the problems set. The students will "Surf the Web" to discover what concept units are available, read sufficient of them to ascertain their relevance and if so, study in more depth so as to apply those concepts to the problem. The core material is still being stored: no results will be available from these experiments until the end of first semester (July) 1997.

11. INEFFECTUAL DELIVERY MODES

Modes of use of Informatics for Teaching and Learning support which are viewed very unfavourably by students include those where whole (10-13 lectures of 50+ minutes) lecture courses have been recorded on video-tape and are replayed, in single lecture sessions, to groups of students, with or without a local content expert/lecturer moderating the replay. Negative reactions are still evoked when the local moderator includes occasional stops in the replay to have discussion. Particularly when the video is of a distant class interacting with a lecturer, our video-viewing-students found the process almost unbearable. Subsequently, the acceptability of the courses when — re-designed and presented by local staff - not as prestigious as the original taped personalities - rose markedly.

Also of note was that, in this latter mode, even though the original video tapes, traversing the same curriculum, were made available for individual viewing in a (reasonably) convenient manner through the library audio-video service, out of several classes of 20-30 students, only one or two students borrowed the tapes and viewed them, and then for only specific ones out of the whole set.

Poor as we know the learning effectiveness of lectures is, the culture attaching to attending lectures and hearing the interplay between fellow students and the lecturer appears to be much better accepted than most applications of Informatics which simply "can" the lecture and replay it. From my experience, only nearly professional (and therefore the most expensive) teaching and learning material of a video kind appears to be accepted as an alternative to most human presenters.

In recent times, there has been a rush amongst my most technology-literate colleagues to place details of the Department's courses and subjects to make them globally accessible over the World Wide Web. Initially included in this material were complete subject guides with details such as detailed behavioural objectives, daily lesson plans, book. lists, practical assignments and the like.

The initial flush of enthusiasm has now been tempered with the realisation that material, unless controlled, can be copied freely by Web Surfers and used so as to compete with the originator. We await the time when data can be exchanged and transactions of small monetary value can be conducted across the Web cost effectively and securely.

Each of the aspects of equipment development has a profound impact upon the whole-of-life costs and benefits of the application of Informatics in supporting Teaching and Learning. Important amongst these are specification, acquisition, installation, acceptance testing, operation, maintenance and de-commissioning. In the following some brief comments are offered for some of these aspects.

12. Acquisition

Deciding which particular versions of hardware and software to purchase for the staff and students in the department should only be undertaken following a strategic analysis of the long- to medium-term directions of the teaching and learning programs of the organization. Long term needs should receive higher priority than short term wants. Uses of technology which are likely to be ephemeral should be avoided. Deciding which technologies are here to stay and which to move on can only be achieved by careful technology analysis and prediction.

13. Whole-of-Life Costs

Coupled to the strategic evaluation must be a survey of the current and emerging technology which is or will become available to address the identified long-term needs. Whole-of-life cost/benefit or cost/value analyses need to be applied to evaluate the optional solutions to the defined and prioritised objectives.

Whole-of-life costs - which include at least those components listed in the introduction above - need to be used as the basis of decision-making, assuming a life-time of 3-4 years (Rettig, 1992). Plans for high technology equipment environments should assume that either physical or technological obsolescence will render equipment not usable - for reasons of either effectiveness or efficiency - after that period.

14. Infrastructural Costs

Installation and maintenance costs can be significantly higher in some countries, cities and buildings than in others. For example, are there fully-reliable power and telephone systems, or are stand-by power generators, power system filters or Uninterruptible Power Supplies required, as well as the normal power reticulation outlets and switchboards? Is a complete halogen flooding system essential for fire control because the building is prone to fire or inadequately serviced by fully-trained fire officers, or both of these?

Is the environmental control found in normal office space adequate to sustain the correct humidity and temperature when all the required equipment is operating in the middle of summer and winter, or is a special unit required? Is sufficient space allocated to house all of the systems support, operational and maintenance staff, as well as any environmentally sensitive storage media, if all of these are required to be proximate to the computer room? Is cabling of adequate bandwidth installed or installable in the building intended to house the equipment? Can a maintenance service offering the desired response time be obtained from a third party or must that capability be developed and provided in-house? If the latter is the case, has provision been made for the acquisition of appropriate maintenance staff, for their test equipment and technical tools, and for space to house these several resources?

15. Maintenance Costs

The cost of maintenance needs to be cognisant of issues such as disaster recovery; security and privacy, back-up, on-going systems staff training and the like, as well as the formal cost of provision of on-call or on-site maintenance which typically costs around 5 % of the capital cost of the hardware per annum, or up to 10 % in the case of specialist hardware or software. And in some countries, operator and maintenance staff, as with all other support staff have to be "home grown" from raw new graduates. Has the budget been cast so as to reflect these cost realities?

These equipment development issues are not trivial matters, but they are factors very frequently overlooked in the evaluation of the costs and benefits of the proposal to invoke Informatics in the educational program and if overlooked can be major causes of unsuccessful projects.

STRATEGIC PLANS

Strategic Plans relate, primarily, to major new initiatives or changes of direction which will be implemented in the long term.

Accompanying these plans, there need to be tactical (medium term) and operational (short term) plans. These latter are useful, if for no other reason, than to assist in ensuring the planner that simple and achievable steps can be taken which will lead in the desired long-term direction. As well as assisting the planner, such plans allow others to understand more of the implications of the strategic initiative.

Furthermore, if it be accepted that success will only come by a gradual build up of knowledge and physical resources and that these will require the acquisition and disbursement of considerable funds over a long period, then a series of medium term plans is essential. Progress should be made step-by-step through a documented sequence of risk-limited and carefully evaluated implementations or pilot-projects.

Only if each such project is successful, should the next step be taken towards the defined long-term objective. Note that this mode of implementation is at variance with the approach taken in many Educational Experiments which have been driven more by polemical and unsubstantiated conviction than by logically and careful controlled experiment and evaluation.

CONFERENCE OUTCOMES

One useful outcome for this conference would be to poll delegates to contribute project details to form part of a carefully referenced list of successful and unsuccessful experiments and ongoing applications of Informatics for Teaching and Learning. Included in this list would be some of the details such as those outlined in Appendix 1 to this paper together with economic data such as those in Montgomery, 1989. Further thought would need to be given to identifying the other parameters which need to be recorded to have a useable set of data to support decision-making.

Acknowledgements

I am indebted to my colleague John Bell, RMIT Department of Computer Science, for his stimulating discussion of the issues raised in this paper.

I wish to record my thanks to the Department of Computer Science and the Faculty of Applied Science, Royal Melbourne Institute of Technology, for support in preparing and presenting this paper.

Disclaimer

The opinions expressed in this paper are mine alone and do not represent the official view of RMIT, or of any Australian Government or UNESCO agency, nor that of any other organisation of which I am a member or to which I refer.

APPENDIX I.I:

Staff, Equipment and Pedagogic Factors Relating to Four Delivery "Technologies"

STAFF DEVELOPMENT/ MOTIVATION	Human Teacher	CML	CAI	Multi-Media Courseware
Subject Specialist REQUIRED?	10 A Subject Specialist is Mandatory	As for Human	As for Human	As for Human
New Knowledge, Skills & Attitudes beyond those of subject specialist required by Academic staff members?	0 A teaching diploma is highly desirable	3 As for Human plus formal pedagogic skills essential	7 As for CML Plus "Film Production" type skills	10++ As for CAI + additional skills relating to MM production
Current Employment & Promotion Environment Motivates Staff to apply this technology effectively?	Yes, Promotion depends upon . being a subject specialist	Some Universities give recognition to excellent teaching	Small compared with effort required	Possibly, whilst use is seen as innovative?
Assists Staff Member to Further Research?	With Teaching Finished, Research can commence	Can support research by freeing time spent in assessment & providing remedial assistance to the most needy	Investment of Time to produce high-quality CAI Reduces Research Output (unless instruction relates to Education)	Time required to produce this material in acceptable quality with existing tools greatly hampers Research
Impact Upon Ideal 1 Mentor: 1 Student Relationship	Supports, if funded appropriately	Antithetic	As for CML	As for CAI
Motivational Environment	Familiar • Individual Expert • Presenter • Power Role • Responsive/Ad-Hoc • Independent • Curriculum Designer	Uncomfortable	More Uncomfortable	Yet More Uncomfortable
		•Team Contributor •Facilitator •Subservient Role •Planning/ Measured •Dependent • Curriculum Follower or Collaborator		
			As for CML ++	As for CAI ++

APPENDIX I.2:

Staff, Equipment and Pedagogic Factors Relating to Four Delivery "Technologies"

CURRICULUM DEVELOPMENT/ PEDAGOGIC STYLE	Human Teacher	CML	CAI	Multi-Media
Responsive to Interactive Ad-hoc questions from Students?	10	0	1?	2?
Patient in Explaining?	2-6	6+ Graded levels of detail, finally providing the correct responses if incorrectly answered	3+	4 +?with "Intelligent Tutor" – type technology
Can Flexibly Adopt Pedagogic Style to suit subject material and students?	10 Top-Down, Bottom-Up, Middle Out, Discovery etc. Depending Upon Material & Learning Style of Student	0 Mostly Bottom-Up/"Drill & Practice"	1 Top-Down & Bottom-Up are Common Modes. Simulation is available & and useful for dangerous etc. environments	Potentially 6-8 All foregoing modes available PLUS MIDDLE OUT Plus Discovery mode is more feasible than for CML or CAL

Provide rapid feedback to small but detailed questions for large numbers of student?	4	10	Not major objective of CAI.	Potentially high, if a CML-style component exists
Effective for Large Number of Students?	10, for small class size 0, class size large	6-10 depending upon acceptance by student	6-10 depending upon acceptance	8-10, if material is of high standard
Efficient for Large Number of Students?	0	10	6-10 if the equipment environment supports large numbers	6-10, as for CAI
Providing the benefit of Group Interaction and Problem-Solving	10 Can facilitate such activities	0	I?	5?? Future ?? Potential for Group-Ware & Group Interaction
Providing one-on-one tutorial support?	1 for large classes 10 for small	5 Having discovered struggling students, can target them for support	As for CML, if the material has an assessment component	As for CML, if the material has an assessment component
Access to Globally-Soured, Well-Structured and Up-to-Date Data, Information and Knowledge, at both broad and deep levels?	4-10	2 Not dynamic	4 Not dynamic	Potential is great. However, the current chaotic lack of structure is debilitating
Assessment criteria ensure that use of system is essential for student success?	Yes Essential	Yes Definitely	Yes As for CML	As for CML/ CAI

APPENDIX 1.3:

Staff, Equipment and Pedagogic Factors Relating to Four Delivery "Technologies"

EQUIPMENT DEVELOPMENT	Human Teacher	CML	CAI	Multi-Media
Equipment Required	Standards Black/White Boards + Overhead Projector	Standard + Monochrome Hardware + Software. Around $2000 per station extra	As for CML with more expensive Software and Colour Display Around $2500 per station extra	As for CML + cost of CD ROM or Video Disk Player + Internet Connect + Larger Processor Around $3500 per station extra
Infrastructure Required?	Standard	Standard + Reliable (or conditioned) Electrical Supply + Purpose-Built (Security/ Heating/ Lighting/ Ergonomics) Space	As for CML	As for CML + Reliable & High Bandwidth Connection to Internet + Dial-Up Facilities for Students & Staff at Home/Factory
Maintenance Expediture and Maintenance Staff Required	Standard	Standard + Reliable (or conditioned) Electrical Supply + Electronic Equipment & Software Maintenance + Housing for all relevant staff and equipment	AsforCML	As for CML but allowing for more complex Hardware & Software Environments
Skills in Obtaining Funds,	Standard	Significant New	Significant New	Significant New

Specifying, Acquirinq, Installinq, Operating and Maintaining Equipment, and Training Staff for Effective Use		Skills for Teachers or Additional Staff	Skills for Teachers or Additional Staff	Skills for Teachers or Additional Staff
Technology Stable & Capable of Long-Term Extension	Yes Subject experts will be required, if only to codify, categorise and catalogue knowledge, but also as curriculum definers, motivators & discussion leaders	Yes Applicability of this technology appears to be relevant in the very long term	Dynamic BUT definitely becoming more accessible	Very Dynamic, BUT the bandwidth bottleneck will DOMINATE for foreseeable future
Subject to Resource Bottlenecks when used intensively	Yes!	No Extremely Efficient if Operational Mode is Correctly Chosen	Yes Each person requires lengthy periods of use	As for CAI + network BOTTLENECKS are frequent AND INCREASING

APPENDIX 2:

Estimating Whole-of-Life Costs and Benefits

FACTOR	WHOLE-OF-LIFE COSTS	WHOLE-OF-LIFE BENEFITS
OVERALL COST-BENEFIT	See detailed cost models for each technology which generally give excellent guidance for the development and delivery cost components but all other cost factors MUST be identified and included	Details of Cost Reduction and Learning Improvement for Learners with differing preferred Learning Styles for each Teaching/ Learning Mode and for each Technology are not yet well evaluated, documented and verified
STAFF DEVELOPMENT	Staff Development is considerable for New Technologies. Such Development incudes, at least: •Technology Familiarisation •New Pedagogic Skills •Major Motivational Challenges, including those arising from role changes: Independent – Dependent Presenter - Facilitator; Flexible: Planned Unquestioned - Subject Expert - Team Collaborator Personal; Power Role: Subservient / Mentor Role; Curriculum Designer: Curriculum Follower	
CURRICULUM DEVELOPMENT	Still require Subject Expert but: •The Required Shift from Ad-Hoc/ Flexible definition to Planned/ Pre-Determined Curriculum is found very difficult by most tertiary academics •The best Teaching / Leaning style and Pedagogic design for different subject areas and student types are not well understood	
EQUIPMENT DEVELOPMENT	Employment of High Technology Equipment brings major additional costs and skills relating to: specification, acquisition, installation, acceptance test, operation, maintenance, housing, environmental control and de-commissioning •Failure to recognise problems in any one of these can be detrimental •Successfully Managing issues of equipment availability, performance, realistic levels of utilisation, restart & recovery, disaster recovery and the like, are ESSENTIAL to trouble-free application of the technology	
COURSEWARE DEVELOPMENT AND DELIVERY	Requires significant additional skills and capital (human and financial) to develop and deliver knowledgware

BUILDING A COMMUNITY OF LEARNERS: NEW TOOLS FOR COLLABORATIVE LEARNING

Paul Resta

PROFESSOR OF INSTRUCTIONAL TECHNOLOGY
COLLEGE OF EDUCATION
THE UNIVERSITY OF TEXAS AT AUSTIN (USA)

INTRODUCTION

This presentation describes the results of a long term study on the experiences of teachers using a prototype network-based computer-supported collaborative learning (CSCL) environment as a tool to help create collaborative knowledge-building communities. The research, beginning in the Spring of 1993, focused on the exploration of the use of this new tool for collaborative learning in both middle school and higher education settings. The Knowledge-Building Communities project was a semester-long project, funded by the Texas Center for Educational Technology (TCET) and supported by Apple Computer, the project combined the exploratory use of classroom-based networked computers and telecommunications and a beta-test version of an educational groupware program called MacCSILE.

Intensive professional development and support was provided to both the participating teachers and college faculty during the Spring 1993 project utilizing a social constructivist approach to learning, teacher-to-teacher mentorship, technology support, and collegial collaboration on-line and in monthly meetings. Computer support was provided by Apple Computer for the development of the Collaborative Learning Laboratory in the College of Education and computer placements in some of the participating middle schools. The project team, directed by Dr. Paul Resta, included Mark Christal, Adrienne Kennedy Puthoff and Karen Ferneding Lenert.

The middle school component of the Spring 1993 field-based project brought five teachers with prior experience in CSCL — specifically the classroom use of MacCSILE (a beta-test version of an open-ended networked software package for collaborative work) — into a mentorship/peer-support relationship with four teachers from another district. The project goal was to explore the nature and impact of this collaborative collegial relationship, in the presence of new technology and the challenge of designing new opportunities for their students (both in curriculum design and instructional strategies) which incorporated the new technology and the social-constructivist view of the learning process which the software specifically engenders.

The results of this initial research and development effort were promising but the question of the longer term effects of the application of this new toot on teacher practice remained unanswered. A follow up study was designed to better understand the long term impact of the Knowledge-Building Communities project and the technology itself, on the participating teachers, their thinking about curriculum and instruction, and their report and reflections about their emerging classroom practices a full year after their participation in the pilot project. The study was specifically designed to capture the teachers' voices, to hear their stories, to identify the main themes among their reflections and understandings, and to surface the implications of this pilot model for the advancement of teacher change and technology-supported innovations into today's classroom practices.

One year after completion of the initial project, a follow-up study was conducted using in-depth interviews of the original nine teacher participants. Each teacher was interviewed by two members of the research team and a third member assisted in the coding and analysis of the interview data, and in cross-

checking their codes discussing the implications and emerging themes, developing the research findings.
The analysis of the interview transcripts revealed five major themes that emerged from the teacher experiences in the use of technology-based environment to support collaborative learning and also the social cultural contexts of schools, and school change. The following sections describe the CSCL tool used in the study, the results of the study and their implications and recommendations for policy and practice.

DESCRIPTION OF COLLABORATIVE LEARNING SOFTWARE

MacCSILE, a beta version of the CSILE software program was used as the primary collaborative learning tool in the study. Conceived in the mid-1980's, the original CSILE software was the work of cognitive scientists Scardamalia and Bereiter (1992,1993, 1994) at the Centre for Applied Cognitive Science, Ontario Institute for Studies in Education (OISE), Toronto. Canada. The heart of the system is a student-generated database that begins empty, but grows as students enter their text or graphical notes Students are encouraged to address all aspects of their learning process in these notes-their wonderments their questions, their theories, their knowledge goals, the knowledge gaps, their plans for pursuing their knowledge goals, their new learning-by having the choice of stamping each entry with a "thinking type" that describes the nature of a given entry. The MacCSILE 1.0 implementation employs the thinking types "Problem," "My Theory," "I Need to Know," "Plan," and "New Learning." Theoretically the use of the thinking types helps students make their covert knowledge construction activities more overt, as well as encouraging specific cognitive learning strategies such as questioning, identifying knowledge lacks and making plans for pursuing specific knowledge goals.

In the expanding CSILE/student-constructed database, students share with others both process (reporting questions, plans, and progress) and content of their work. (Scardamalia, 1992).

The version of CSILE software used in the TCET project:

1. Provides for the presentation of topics, questions, or themes by the teacher.
2. Opens the database to any participant logged into lhe system.
3. Safeguards each entry by author-password, to insure editing of any note, comment, or link solely by author.
4. Configures the database around "thinking types" (entry indexing, generated by the author, tags each entry as problem, i.e. the focus of the student's inquiry, theory or tentative hypothesis, information needs research plan, or acquired information/insight); and
5. Promotes collaboration among learners through access to the database for:

a. reading notes retrievable by author, topic or "thinking type", and

b. interaction using "between-entnes" features of commenting on an existing note or linking between any two existing notes.

By default, all notes in the MacCSILE knowledge base are public. Each note is stamped with the authors name and the class topic it addresses, Students "own" their notes and have the choice of editing them but they may not change others' notes. The system specifically provides for student collaboration by allowing students to compose notes that are comments to other notes or link two existing notes MacCSILE facilitates collaborative communication by notifyinq a student of all of the comments made to her notes when she logs onto the system or requests the "Comments to My Notes" list.

MacCSILE also provides search functions that help make the growing knowledge base a useful resource for learning. Students may search by author, topic, or thinking type. Some versions of the software permit keyword searches as well. Since, ideally, a single CSILE knowledge base will serve multiple grades and multiple subjects in a given school, using the search functions for topic or keyword has the potential of facilitating the transfer of knowledge across subject domains, another important cognitive learning skill.

Finally, MacCSILE employs hypermedia functions for two different knowledge building purposes. As notes become linked or commented upon, the system automatically attaches navigation buttons to the notes so that students may move between comments and the target notes of comments by clicking on the buttons. making it easy to follow sequences of collaborative communications. Students may also attach text labels to text or graphics notes which are hypermedia buttons that pop up other notes, permitting students to create elaborate hierarchical representations of their learning For example, clicking a "leaf label on the drawing of a tree may allow a user to "zoom" in to a detailed drawing of a leaf in another note that may have active labels of its own.

The recommended configuration for a CSILE classroom includes 8 computers networkecd to a file server that may support several classrooms with a communal database. In the schools involved in the TCET 1993 pilot study, the recommended ideal was only approximated, with 4 to 6 computers per classroom.

In addition to the classroom sets of networked computers and the CSILE software, the TCET project technology also included use of a university-based bulletin board using SoftArc FirstClass software This College of Education/Learning Technology Center technology contribution to project activities allowed participants to be electronically linked between campuses, to engage in spirited conversations on-line to swap stories, questions, concerns and schedules through e-mail and chat functions, and to develop an electronic arena of e-mail conferences designed specifically for the project. All participants were given both the client software and cursory training in the BBS uses.

In practice, however, for nearly half the teacher participants, teacher use of She BBS was frustrated by having no computers with phone lines readily available Nonetheless, once the technology became available. the bulletin board service to teachers and to then classes became a highly active arena for teacher-to-teacher as well as student-to student exchange

TEACHER INTERVIEWS

One full school year after the completion of the Spring 1993 TCET project, researchers returned to the participating teachers to interview them regarding ther experiences, perceptions and reflections on the project and the impact which their project involvement had on them as teachers, their conceptualization of their teaching role and their on-going teaching practices. After hundreds of hours of interviews, data analysis deliberations, literature searches and interpretations, a wealth of story and teacher voice has emerged from this project.

RESEARCH FINDINGS

This research yielded a core of five themes which emerged from the teachers reflections and responses. The themes included:

Theme 1.

The knowledge-building community changes teacher practice;

Theme 2.

Support acts as the framework of a diffusion process;

Theme 3.

Adoption of CSCL transforms social interaction;

Theme 4.

Understanding "resistance" and structural factors as barriers;

Theme 5.

Teachers' visions and the new professionalism.

The themes provide the touchstones by which we can unpack and deliberate the many complex and confounding aspects of technology and the human story of teachers, students and schools in the context of a collaborative knowledge-building learning community. What has evolved are understandings and recommendations regarding technology and schools, teacher development, curriculum and instruction, administration and policy issues.

THEME 1: THE KNOWLEDGE-BUILDING COMMUNITY CHANGES TEACHER PRACTICE

The teachers in the study articulated the ways that the provision of the new collaborative learning tools and support significantly changed their practices. The study indicated that in the presence of permission, encouragement and support, technology implementation can offer a novel arena for experimentation and learning exploration opportunities for teachers. In the otherwise highly conservative, low-risk mentality of most school settings, the unknowns and the pioneering spirit of such novel work as open-ended technology applications in classrooms, afford teachers a rare and invigorating risk-taking forum. This risk-taking forum, coupled with the current cultural status of technology, further legitimates the explorations and experimentations.

Specifically, in the CSCL project and its particularly open design for high teacher involvement, the mood of teachers' openness, inquiry and self-reflection embraced many levels of questioning and reflective practice — from the perfunctory placement, management, and other basic questions (schedules, topics, specific uses, and the like) to the deep structure questions at the very heart of education and schooling (individual and community values, utility, equity, learning goals, productivity, performance, mastery, student engagement, accountability, and the like).

Both in the general and in the specific case of the CSCL project, these aspects of exploration, risk-taking and reflection undergird the development of a true knowledge-building community in which the stultified or rigid, defensive or authoritarian posture of the institution of schooling gives way to honest inquiry, purposeful exploration, introspection, formative evaluation and on-going adjustments. Grappling with substantive questions and deliberating purposively within the frame of knowledge-building learning community, teachers themselves become candid, reflective teacher-researchers.

In contemporary discourse on public education and schools, such shifts are often central themes in the literature of school restructuring or professional development. Yet these are recognized as being changes which are hard-wrought within a typical top-down institutional model. Embedded in the reflections of the teachers in this technology project is the phenomenon that these markers of restructuring or professional development actually arose — "bottom up" in an institutional sense — from the teachers themselves in the course of their project involvement.

Emerging from the teachers articulated experience is a congruent and compelling picture that technology linked to pedagogy, broad-base support, open-ended explorations, and teacher reflection represents a powerful means of facilitating changes in instructional practice.

Table 1 provides a summary of the changes related to curricular and instructional practices cited by the teachers.

Table 1

The Knowledge-Building Community and Changes in Instruction, Curriculum, and the Role of the Teacher

Changes in Instruction	
Change From	**Change Toward**
Teacher-directed practices	Student-directed learning
Independent student work	Collaborative learning
One learning activity at a time	Many learning activities simultaneously
Changes in Curriculum	
Change From	**Change Toward**
Curriculum as plan for achieving predetermined learning outcomes	Curriculum as an environment designed to enable knowledge creation in a specified arena of discourse
Curriculum is subject or content based	Curriculum environment designed around themes, projects, or problem-solving
Curriculum designed by outside specialists	Curriculum designed through collaborative brainstorming between members of learning community (teachers and students)
Tendency for curriculum to remain fixed	Curriculum under constant revision, based on past experience
Changes in Teachers' Roles	
Change From	**Change Toward**
Teacher as subject-matter expert	Teacher as learning guide or coach
Teacher as curriculum consumer	Teacher as curriculum designer
Teacher as follower of curriculum	Teacher as director of curriculum

Although each informant expressed specific-experiences unique to the alteration of their individual instructional practices as they worked to transform their classrooms into knowledge-building communities, there were some common threads woven through each of the individual teacher's stories. In fact, the majority of the project teachers shared the following changes in their instructional practices: (1) student-directed learning, (2) collaborative learning, and (3) multiple, simultaneous learning activities. Each of these elements are examined in more detail in the following sections.

Student Directed Learning

Perhaps the most obvious change noted by our informants is the change from teacher-directed classroom practices to student-directed learning. The change has been expressed as one of degree rather than an absolute change. In fact, several teachers noted that there will always be a place for direct-teach methods such as lecture, recitation, and independent seatwork, because these are such efficient methods of exposing students to basic information. Some of the teachers reported having made dramatic changes in their teacher-directed/student-directed ratio. While other teachers did not speak of perceived changes in their instructional practice specifically in terms of the degree to which it was or was not "student-directed," they were clearly making some kind of a transition towards adopting increasingly student-centered approaches based on their statements about class organization, curriculum development and instructional procedures.

A Shift in Curriculum: From a Plan to a Learning Environment

A traditional view of curriculum depicts it as a plan for achieving predetermined learning outcomes. In a given course, students participate in learning activities which are guided by learning goals mandated for that course, usually in a specific sequence. By accomplishing the learning tasks for a few learning objectives every day, they build up sufficient knowledge and skills to satisfy the learning goals set by the curriculum. In contrast, within a knowledge-building community, the notion of curriculum shifts from a *plan* for achieving predetermined learning outcomes to that of a learning *environment* designed to enable knowledge-creation in a general area of interest.

Curriculum Designed Through Collaboration Between Members of the Learning Community

Traditionally, the source of curriculum is from outside specialists who attempt to design a curriculum that will fit educational requirements enunciated by authorities at state and federal levels. Such efforts are quite capable of addressing the top-level concerns for education, but are not likely to address the local conditions of a given knowledge-building community. The approach to curriculum we witnessed and teachers reported in the Knowledge-Building Communities project is one which embraces the notion of collaboration between all members of the community in the creation of curriculum. Not only are teachers interacting closely with colleagues in brainstorming effective curriculum ideas that will work well for their local community, but students are given as much responsibility as possible in designing and elaborating significant aspects their own curriculum. "Student choice" is a phrase that several teachers use to describe the curriculum they aspire towards.

Curriculum Under Constant Revision

Once developed, curriculum which derives from such traditional sources as textbooks and state curriculum guidelines tends to stay fixed. In stark contrast, we have seen how the curriculum of knowledge-building communities remains under constant revision, based on the ongoing experience unfolding in the classroom. The ongoing goals, of course, are constant improvement and relevance to students. Several of the teachers indicated how they felt it was necessary to constantly revise the curriculum as they saw the needs of students become more apparent. Teachers indicated that, typically, the curriculum needed to be altered in order to: (1) encourage more student collaboration and reflection, and (2) have it be more appropriate to *all* levels of student ability.

Fundamental Changes in Teachers' Roles

When teachers change their instructional practice and their relationship to the curriculum, they tend to also change their role in the classroom. The traditional role of the teacher may be characterized as that of a subject-matter expert whose responsibility it is to transfer a specific body of knowledge (the curriculum, usually defined as the material in a textbook) to the minds of students primarily through the method of lecture, demonstration, and drill; evaluate the success of the transfer of knowledge through questioning and tests; and provide remediation as needed. We have seen teachers in the Knowledge-Building Communities project depart from the traditional role in three ways. First, we have seen teachers depart from a direct teach approach, so that they use less lecture and demonstration and act more as a learning guide or coach for students who pursue their own knowledge goals. Second, we have seen teachers become less consumers of curriculum and become more involved designing curriculum that is more sensitive to student interest. Third, we have seen teachers becoming less followers of curriculum as they take on the role of directors of curriculum.

The Teacher as a Learning Guide or Coach

Given that becoming a self-directed learner is something that must be learned as well, being less "teacher-directed" generally means that the teacher changes to a facilitating role for the student, leading the student toward more competency in self-directed learning. Many students will initially lack the skill and motivation to pursue their own learning goals. For these students the teacher provides a scaffolding of support that is gradually withdrawn as students become more capable of pursuing their own learning goals. Students with better learning skills will require less teacher direction, but will still need guidance and coaching as the teacher attempts to guide them toward appropriate learning goals.

Several teachers noted that the CSILE networking software helped create a classroom environment that permitted both more student-directed learning and an opportunity for teachers to take facilitating roles. For example, one teacher explains, "We saw that if we had the curriculum designed properly and the kids had multiple jobs to do that would free us up to facilitate."

The Teacher as Curriculum Designer

The conception of the teacher which emerged out of the history of education in 20th century America diminished the role of designing curriculum. Teachers are generally expected to deliver the curriculum to the best of their abilities through instruction, and typically 75 % to 90 % of instructional time is structured around the textbook (Woodward, Elliott, & Nagel, 1988). To take creative liberty with the curriculum usually entails special dispensation from the school administration. Substantial revamping or creation of curricula often requires special permission from higher administrative authorities at the district or state level. For most of the teachers in the Knowledge-Building Communities project, explicit permission for creative curriculum control came from the district or school administrative level, or both. Given that the CSILE program comes without any content and no explicif curriculum design, teachers would need to grapple with important curriculum decisions in any case. To their credit, the teachers in the project responded to this new duty in a positive way as a new professional challenge.

For the teachers in the project, curriculum design, as it is particularly required by CSILE, was a new experience, but one they undertook with interest and enthusiasm. Two curriculum elements emerged as important challenges for several of the project teachers. First of all, despite the fact that the teachers were given permission to depart from the official curriculum, many of them felt if important to include as much of it as possible in their CSILE curriculum designs. Secondly, the teachers realized the importance of making their curriculum as engaging for their students as possible.

Teachers noted the changes in their roles and views of the curriculum as a result of the project experience. For example, one teacher characterized his curriculum concerns prior to CSILE as one of "just trying to follow the district and the state essential elements." Another teacher indicated that prior to the project she "followed the State of Texas TEA Essential Elements*, the guidelines that were printed by the state...". She related that without the CSILE experience, she would not have spent very much time rewriting the curriculum. However, both of these teachers talk at length about how they spent a great deal of time designing curriculum for CSILE that would be true to the student-directed, collaborative pedagogy of the software, yet also would satisfy most of the same curriculum as outlined by the state and district mandates.

The Teacher as Curriculum Director

Traditionally, the curriculum has functioned much like a script to be followed by the teacher. State adopted textbooks supplement their content with teacher guidelines that give detailed recommendations on precisely how to teach the course content. If the traditional teacher role is one of a "sage on the stage," then the curriculum is the "behind-the-scenes" director. This arrangement tends to relegate students to the all-too-passive role of audience.

In a knowledge-building community, the roles of curriculum, teacher, and student all shift. As we have seen, teachers become the designers of the curriculum. In the implementation of that curriculum, they perform more the role of a director than simply a follower of the curriculum. They set the stage for learning, assure that the appropriate elements and materials are present, and direct their students in their active role as learners.

The teacher's position as director of the curriculum is also true in the sense expressed by one teacher's remark about being like a "traffic cop at Picadilly Circus." The knowledge-building community curriculum is much less like a script to be followed and more like an environment to be navigated. This is highly related to the change in instructional practice that the teachers described as they began taking on more the role of a learning guide or coach.

Implications of Theme 1

The teacher experiences related to Theme 1 indicate the ways the knowledge-building community requires changes in teachers instructional practice, their relationship to the curriculum, and the roles teachers play in the classroom. In order to support intentional learning, departure from what is commonly understood to be classroom practice is substantial. No longer are students strictly focused on the teacher who has the responsibility of delivering a curriculum handed down from above. The whole learning community has considerable latitude in defining the curriculum and appropriate instructional activities which further the community's pursuit of knowledge. The profound changes in instruction and curriculum also transform the social interactions among the members of the learning community. In particular, teachers, who, in the past, had isolated themselves within their classrooms and explored only their assigned subject areas, learned to interact more with their colleagues in the knowledge-building communities and expand their curriculum content. Students also experienced their relationships with learning and fellow students as being transformed in substantial ways. For instance, students gain much more of their learning through peer interactions, while they become more aware of their own processes in the construction of knowledge.

THEME 2: SUPPORT ACTS AS THE FRAMEWORK OF A DIFFUSION PROCESS

The teachers interview data provide insights into their perceptions of how introducing technology alters social interactions among colleagues involved in a specific project; how such an innovation effects the overall school culture; and how the use of CSILE (and social-constructivist instructional practices) alters the social interaction among students within the classroom. The alteration of social interaction among the teachers generally illustrated what may be called "power shifts," resulting in interactions reported to be characterized by a "why them and not me" attitude. Yet, the reported changes in social interaction were complex. For example, in one school the introduction of technology fostered a "why them not me" perspective among certain teachers as well as providing a forum through which teachers could share technical expertise and instructional uses of technology. Changes within the classroom reported by informants indicated a broad range of positive and negative social interactions. Some children who were not active participants in traditional classroom settings became enlivened with the introduction of CSILE. Others seemed to exhibit some form of "resistance" or rejection of the technology and/or a collaborative approach to learning.

According to informants, CSILE acted as a motivating force, and in combination with self-directed learning, seemed to engage students to the extent that discipline problems were greatly reduced. Yet it is interesting how some informants perceived technology, including CSILE, simply as "bells and whistles," while others focused on CSILE's power to facilitate student collaboration and social interaction as the cause of increased motivation. This mix of specific perceptions about CSILE illustrates how teachers hold various perceptions and assumptions about the importance of instructional technology in general. The mixed attitudes of how technology (and CSILE) acts as a motivating factor, and the particular changes CSILE engendered in social interaction among colleagues, indicate that teachers construct particular attitudes and social discourses about technology and education. As expressed by some of the informants, these attitudes and discourses often feature specific allusions to descriptors such as "fear" or "resistance."

THEME 3: ADOPTION OF CSCD TRANSFORMS SOCIAL INTERACTION

The interview protocols provide useful insights into the informants' perceptions about certain barriers to the realization of a knowledge-building learning community. Analysis of these perceptions revealed how the notion of support covered a broad area of needs arising from the process of change. The special nature and circumstances of the diffusion of CSILE into these schools circumstances - specifically as a collaborative research project with many levels of support – offered teachers the unusual

* *Texas has a set of learning outcomes required for the core curriculum in all public schools, called the Essential Elements. Many school districts require that teachers document their coverage of those state requirements. Mastery of the Essential Elements is assessed with a statewide achievement test, TAAS or the Texas Assessment of Academic Skills, which students must pass in order to receive their high school diploma. The Essential Elements is currently being rewritten for all subjects, and will be called TEKS, Texas Essential Knowledge and Skills.*

experience to reflect upon actual and potential barriers arising from political, economic and social spheres. Their responses indicated the complexity of the diffusion and adoption processes, and that the diffusion process is largely framed by policy. For example, a thread that weaves throughout the interview data pertains to the differences in needs and perceptions between the two districts in the study, indicating that social-economic and cultural factors permeate and strongly influence the diffusion process.

The informants' responses clearly indicate that diffusion of innovation in an educational setting must address the context, the social/cultural environment in which a knowledge-building learning community evolves. In terms of the ecology framework of diffusion, the social aspects of change (diffusion) on a macro level is engendered through policy. Whereas the social aspect of change on a micro level is realized though collegiality (adoption). Yet the adoption process itself is made even more complex by another variable related to the social context — "resistance."

To contemplate the notion of adoption is to conjure the opposite process — "resistance." The three interrelated elements — adoption, "resistance" and collegiality —function under the umbrella of the diffusion framework and together create the contextual and social dynamic of change. Given this, a bottom-up model of diffusion, as featured in this project, requires us to revisit typical assumptions about "resistance" and how it configures the adoption process.

THEME 4: UNDERSTANDING "RESISTANCE" AND STRUCTURAL FACTORS AS BARRIERS

The data analysis indicated that the adoption of CSILE is both enriched and made complicated by the purposeful design of the technology itself. Because CSILE acts to shape or scaffold changes in teachers' attitudes and behaviors, it was evident that CSILE exits not only as a tool, but as a social process, since both pedagogically and procedurally CSILE engenders changes in social interaction. This is evidenced by changes cited by the informants in several realms such as their teaching practices, beliefs in learning theory, and alteration of social interaction amongst colleagues as well as within their classroom settings.

Analysis of the informants' experiences also showed how perceptions about the construct of "resistance" can affect teachers' adoption behaviors, as can their perceptions about the traditional uses of technology in education. The typical understanding of "resistance" as a private, individual experience characterized as fear or phobia of technology may add to or in fact act to rationalize the divisiveness between those teachers who are "pro-technology" and those who seem to be "resisters." Some teachers are in fact "resisting" the use of computers in education because they fear or feel mistrust towards computer technology in general. The issue we must consider is that their concerns may be justified on some level given the problematic history of technology diffusion in education. In addition, when an innovation is introduced, due to existing structural forces, teachers are positioned to make "situationally constrained choices" (Cuban, 1993) — a factor which directly affects the adoption process. Other important issues raised by informants were related to the possible danger of using technology as an end in itself and the influence of equitable distribution of hardware within a school, in terms of how this affects collegiality.

Despite the fact that most informants experienced some "resistance" from their colleagues to the diffusion of CSILE and other computer-based technologies, the informants' collective vision clearly indicates the perception that the diffusion of electronic technology into education is "inevitable." This perspective was strongly expressed by informants from one of the two participating districts which, at the time of this study, was formulating plans to install a district-wide telecommunications infrastructure.

THEME 5: TEACHERS' VISION AND THE NEW PROFESSIONALISM

The Knowledge-Building Community model of instruction is so well supported by technologies such as CSILE that some of the informants could not envision such a learning environment without the use of CSILE. In addition, many of the teachers expressed how CSILE, because it embodies a social-constructivist theory of learning, also has the capacity to change the teaching practices and learning experiences of those who are exposed to it.

In fact, for many of the informants CSILE offered support whereby their teaching practices moved towards the direction of collaborative, intentional learning.

At the school level, learning technologies such as CSILE can make social-constructivist based instructional practices more feasible to implement into practice by the nature of their design. For example, by using learning technologies that support intentional learning, teachers find that their teaching practice changes to accommodate such learning. In effect, a technology such as CSILE is purposefully designed to embody social-constructivist learning theory. When used in a classroom setting it can act as the scaffolding whereby teachers move from a traditional teacher-directed instructional style to one which embraces collaboration, generative, intentional learning and an interdisciplinary curriculum.

Even if teachers do not use CSILE, as the informants suggest, exposure to it can invite reflective thinking on common sense assumptions about teaching and learning. However, we are not advocating that the mere presence of technology in the schools, guarantees adoption of social constructivist-based instructional practices. If schools adopt learning technologies whose design is based on the instructional theories which emerged out of the industrial age (i.e. behaviorist inspired), then information age instructional practices based on collaboration and communication are not likely to come about. In effect, schools need to consider the relationship between the qualifies of a technological innovation and the desired changes in instructional practice.

Many of the teachers' understandings about what type of learning technology was suitable for supporting their CSILE-inspired vision of instruction not only included CSILE. In fact CSILE was but one component of a mix of technologies that expressed their emergingvisions and concepts about instruction. Three specific technological components in particular were offered by some of the teachers, in terms of the requirements for technology-supported classrooms: a networked configuration of computers, telecommunications, and expanded access to various sources of information. These three components are so highly interconnected, that it is often difficult to speak of them separately, so we have grouped them all under the general term, "connectivity."

Networked classroom computers running CSILE provide a public space for knowledge-building within and between classes at a given school. The knowledge-building community, however, becomes widened when other schools and outside experts interact via telecommunications. Telecommunications, especially Internet resources, also bring into the classroom a vast repository of information that students may use in their knowledge-building research along with non-networked information resources such as CD-ROMs and traditional information resources. The connectivity with teachers both within and between schools enhanced their own sense of professionalism and greatly reduced the sense of professional isolation typically encountered by teachers who spend the greatest portion of the day in their classrooms isolated from their professional colleagues.

Connectivity is a powerful means through which the barriers of space and time collapse. It enables students to engage in knowledge-building activities, and allows teachers to enhance collegial interaction through collaboration with each other, outside experts, school administrators, parents, and support personnel in their role as professional educators. Connectivity offers not only the possibility for new methods of instruction, but it offers a new level of professionalism for educators as well. Previous learning technologies, such as Computer Aided Instruction and Integrated Learning Systems, are based on older models of instruction, and, according to some researchers (Apple, 1993), had the effect of deskilling the teacher. These technologies, some of which were described as "teacher proof," acted to undermine the need for teachers to make essential curriculum decisions. Learning technologies based on information age connectivity, when associated with social constructivist theory of instruction, however, place the teacher at the center of educational decision making, requiring her to work closely with colleagues in the design and implementation of curriculum and assessment.

Connectivity also has the potential to facilitate collegial interaction by providing forums for the collaboration process. Teachers between schools can augment their face-to-face planning with telecommunications, as well as utilize educational resources available on the Internet. However, connectivity also brings with it a new set of teacher and administrative concerns, as it demands changes in more than just classroom instructional practice — it most likely will require changes in the very structure and culture of education itself.

Making the kinds of changes in the structure and culture of education that will allow knowledge-building communities to become commonplace is an immense challenge which we have only begun to address in our study. If we decouple the notion of connectivity from the technological hardware, then what is left are social technologies (conventions and practices) that bring people together in effective ways to address educational aims. At the classroom level, collaborative learning, with or without computer support, brings students together with other students, guest experts, teachers, and information in the service of knowledge building. In the sphere of collegiality, collaborative curriculum development brings teachers together with teachers and educational consultants to devise a curriculum suitable for a knowledge-building community. At the level of policy, there are approaches to institutional decision making that embrace the input from all the members of the school community in collaborative deliberation.

OVERVIEW OF CONCERNS AND ISSUES EMERGING FROM THE RESEARCH

In a computer-supported knowledge building community framework, new "collaboration-friendly" technologies (groupware, networked databases with collaborative writing and commenting functions, e-mail, etc.) provide a robust social-cultural forum for teachers, students, and other partners in a learning community. Based on what the teachers shared in their interviews, technology diffusion activities work synergistically and effectively in two important dimensions: 1) in introducing teachers to technology and 2) in engaging their interest and commitment to change.

To be successful in fostering a sustainable technology-rich school culture and learning environment, technology diffusion must include the following key components:

- networked (preferably classroom-based) computers, telecommunications, and configurable open-ended software including such features as an empty database with structural or organizing options, procedural prompts, and multiple search options;
- a generative pedagogy based on sound learning theory and the cognitive sciences, which is open to individual teacher interpretation and experience levels;
- open-ended exploratory curriculum applications designed by the classroom teachers themselves;
- active teacher development, including reflective teacher practice, collegial exchange and interaction;
- administrative support and policy which allows inquiry, risk-taking, collaboration and shared decision-making;
- project design and seamless research activities based on advocacy and action research which likewise promote authentic engagement and ownership of teachers and students.

The Human Dimension

Teachers in supportive settings explore and appropriate open-ended technologies as an extension of their understanding of themselves as educators; their understanding of curriculum design and their sense of personal, direct design involvement; and their understanding of instructional practices, both traditional and familiar, as well as those new to them.

In supportive settings, experienced teachers come to open-ended technology opportunities in much the same manner that they might examine a new textbook series, compile ideas from an instructional workshop, or conceive of designing modifications to existing assessment practices. One teacher may work initially out of his/her sense of teacher as an content guru or as a process innovator. Another may work from the posture of an adventurer or risk-taker. Still another may come to the experience as a meticulous planner monitoring or imposing high structure on each fragile detail of a careful beginning.

From an overarching bird's eye view of a teacher's initial or primary relationship with technology, we have observed that, while some teachers aggressively embrace technology from an innovative sense of design and implementation and as a direct part of a larger teaching mandate, others approach technology with a staid or minimalist sense of using technology as a subtle substitution of some learning activity already" existing in his/her traditional teaching practice.

Indeed what we witnessed repeatedly — with the open-ended and supportive/exploratory nature of this project — was a remarkable continuity between the technology approach of each teacher in the study and who they were and/or how they understood and conducted their teaching roles prior to the technology. In each case, the initial uses as well as the subsequent assessment issues which emerged over time had the unmistakable fingerprints of the individual participating teacher. Each appropriation of the computers by either the more technology-experienced or the more technology-novice teachers was clearly reflective of the particular teaching style; each application was stylistically each teacher's own.

The important distinction here is that the applications which teachers made of the technology were related more strongly to who they were, how they saw themselves as teachers, how they understood their teaching roles, and how their existing practices could be incrementally stretched, guided or expanded by the technology than to their technological sophistication, practice or familiarity or their technology interest or advocacy. The significance of this finding to the design and implementation of the collaborative learning tools is evident in the teachers' own stories.

As was documented in the original TCET project and confirmed in the follow-up interview study, project openness and the openness or malleability of the technologies can provide participants a window to view the nature of adoption from a wide range of teacher backgrounds and teaching styles. In studying these phenomena, the authenticity of the teacher responses — both to the appropriation of the technology itself and to the interview questions — confirmed the openness of the project, as well as the openness and malleability of the technology.

In the study we additionally confirmed that teachers develop new practices, usually linked to successful past practices, as they incrementally come to understand and integrate a new pedagogy and the innovative aspects of technology. While this may seem obvious and commonsense, the nuances of this position have significant implications for the technologies we choose in technology diffusion plans or the manner in which pedagogical shifts, or changes in curriculum and instruction, are brought to teachers. This too will be further discussed below.

In meeting the technology challenges and in implementing their own classroom explorations, teachers are validated and strengthened in two important, mutually supportive dynamics:

1) their sense of ownership of the technology and

2) their direct action in shaping their curriculum and instruction to optimize the available technology.

This validation of the person of the teacher is the pivotal point in developing and supporting teachers in an arena of professionalism and personal efficacy. When each teacher personally works to interpret and filter a technology for his/her own classroom practices, the technology itself becomes *not* an externally-grafted requirement or expectation, but an individual professional decision and a design question integral to curriculum and instruction issues. In our study we repeatedly found teachers who — with the added challenge of technology integration — were actively asserting themselves and engaged in curriculum and instruction in wholly new or rekindled ways that they had rarely experienced or that earlier might have been unimaginable.

Notwithstanding the added job complexities and time-consuming adjustments to technology implementations, many teachers in the project displayed high involvement, enthusiasm and increased interaction with colleagues and other project participants as a direct result of needing to work through the unknowns and the challenges. Under an open-ended exploratory model of technology diffusion and the built-in interest and capabilities for collaboration, the technology itself becomes a powerful social, intellectual and pedagogical artifact in scaffolding teachers' own learning and in sparking necessary changes for teachers, as well as students. When the threat is low (an encouraging learning-community environment) and the potential reward high (seeking to fulfill a professional goal or create an innovative curriculum milestone), teachers engage in reflective practice and seek out collegial connections and collaboration as part of pursuing and incrementally working out their own on-going professional development in technology applications to their classroom practices.

SUMMARY

This study has shown that the introduction of CSCL environments like CSILE has the potential to alter both the structure of classroom discourse and the school community. Yet the opportunity to capitalize on the benefits of connectivity may not be fully realized if their adoption only serves to support elements of the existing system and the traditional organization of schools. Therefore, the process of adoption itself needs to be seriously addressed, especially in terms of the role of teachers and the underlying pedagogical assumptions of the technology.

We have discovered that teachers' resistance to technological innovations may be discounted and/or misunderstood. Historically, teachers have been excluded from the decision-making processes within schools, especially in the case of top-down reform campaigns based on technology infusion. Also, the current structure of schools creates for teachers a "culture of individualism." However a formal approach to school decision-making based on teacher collaboration would challenge and potentially reverse the tradition of teacher isolation.

Although there are several models which guide the organizational changes of schools, many have been adopted from the field of business administration and therefore do not address the importance of building community specifically within school settings. However, the approach to curriculum adoption developed by Schwab (1993) is unique in that it addresses the decision-making process itself. Schwab's approach characterizes the adoption process as collaborative decision making and emphasizes the central role of the teacher. His approach is examined more closely in the following section. Schwab's deliberative approach to decision-making outlined in his four papers on "the practical," offers a community effort of deliberation shared by students, parents, the school principal, community members, social scientists and professional academics and especially teachers. In fact, the role of the teacher is central to the decision making process. Noting that "teachers practice an art," Schwab (1993), believes that the process of active involvement in deliberative decision-making "constitutes the only language in which knowledge adequate to an art can arise" (pg. 245).

Unlike typical models of diffusion and adoption created from business and industry's guiding principles and goals, Schwab's model pertains to the specific needs and goals of educators and schools. His framework encompasses all of the "commonplaces" of education: students, teachers, subject matter and social-cultural milieu. His approach would therefore address the contextuality of technology adoption, including the influence of political concerns: The framework, however, is designed so that each of these commonplaces bears equal weight. Each commonplace is examined in its full range of complexity, as the framework utilizes an "eclectic" approach to deliberation of concerns and issues, inviting a variety of contending perspectives, viewpoints and theories. Thus, the concerns of those who question or resist the infusion of electronic technologies into schools would be given a safe forum for discussion.

Schwab's framework applied to technology adoption would characterize it as an ongoing process. Technology adoption and its integration into curriculum would be seen as a trial and error process of discovery characterized by flexibility and open-endedness (versus blame and "failure"). In effect, Schwab's approach could act to "scaffold" a "convivial" (Illich, 1973) approach to the realization of CSCL environments. A "convivial" approach fully recognizes both the benefits and limitations of a technological application/innovation. This balanced (and less naive) understanding about a particular technology becomes anchored through the process of deliberation and discussion. The resultant guidelines and stated values become integrated into adopted policies which guide the instructional aims and applications for an educational technology. In effect, the outcome is a reflective model of technology adoption and diffusion. This reflective aspect is imperative as our technologies become more powerful and complex.

RECOMMENDATIONS

The five themes which emerged from the data analysis indicate how a CSILE based CSCL environment can scaffold the transformation of teachers' instructional practices and ultimately change the structure of classroom discourse. If was also discovered that the introduction of CSILE caused "power shifts" and transformed social interaction within the school community as well as in the classroom. These shifts in social interactions are dependent upon support from the realm of policy (fiscal, leadership and teacher development) as well as the school community. We also found that the technology of CSILE as a "philosophical framework" not only aided teachers in transforming their instructional practice but also influenced a re-envisioning of their professional roles; especially when they considered the general "inevitability" of the diffusion of networked telecommunications systems into education. This is very powerful.

The interaction of the three major components (school community, the technology, and the realm of policy) underscore the breadth of contextuality and complexity which characterize the conceptualization and realization of a CSCL knowledge-building community. The networked systems scenarios outlined by Morrison and Goldberg (1996) indicate that *our values and normative understandings about schools* tacitly, if not overtly, guide the application of a technology. Thus support, in its may forms, acts as a framework for adoption. *This factor becomes especially important if the technological innovation, as with networked systems technologies, possesses the power to alter our relationship to time and space and ultimately change social interactions (i.e. discourse structure and "power shifts").* It may be that the traditional models of diffusion, and the assumptions which guide them, need to be abandoned or augmented by an approach which questions a dominate cultural bias, which is to approach technology as a solution to social problems uncritically (Segal, 1996) and apolitically (Winner, 1980).

Based on the findings presented in the data analysis and the summary sections of this paper, we make the following recommendations:

- Technology "adoption aimed at creating a CSCL environment guided by social constructivist pedagogy needs a structure which *invites* the concerns of those typically excluded from participation in traditional, top-down models of infusion. We strongly recommend that educators review the work of educational researchers who have developed models of *community-based approaches to reform* which support collaborative decision making. No matter what approach to decision making a school employs, a *deliberative approach is central* to the success of collaborative efforts, as it gives equal weight to the commonplaces of schools and invites a wide range of perspectives, including those which counter the status quo. Although Schwab's approach, for example, focuses specifically on curriculum development it could also be applied as a framework to the practice of technology adoption on the level of school communities, as well as diffusion, which includes the realm of policy (building level and state administration, and to some extent, federal influences).
- Commitments from the micro (School Community) and macro (Policy) levels are required to support the necessary changes to make CSCL knowledge-building communities a sustainable reality. Such changes may include alterations in school culture by means of shifts in power structures including the discourse structure of the classroom, the professional responsibilities of teachers, and the general hierarchical power structure of schools.
- Changes in the discourse structure of the classroom requires teachers to become actively engaged in students' lives. In order to support teachers' efforts to become effective and compassionate advocates of students from diverse populations, the training of teachers in methods germane to CSCL knowledge-building communities also needs to address multiculturalism.
- Teachers must have time for reflective practices, especially as they adopt roles as curriculum developers and engage in an iterative process of curriculum and instructional development. Teacher collegiality and collaboration amongst teachers must be encouraged and supported in a climate of professional status and respect.
- Educators involved in the adoption of educational computing technologies need to be more mindful of the underlying assumptions which relegate certain student populations to only a few specific instructional technologies (i.e., low SES or "at risk" students' needs best served by drill and practice instructional software). These underlying assumptions may in effect serve to create inequities regarding student access to more empowering tools of educational computing (i.e. CSCL, telecommunications, multimedia).
- CSCL approaches to education implies new skills for practicing teachers and administrators that in the past have not been a part of the typical training programs. Colleges of education and teacher education programs should reexamine their programs in light of these new skills. For example, experience in team building and negotiation become necessary and fundamental skills to engage successfully in CSCL knowledge-building communities.
- Given that innovations such as CSCL face significant challenges in overcoming the common sense notions of schooling, a key element in effective support is the need to educate not just the immediate school community (administrators, teachers, parents, and students), but the community-at-large, about the pedagogy, educational philosophy, and educational research behind the knowledge-building community approach and the technology that supports it. The public already expects to see computers in the schools, but this expectation must be cultivated toward greater understanding and awareness of the collaborative and knowledge-building applications of not only computers, but network system technologies.

REPORT

Yves Brunsvick

HONORARY PRESIDENT OF INTERNATIONAL BUREAU OF EDUCATION
VICE-PRESIDENT OF FRENCH COMMISSION ON UNESCO AFFAIRS

Quick development of technologies has brought about such upheaval in conditions and practices of education, which was difficult foresee and which has brought about deep changes to the educational system.

The cybernetic space constitutes a parallel and constantly expanding world, which resembles a sensor world and will be occupied in the nearest future by millions of operators and will present to youths, students, men and women wide volumes of numerical information. What is more this infinity of virtual worlds must be accessible, unless for everyone, but, at least, for majority of people.

«Mathematization» of reality, being manifested itself with speeding up of its development, poses a lot of problems confront of our society, weather concerned about the inevitable confusion between reality and «virtuality», about manipulations and deviations, caused by it, or about probabilities of inequality of possibilities, which it will intensify.

Can this be imagined that corps of teachers would ignore a shock being triggered by promoting of digital technique and discovering of virtual spaces mastered by man?

The digital technique promotion and availability of data compression are the general phenomena at the end of century. This is the basis of «globalization» of intellectual, industrial and trade exchanges.

The consequences of this process are out of norms and measures of control, intended to TV and telecommunication; they create a whole scale of interactive programs, integrating a word, an image and a sound together, in one unit.

What influence on educational systems can be and would be from the side of the consequences of so-called cultural shock in cognitive process, in management of school programs, in estimation of their efficiency?

What would be the educational potentials of Internet type networks?

Trying to ignore the new information technologies would mean to remove a part of young people from the formalized training and to enable the degradation of secondary education.

Unless the purpose of each training stage is the effectuating of cognitive methods through better strategy of training? First of all, the case in point is assisting the teachers to absorb the new knowledge along with their professional career, to teach better and in different way. From this point of view they should, most likely, to learn, first of all, to convert the information into knowledge, making this in the world, in which people shall be separated only by cultural frontiers. To a greater extent than earlier, they should elaborate pupils' analytical properties, critical approach; they should be care of pupils' development of taste, of their due quality estimation, that means criteria, which are hard to survive in mathematized, non-sensored world.

In new pedagogy some principles of programmed training will take up their place: information is divided into elementary blocks, each person is educated in its own rate; intentions of developer must be clear and comprehensible, distinguished from the commentary and recommendations.

In appearing new process of getting the knowledges must find a place active methods, in particular, access to databases for getting the bibliographic references or necessary information; such access will soon become part of the normal mechanism of getting the knowledges in school and university training.

Teachers' corps ought to become implicated into emanating shock, to be the participants and (why not) the actors of changes, which are to be controlled.

Exactly on the share of teachers – and in the first place – will fall out responsibility for the conservation by the school of its place in the society; exactly they will come to keep a check on that information society become a society of knowledge for everyone, where teachers and instructors will find their worthy position.

It is in school the initial contacts of person with the others take place. Nobody denies that it is the best factor of social unity. Unless in school teaching time the necessary realizing of common values set, being of our cultural property, the erosion of which will promote a world without frontiers, surrounding us?

Unless a school should be remained as a place, in which all children of school age teach on equal, using educating facility, provided by new information technologies; a place, where the teachers and instructors can develop and create their own CD-ROM?

The similar pedagogic approach can ensure a motivation and prestigious value of work, show new behavior modes, which assume the new role of instructors and, undoubtedly, its willingness to work, in frequent occasions, in one team, in a framework of renewed profession.

Away from this, it is a cause for a content of users' background of multimedia products of unequal quality and, in frequent occasions, of controversial.

One can envision that the lack of interest and learning motivation, which distresses the teachers and instructors nowadays, will be lowered noticeably.

The teachers are in a center of problems which are the result of changes in our society: they can be confined by following to those changes, can slow down them, can control over them.

At the European countries meeting, organized at the end of April 1996 in Warsaw on the initiative of the International Bureau of Education for preparing the International conference on educational problems, the topic of which should be role of teachers in changing world, there were accepted the following recommendations relating to new technologies:

- it is imperative that the educational system would master these technologies for to avoid any technological, cultural and economic dependency, as well as any marginal transformation of school with respect to the external world;

- the positive influence of NTIC on organization of teachers' and pupils' work, the access to information, the satisfaction of individual demands, the development of cooperation, the opening of the world through the creation of networks;
- the condition of their successful using is not only technical approach, but increasing of pedagogical potential by cooperation between organizations for software development, granting an access to ICT over timetables, ensuring accessibility and integrating in network;
- intercomplementability with respect to other approaches, as at a rate of class and pedagogical activity, in the field of unceasing preparing the teachers (way of remote formation);
- the unique function of teacher, implying that the information is to be converted in knowledge, that the mastering of choice and critical estimation is to be brought up and, on the other hand, that the cultural traditions are to be transmitted as «a way of existence of human being», to install personal and social relations, promote a development of personal and social contacts, living in the community and realizing of common values;
- the necessity to develop researches and mutual use of information on influence, role and limits of using ICT in education;
- the necessity to stimulate the cooperation between institutions at the national and international level, to encourage the comparative studies;
- the necessity to take care of recent investigations for strategies of ICT application in education (European Union) and results of 2-nd UNESCO Congress «Education and Informatics» (Moscow, July 1996).

To master to learn, to master the new technologies of work, to master being oriented in hypertext, to reveal for oneself the unlimited possibilities of cybernetic space, to discover for oneself the resplendence of data bases, learn to apply them, and all this in order to convert school radically and provide a road - according to remark of Pierre-Jilles de Gennes - to «such education, which opens for youth not previously created world, but that, which would be created».

If a man do not want to be a toy of future, may he constitute it by himself?

TECHNOLOGIES

Plenary

WHAT TECHNOLOGIES ARE USED IN EDUCATION? NEW EDUCATIONAL TECHNOLOGIES IN THE DEVELOPMENT PERIOD

Jean P. Arnaud
NATIONAL SCHOOL OF ART CRAFTS (CNAM),
(FRANCE)

1. IRRETRIEVABLE CHANGES

Many of us can appreciate the technological progress in the field of education comparing former pedagogical methods with the methods, which are now widely used in the countries having appropriate industrial structures. The following funny stories can serve as a good illustration of the situation.

French schoolchildren of the 'baby boom' period while at school get to know much better the 'music' of the multiplication table than the music of the national hymn. Music helps to recall the words which are forgotten, but not many people could claim without any doubt, that the multiplication table by 12 may be a useful knowledge which must be stored (1 multiply by 12, 12 multiply by 12: how many adults could easily give the answer and at what age?). The use of calculators in everyday life and in examinations has freed us from mental gymnastics, doubtless partly useless, and the simple way in which we can get the answer within ten decimal points only corresponds to the difficulty with which pupils can evaluate the answer and check up its plausibility. At the first congress of UNESCO on informatics and education J. Weizembaum spoke about the following experiment. The schoolchildren were offered a simple problem: how many buses are needed to carry 256 passengers provided that each bus has 50 seats. The pupils were quick to give the 'correct' answer (5.12 buses). Needless to say that the correct answer is 6. All teachers doing research work know how helpful were the means of machine schedules when teaching mathematical functions. Many teachers are also aware of the difficulties with which more advanced students evaluate the order of the value of mathematical or physical result; the initial figures are set precisely, it is enough to make an input mistake (to leave out naught for example) to get the answer by 10 times less or greater, but the evaluation of the answer in the physical sense is not made. Can we contemplate the progress if the rules of calculation are passed to calculating devices and computers, if the progress in the exactitude of the answers is paid off by the regress in the evaluation of the calculated phenomenon?

In Jule Ferri's school it was considered good form to learn by heart the list of the prefectures and superprefectures of the ninety three French departments. Who would encourage such «mental gymnastics» these days, if it is enough to use the terminal of the Internet to get the list of these departments, the complete data about economy and geography of the departments, especially as all the information will be supplemented with photographs which could not be found in any historic data of any file of any scholar, *and not a single professor would be able to restore them from memory?*

But who can be sure nowadays, that our students know how to get access to the information they need through the Internet in a shorter period of time than the teacher who knows nothing about the methods used in XIX century to find in his personal library the book which contains the synthesis of data on the search; this is not a favorable comparison for our Internet users. Can we be sure that within the World Wide Web local geographical data may be easily found using thousands of references, which are caused by a simple demand in the process of search. These two examples, and any teacher can add his/her own examples generate a few questions which will be in the form of the theme under discussion.

The question can be set: what is the use of the in-depth knowledge of information and computers? If one takes into account that at the present moment informatics is the pivot of economic activities, then it is necessary for every student, for every pupil at secondary school should get basic knowledge on the subject. But would if not be a mistake to believe, that the knowledge «about something» (what is the computer, what is its architecture, what are its functions) can give knowledge of information and its use? The person working with gas-mines has to learn about gas-mines, the mechanic has to learn about gas-mines, the mechanic has to learn mechanisms, the physicist has to learn physical laws; but the electrician does not have to master Maxwell's equations, and gas-main worker does not have to learn hydrodynamics. At the first stages of the introduction of computers into education the computer was regarded as the object for learning. No doubt, it is important for the professional in the field of informatics, but is it necessary for the user to learn the computer's architecture to solve his problems?

The Industry of information, its transformation and transfer leads to the increase in the number of new professions. Such increase is accompanied by the change of the paradigm of informatics as a discipline: the problem is not to connect the terminal to the computer to ensure processing, the problem is set to establish connections between people and institutes to divide the information. Consequently, businesses pass from the information processing to the communication informatics: this will be the main purpose of the theme "information superchannels" for our system and our education methods.

Parallel to this technical changes the unprecedented social and economic changes are taking place The distance in space between places of work, people's homes and educational institutions results in the fact that the borders between them are not so clearly defined: people get education at their place of work or at home, the working time is increasingly devoted for the search for information, which is one of the main components of education and the means of acquiring knowledge. Do the information and communication systems which are used at educational institutions meet the demands caused by the above changes? Can education remain concern of only one country or nation when global computer networks come into being?

Doubtless, the issue is in the focus of our debates. Nowadays the acquisition of knowledge is not necessarily limited by the period beginning when people are young and finishing when they become young adults: school and the first years at university provide people with education, but this period of education does not come to a close when one begins an active life. Everyone has to renew, to enlarge and to change several times in a lifetime his/her knowledge and skills because of the developing technologies and constant changes in social and economic fields. It should be mentioned that the mastering of new information technologies would be faster if the process of education was conducted in accordance with the requirements stipulated by the sector headed by J. P. Arnaud, an economist. The application of informatics in education was realized faster in the sector of continuous education, especially in the field of informatics, than in the sector of primary and university education.

Actually, the use of new technologies in education can be described using three characteristic features of education if we understands it as we are used to understand. These characteristics are really the rules of the classic French theater:

- The unity of place: both teachers and students come to the educational center (school, university, center of continuous education, enterprise);
- The unity of time: at the appointed time (very seldom it is everybody's choice) students assemble in the classroom;
- The unity of action: they do it to listen to the teacher or to do excersises or to take part in a test.

New technologies make it unnecessary to meet this main set of requirements, comprising the three ones mentioned above. That is why this technologies make the education more open in the sense of receiving information for professional needs. But in this case the same number of problems, as compared with those already solved, arise:

- Is it possible to get such education as easily that is to obtain information for individual learning?
- What is the role of the teacher in such a situation when his presence seems to be unnecessary, even more so, because the student does not know how to get in touch with him in terms of time and space; who will define the contents of learning: the student or teacher?
- How does the student becomes part of the system, can he be sure that he will get an adequate education? Is it better to teach the student to use the technologies before he masters them? Sometimes discussions of the professionals in the field of education seem only to be part of similar discussions which have been held on these problems for some time in industry.

In both cases what is necessary is to find the way which will enable users to master engineering technologies. Thus, within the framework of the subject under discussion it would be interesting to consider the progress which has been made in the application of informatics to economics, which as it is believed, the most advanced students of our educational institutions study at present. This issue will be considered in the next paragraph.

2. FROM THE INFORMATICS OF DESIGNERS TO THE INFORMATICS OF USERS

2.1. Technological changes

Recently we have witnessed rapid technological changes; however, the fact that informatics was remarkably stable during the first 20-year period of its history, escapes one's memory. At that time the aim was to provide professionals in informatics with the means for data processing, supplying them with terminals which ensured access to processing devices (computers). Equipment was being improved in various ways (the increase of computers' efficiency), the application of equipment using monitors and keyboards instead of peripheral equipment using punched cards, the development of devices with operative memory, etc.). These changes allowed not only to make progress in technology, but to meet the most urgent demands in terms of memory and processing.

By the late 80s the tendency became obvious which was entirely different from that mentioned above: the installation and application of large networks, the development of communication architectures provide users with new models to organize information system, that is the first time when the paradigm is changed, that is not data, but the information is placed at the center of the information system. In this case the role of informatics changes: it becomes not only the means of 'information work, but means of acquiring management skills. Nevertheless, it is not the user's working tool. Taking this into account, at the first congress «Informatics and education» several speakers (see, for instance, the speech of P. Douge the clearly defined the borders between the «limited» and the «total" (sweeping) approach. To put it in a simplifying language and with reserves one can say that the main problem at the moment is the following: mus» everybody - students and teachers - learn programming and computer architecture irresponsible of the subject studied? This way of formulating the question which is well justified when it is in line with debates in industry and economics, has resulted in the increase in the number of all kinds of institutes. These institutes aimed at dissemination of information science («science informatique»), the mastering of which was regarded as a necessary condition to maintain full employment In this connection France can present a significant example: The World Informatics Center was set up; lycées and colleges were equipped with computers not taking into account the fact whether they are in keeping with the production used in industry; it was not taken into consideration because the purpose was not to teach how to use the means of information processing, which graduated students will then use in businesses and industries - their future places of work. The aim was to provide education in informatics, which itself was regarded as science and technology.

The 90s came to destroy this scheme. Two events caused an enormous impact in the world of information: the wide use of microcomputers as a means of access to information, and the mass use of networks with various architecture.

In the early 80s, when there appeared the first models of microcomputers, professionals in informatics were skeptical. From the user's point of view the computer was (now) the means of learning and the means to avoid influence of information management. Microinformatics technologies are the simplified technologies of traditional informatics; in fact, the personal computer has a limited power, a limited operative memory and peripheral memory devices. But by the late 80s this scheme undergoes changes, especially when the conception of the interface «man-machine» came into existence as well as new graphic devices as a result of research work, particularly, that carried out by the firm Xerox. Since then the trend in innovations has sharply changed in direction and microinformatics has become a separate independent area. As the new industry (the companies Apple, Intel, Microsoft) was growing more powerful, the existing poles of industrial development were shifted in the direction of the unprecedental growth, of the computer park at the users' disposal.

The computer which was first used as a personal means, was then increasingly used as the most preferable means of access to information.

This change was accompanied by profound changes in the technological area. When the personal computer was first introduced it was supposed that it would be absolutely the best as compared with other means of data processing: complexes of calculating devices, text-processors, archive devices, printing devices, which were designed as peripheral devices. The computer used as a mean of access to the information system is connected with the network and enables to gain access to any source of information and processing device irrespective to their location: with the user or at a distance. We have passed from the age of microinformatics to the age of networks.

In the time when the increase in the park of computer means actually becomes exponential, the introduction of local networks drastically changes the manner in which they are used The client\server architecture is being developed, and at the present the microcomputer enables to separate processing and data and to ensure the access to complicated peripheral devices in addition to personal peripheral devices (printing devices, memory).

Realized in such a way technological changes lead to the conception of the architecture of the groups of organizations which are geographically remote and functional organizations, businesses and institutes as a diagram, mostly a three-level one, which includes working stations, local servers and central servers. Such reorganization led at the turn of the 90s to considerable changes in the conception of information systems. This can serve as an example counterbalance the advance in the application of technologies in the educational system.

2.2. The reorganization of educational technologies

Quite early professional working in the field of education turned their attention to the possibilities which the technological changes listed above, give for the professional activities. Therefore, first of all the use of informatics in the field of information technologies has two different trends:

1. Education in the field of information technologies is regarded as a technological store of knowledge mainly for engineers but also as a mark of general education. The project «Informatics for everyone» («Informatique pour Tous») proclaimed in France in 1986, is significant in the view of the ambitions which a typical of some government in this age. Doubtless, the advantage of this approach is the wide-scale acquaintance of students and all educational community with microinformatics. It goes without saying, that providing education with this purpose in mind it was expected, that the software students were supplied with, should be nearly the same as that used at places of work. Great success was achieved in this field. Nevertheless, it should be mentioned that a recent examination, carried out in approximately a hundred computer classes 10 years later showed that the number of classes connected with the network is insufficient. The situation can partly be explained by the problems which emerged, according to the maintenance stuff, they can be divided in the following way: the management of hard disks, software support, virus problems; hardware maintenance, general support. It is no surprise that under the circumstances the mounting local networks in computer classes was given problems,

2. Informatics as a teaching tool; in the case informatics is regarded as a pedagogical tool in the same way as microinformatics was defined first and foremost as a personal means, and the use of technologies in teaching was mainly focused on individual training; the purpose of such tutoring was to provide information means to get access to information. Numerous programs were introduced for the purpose which helped to realize this conception also in developing software for education or improvement from school to university levels. This software has the names «Computer Education» («Enseignement Assisstée par Ordinateur» - EAO), «Courseware». This software is much more economical as compared with traditional methods of education and it enables to realize new applications while carrying out experiments (for instance, using modeling), and also to solve particular pedagogical problems without difficulties (these programs are more neutral than the teacher, the computer never gets tired and nervous and gives answers to questions, which are mostly asked repeatedly, in a calm manner, it ensures objective self-evaluation, etc.). However, the situation was the same as while teaching informatics (as well mentioned in 1): the means which were developed in the second half of 80s highlighted real technical difficulties connected with the introduction of informatics into education: the problems concerning the support of EAO software and its improvement; the compatibility of software and hardware; technical equipment for students, etc. The analysis of a set of

these problems helps one to arrive at the conclusion that the following approach is vital to integrate educational stations into the networks and to load educational materials into computers which makes it possible to change programs more easily and to better manage computer used by students. Parallel to the technological changes which take place when the client/server approach is used and the integration of networks into information systems, the questions arise connected with the organization of which in educational institutions. When discussing this problems one should take into account organizational and sociological changes which influence knowledge is passed to the general public which increasingly becomes the «client» of the educational system. In fact, if institutions providing general education, particularly primary and secondary, can ensure the variety in teaching and learning within one day, the educational centre seems to «disintegrate» more and more because of number of reasons:

- the transmission time to large industrial enterprises is becoming longer, thus increasing the time for institution, so some students refuse to continue learning;
- as there is the growing specialization in their departments universities make borders between them less rigid and increasingly call upon the teaching stuff and the centres where professionals work to cooperate;
- the period of learning is not limited by a short period, it lasts as long as one's career; it is more and more difficult to get education; the borders between the time for education and the time for work are becoming less clear;
- the economic situation makes businesses to increasingly participate in education; it is all the more necessary because the business itself take part in solving the education problems and in research, especially in technological areas;
- finally, education process is increasingly taking place in businesses or at one's place of work. In this conception the following survey presents interest, which was carried out by Ashridge Strategie Management Centre in 1993. It showed that the authorities at enterprises are involved in the education problems in 52 % of examined enterprises, the proportion being changed from 67% to 87% at multinational or private businesses. As the borders of educational institutions become less clear marked it is necessary that information and communication technologies should be coordinated in the form they are used in pedagogics, on the one hand, with new organizational and geographical structures of the education system and, on the other hand, with new users consisting of students and a new contingent.
- students who get education at home;
- students who get education at their places of work.

In conclusion, it is worth knowing that learning informatics and new communication technologies can be very useful for students if the technologies they are provided with are nearly the same as those they use in their jobs. In other words, new education technologies should be guided by technologies used by professionals and, consequently, to use communication networks and the client/server architecture to a greater extent. The experience gained by The National School of Arts and Crafts (le Conservatior National des Arts et Métiers - CNAM) can illustrate the afore said.

2.3. The example: The National School of Arts and Crafts

A special institute in the system of education in France, The National School of Arts and Crafts. Suggested that the students who had professional skills and often both worked in their particular area and studied, should do a course of studies to get a degree in engineering or economics or a degree of one of CNAM's institutes. By the decree worked out by Abbe Gregoir in 1794 under the name of the National School of Arts and Crafts there was founded the «park of machines, models, instruments, descriptions and books in all fields of arts and crafts», besides the institute was set up for people who had a teachers; the motto of the institute «Docet omnes» (it teachers all) symbolizes inspiration. 200 years later the CNAM found it necessary to set up a network of 53 joint centres which encompasses the whole country and provides learning through pedagogical management by qualified instructors; the process of teaching staff of each educational centre.

The growing audience which was the result of the increasing number of hearers, resulted in more clearly defined boundaries of the regions in which the territory was divided, the branch centres were founded for teleeducation; they made it possible to become closer to students' homes or their places of work. If in the middle of the diagram one placed educational centres and a detailed description of the courses thus the three-level structure could be created which could not but resemble the structure of the information system, considered above. This structure resembles the structures adopted by other similar institutions, such as the Open University or by some American educational institutions. What else should be done to transform the abstract technical structure into the real one? Two points should be emphasized:

- The distribution of pedagogical resources between the joint centres: the Internet is well adaptable to extension. In our opinion the extension of the network gives new opportunities to reduce the number of communication failures between the objects connected with the network.
- The choice should be made of the right industrial type to avoid making the same mistakes, receiving technical and educational reclamations as a result of such mistakes and to ensure long-term operation.

Finally, the pedagogics which uses new trends cannot disregard new opportunities offered by multimedia and networks, these approaches form industrial policy under the name «Information Highways».

3. NEW TECHNOLOGIES AND MODERN EDUCATION

3.1. The Internet phenomenon

Nowadays informatics can be separated neither from communication networks which ensure its effective support nor from multimedia which play an ever increasing role in devices providing the dialogue with the user (man-machine interface mode). The educational institution is not a business: students are not on the staff, they cannot be offered their own network; as a rule software and hardware available are different types.

The timely generalization of network technologies and their introduction which is more widely known as the Internet, is the source of a considerably advance in the introduction of new communication technologies in education. People in charge for new educational technologies notice, in particular, the following aspects:

• Superuniversal technologies which ensure great independence from suppliers and the opportunity to contact the systems in other offices, as well as the systems of various partners (administrations, businesses, etc.).

• Low costs of software for clients; it is important if one takes into account the number of working stations that should be provided with it and that the growing number of students will have access to the network from their homes.

• The system is open for functional expansion. The Internet, and especially WWW, are now being expanded by the software developers as user's basic variant, which can have supplements (devices of serial reading for video and audio devices, joint processing, animation, audioconferences, etc.) it will enable to make the standard interface regardless of the choice of suppliers.

• Should one believe that the Internet ought to replace something in any other network when choosing the communication structure for learning?

Far from that, especially if one realizes that networks, which ensure access for villages worldwide, are expensive and the quality of service they provide is variable; it depends on the country and even on the region where these networks are distributed. Approximately 34 % of American centres have at their disposal home computers; 70 % have access to the Internet or are serviced through telephone lines, but in France there is only 1 % of such users; it shows how different are the situation which are compared. Therefore, the preliminary analysis is necessary that aims to define what is available (technical means, network, people) depending on the type of the institution under consideration, its place in the system of education, its real pedagogic orientation. Looking at the example concerning the CNAM project mentioned earlier, we should single out the educational institutions and centres in Paris, which were connected through the Antenne to educational television. The data in the chart are the result of the brief examination. The chart shows the type of the network which is available for the user and the type of the user depending on the purpose.

Name of network	Teacher	Student	Engineer	Researcher	Service staff	Network type
Paris	Yes	Yes	Yes	Yes	Yes	Local network, Internet
CRA	Yes	Yes	Sometimes	Sometimes	Sometimes	Local network, Internet, RNIS, RTC
Antenne	Sometimes	Yes	No	No	No	Local network, RTC

The analysis will help to specify the technical means needed by each side and the type of communication with future partners. One should not neglect the cost of conjunctions and hesitate when choosing simple technologies because of an imperative need: telephone networks with the switchboard is an interesting choice if the objects which are to be connected cannot use expensive conjunctions and have no stuff for technical maintenance (it refers to the network Antenne in particular). The work done cannot be regarded complete without making the industrial choice which will enable to, fix standards and so to make it possible to pass from the conception stage to putting the model into practice. Such normative definition is necessary because of the following reasons:

• *Training provided for teachers.*

There is one key point. If not-a single teacher sought to get advice before he/she starts work, then the situation would be far from satisfactory in the transition period to the conception of education through electronic means: "computer literacy" still remains a privilege of some section of the teaching staff, and teachers of informatics are not always in the vanguard. The lack of any normative definition of the nature of support ensured makes any efficient training for teachers impossible. It results in the lack of experience, it makes impossible to see how efficient new methods of learning are and, what is doubtless more important, the teacher comes to depend on new technologies.

The main and invariable purpose of the technical support in this direction should be to ensure the teacher's independence - he should be free as much as possible from such concerns and realize what he can expect of technical means and in what way he can rely on professional assistance.

• *Training provided for students.*

The introduction of technical means should not entail extremely hard and special efforts on the part of learners. In a greater degree than the Internet itself the introduction of software for clients, which is widely used for the WWW users, is the source of hope: it is continuously and widely used in learning devices both in the Internet and in the Intranet; it enables to normalize the man-machine interface and to bring down the prices charged for training in particular technologies.

• *Succession in operation and maintenance of the systems.*

The industrial approach enables to economize and to ensure the application of specialized complexes of certain technologies in educational institutions. We can examine for instance one of the chosen variants, which was realized in practice when the whole territory was divided into regions using the CNAM project, and the centres chosen according to this project. One should notice the fact that the multimedia server is available in this case, its use presupposes in its turn the industrial choice of the means to develop and to receive image and sound as well as the normative choice of the means to put data in memory devices.

3.2. Advanced technological multimedia or the tool to develop pedagogical production

According to Gartner's group (le Gartner Group) studies in 1995 from the view point of multimedia developers, education is not the best field for the application of multimedia

- However, the question what is the multimedia remains the most difficult for professionals. Let us remind in short that the problem is how to use digital technologies to store and to transfer images, sounds and data. In what way can it influence learning and teaching? It is clear that the ability to store the set of videodata is the main advantage of multimedia because teaching can be conducted using gestures (middle-course technical training), there are teaching situations in which the manner of behavior is important (learning languages) or imparting knowledge based to a great extent on one's experience (study of commercial situations).
- When trying to define the configuration of multimedia working stations for education one faces the same difficulties as with information working stations mentioned earlier. Thus, since the late 80s it has become possible to develop independent working stations supplied with peripheral devices to read videoclips; they enable to read videosequences synchronized with the information of the given type, which makes it possible to transfer information on the subject taught and to test students' knowledge.
- The experiment carried out by the National Federation of Educational Equipment (la Federation Nationale de l'Equipement Electrique) in France gave a chance to see how good this approach was for training technical staff to mount control systems for ships. The experiences gained in such a way using the Dornomedia system shows that the pedagogical approach using multimedia should also involve the solution of organizational problems, including:
- rules of using software and hardware for the given pedagogical approach;
- the way to distribute devices for videodisks, the rules to get the license and the author's rights;
- to get an agreement of professionals to ensure training on the use of hardware and software;
- to make the park of information support uniform and to evaluate how suitable the local devices in use and their information infrastructure are;
- to provide tutors and to analyze the results of the students' progress.

It would be a mistake to believe that the replacement of videodisks by CD-ROM, and in the future by DVD, will change anything as regards the given problems. The types of information carriers can affect the cost of the information support but they will not help to solve the problems which must be solved, and the total cost depends largely on the adopted organization than on the types of information carriers.

The transformation of animation into digital form should lead, if for instance, one believes what G. Thery writes, to the reduction in. the production costs of animation; this reduction may amount to 200,000 - 1 min. Francs at present to 5,000 - 10,000 Francs in the near future. Nevertheless, even this cost remains exorbitant for education. Besides, it is not taken into account that the most essential problem is to develop a conception; it ensues that the total cost of production using CD-ROM, in which animation is only a small part, is between 500,000 and several million francs. At the present moment not a single educational institution can pay such a money and ensure the introduction of quality digital devices for the whole set of software. But after all these discourse the question can be asked whether they are really indispensible. Before one pursues the policy of costly education programs, one might consider another approach, which views the prospect of using multimedia in education in the future at another angle; this view takes into account the contribution of the teacher into the teaching process, the fact that most peripheral devices operating independently become soon antique is realized more clearly; this results in the need to coordinate the courses of study with the advanced in technical devices and economic situation. If one looks at the situation in which CD-ROM is a means of the information system, one can see that this approach should not influence the quality of material, which is a pedagogical support, in any way. The technical maintenance will develop without obstacles which arise when videodisks are used if the following points are taken into account:

- Additional memory devices operating independently should be used to store invariable data and on-line memory devices to store variable data and pedagogical data (evaluation of knowledge, conducting lessons, etc.)
- The role of the teacher as a mediator should be preserved not to break the connection of the student's working station and the teacher. This can be realized directly without mediators (see the example above, training technical staff - electricians) or by using networks serving as mediators, which provide simultaneous communication with servers containing variable data and establish communication with teachers.

Taking this into account, the experience that has been gained enables us to use the material which is now highly valued and which was established through TV education and when the multimedia were first used. Thus, the material gained when the electricians were taught can be used, provided it is corrected accordingly, and supplemented with new data. For instance, according to G. Théry the information stored about images which is at the disposal of the Institute of Sciences of Paris (Cité des Sciences de Paris) is estimated at 2,000 hours. Bearing this in mind it should be mentioned that the main obstacle in the development of multimedia educational material is not the lack of 'exhaustive' material, which is the common complaint, but the need to resent this material in pedagogical context on the one hand, and, especially, the need to edit this material by professionals in a better way than it is usually used to be done in educational courses using ordinary means to transfer information or when doing so through TV courses. One can only express regret that the games industry or informatics have the standard which is far from the standard to which our students have got accustomed; our Anglo-Saxon friends who coined the world «edutainment» (education and entertainment) had marked the hindrance, which we confronted, very clearly, it is not by chance that Microsoft with its product Encarta become the first seller in the world of encyclopedias. The requirement to take into account the cost of production, that is estimated in such approach, undoubtedly reflects the global vision of the problem. The need to meet the demand concerning quality leads to the problem of high qualification of the teaching staff who should master technologies, and thus in the substantiation of technical normative choices.

4. WHAT ARE THE RECOMMENDATIONS FOR THE PARTICULAR ACTIVITY?

The attempts to outline the range of tasks for informatics and new communication technologies in education were made based on the above mentioned. It is obvious that the garage owner should be a good driver, in the same way it is not obvious that the student who is well acquainted with information technologies and computer architecture should be a skillful user in the field of new technologies as well. Information technologies make a considerable part of the store of technological knowledge of the «real man/woman» of the 20th century, they share this privilege with the store of technological knowledge which form the present. Nevertheless, training to master these technologies should be conducted not creating illusions about its contribution to the better use of the technologies under consideration. First of all, as large part of the population as possible should master in a cultured manner the methods to search for information: we know many specialists in the theory of informatics who are unable to share their knowledge or to their knowledge into practice to search for information; on the contrary, it is not seldom that considerable contributions in the field of information technologies are made by the people who are not professionals in these areas (mathematicians, ergonomists, economists, etc.). Further we consider technology as the tool of renewed pedagogics, and also as a means which makes it possible to train our students better in using modern technologies.

The first obvious point, perhaps banal, should not be forgotten: it is necessary to define technological • situation on the basis of pedagogical situation but not vice versa. There is no one answer to the question about which technology should be used in education. Thus, one can choose among the following technologies.

• *Distance educational courses;* the means of group communication (audio- and video conferences) being widely used nowadays; when using technologies of this kind people mostly forget that initially these technologies were not developed especially for pedagogical purposes: videoretranslation of transparencies projected on the screen is much worse than in the case of a means of common use (the division of information supplement, information panel ...) in addition to a videoprogramme. Besides, the question can be asked whether the video program itself is less important than the separate use of the supplement, but it can affect teachers' habits and the marketing of designers.

• *Courses on request* when the students use teaching materials without the manager and for which World Wide Web technologies grant great opportunities.

• *Providing management and conducting lessons,* where managerial functions are realized; in case such technology is used it presupposes that there is a teacher for one group of students who are distributed at random over numerous geographic regions. There should be a complete store of various means (formulars, exchange of messages, common use of supplements, access to information servers...).

These are but a few examples by which we mean to illustrate the variety of situations which consequently need a variety of technologies, that have to be supplemented with numerous supporting communication networks; restrictions imposed by economic reasons should also be taken into account.

It is obvious that primary and secondary schools cannot compare with universities or engineering schools in this respect. Education authorities have not learnt to analyze and evaluate the policy pursued in education in technical and economic terms, the policy that the institute should choose and realize. They do not use the rich past experience which is available. In case of need high engineering bodies should be prepared to render help in conducting lessons by granting allowances. International researches can presumably be focused on repeated experiments carried out by institutions which have been offered to participate in the project to integrate their students into the network. First of all the results of these studies can be used to evaluate the policy which is to be realized. Besides, the joint data of these studies are necessary to take into consideration various social and economic conditions prevailing in the region for which the choice is made, the differences in the means available concerning the infrastructure of networks, microinformatics depending on the equipment available, the differences in the distribution of students ... The evaluation of the chosen projects from the pedagogical point of view is one of the most urgent tasks to avoid uneconomical use of investments in the period when they considerably increase. In fact, mutual exchange is becoming the international reality, there is no going against it. Besides, economical restrictions should also be taken into account. The cost of electronic equipment in education is sure to remain high, and it is increasingly true for a separate institution. Therefore, national and international cooperations choosing the direction of work should concentrate their efforts to determine the full content of the courses; however the cultural differences of such approach ought not to be underestimated the most difficult thing is to adapt multimedia products for international use (the translation of messages, transferred by voice, the peculiarities typical of the producer-country, historical and geographical variety of the material used, etc.). Research should be carried out to study these peculiarities, and it can be part of the work conducted by your institution.

Therefore, technical means should be introduced in accordance with economic and cultural features of each member of the project. Cultural peculiarities should be taken into consideration in the same way, as language peculiarities. In this case I speak about a very difficult problem, its research has not been supported with reliable means: computer translators, diacritic marks, alphabets of some countries, etc. At present the technological language is always English, the indication of which is the nature of some acronyms that I had to use earlier: CD-ROM for Compact Disk Read Only Memory (compact disks only for reading), DNS for Domain Name Server, SMTP for Simple Mail Transfer Protocol and others. The need to create the uniform technical vocabulary should not tempt us to simplify the cultural exchange: on the contrary, the dominating technologies ought to ensure the cultural variety at its highest. Under the circumstances, the variety of languages used by your organization should enable it to be the organizer to begin the research, and the promotion of the exchange of messages should help to enlarge your competence in these issues. In the near future the only means which remains is common languages used by people of different countries and the information means which present information not in the code, such as telecopies and, in the future, any multimedia. It is necessary that the regional centers should be set up, which would combine knowledge and experience so that in the future the means of communication could be used according to one's inherited linguistic requirements: it should be as convenient to use the Internet in French or Russian as it is in English. The use of the simplest ways of communications ought not to be overestimated: a lot of research is needed to solve pedagogical and organizational problems in tuition by correspondence and by television. Linguistic research should become part of the adopted policy, and the use of national and regional networks should be backed.

It is essential to take into account cultural differences if one seeks consent and active participation of those who are the main motive power of these activities - the teachers. The use of new technical devices inevitably change working habits, this situation and the added change in teachers' traditional approaches can doom this operation to failure. To avoid this conflict one should try to make the teachers want to master electronic means and means creating support materials; it means that at present a comprehensive program of teachers' training is needed almost in all institutions that bear a relation to it, even if the purposes set in the programs differ on a regional or national scales.

At present the program of teachers' and students' training is one of the main factors when introducing informatics in education. This training should be viewed in two aspects:

• training of general public to use technical means to get access to information, which will determine their whole active life;

• passing specific knowledge to students and teaching staff on those technical devices, which are to be used in the process of training.

To minimize the economical and organizational difficulties of the second aspect it should be brought as close to the first aspect - which has no bounds - as possible. It should be reiterated, that the choice made on the second aspect should be as much «industrial» as possible and reflect the situation with technological maintenance, one ought not to pay too much attention to innovations, except the pedagogical ones; the standards accepted by the executives should be general and in line with approximate standards set at the project's design stage. Doubtless the implementation of the set of chosen projects would lead to the economy of funds; but such set can hardly be coordinated on the international level: regional and national economic policy is sure to provide the decisive influence on this approach. Nevertheless, it is advisable that the international coordination should be carried out, which aims at the transfer of pedagogical support to various technological platforms in the case, when the differences are undesirable, which result in a set of pedagogical approaches of those countries that are poorly equipped in industrial terms as compared with the countries that are technologically developed in the areas of informatics and teleprocessing. Obviously, the diversity of the problems exceeds the potentialities of people who are responsible for the introduction of new technologies in educational institutions. Those at the head of the projects do not have the results of research and cannot rely on those who carry out research but have been giving wrong answers up to now and who are poorly organized. Obviously, the help should be given to set up centers, which are to be competent in the area of educational technologies (consultation societies, inside administrative support services, etc.). The international exchange of information between those centers will enable to pass on technologies from the countries having greater experience to the countries having less experience. This efforts cannot be only reduced to the introduction of the systems: the introduction of local networks in the institutes, their connection to the Internet, the possibility of connection of educational network to the network of enterprises guarantees a better service for the users, simplifies the maintenance of communications and ensures better service. The joint networks of students' working stations is also desirable from two points of view, which are important for our practical workers:

- joining up into the network (Network Computer) if it is realized will enable to ensure the better management of the configuration and the technical support of users at lower costs;
- if the question is settled about the joining of establishments (particularly enterprises) to the education system it will enable to learn more about students' life and, especially, the need of continuous training during the whole career: training is known to be more efficient if it is part of the process, which aims at the acquisition of knowledge at the time when its need is conditioned by an activity. Education can be provided «just in time» only through the educational communication network open for professionals in the field of economics.

Therefore, meeting these two objectives confirms the benefits of joining up into a network of set of technological means of education using both local networks (LAN) and distributed networks (WAN). The policy of extension of the Internet and information highways gives, in this case, a good chance to attract experts in the field of education: one has to make sure that the educational section is systematically included in the projects, and this section is available for all experts in pedagogics, engineers and economists. Finally, one can mention a low quality of methodotogical research on the application of new technical means as compared with the teaching objectives according to the information from the experts in different countries who were commissioned to work in the field of new educational technologies there is a tendency which indicates that these technologies do not result in a considerable difference in the efficiency of traditional courses and those which use new technologies. These results should be specified, and their methodological framework should be set in such a way as to give the opportunity to compare at the international level using general methodology. In conclusion, I believe that the head of administration should be in the center of the information system in all our activities, and the commercial manager at the head of managing of automatization technologies in trading businesses. This approach is similar to that which was suggested in the introduction dealing with another area and in which the patient was in the center of the hospital information system. The education system ought to begin to listen to its «patients». The research carried out by SORRES in France in 1991 among educated adults showed that the expected advantages in home education through multimedia are mainly centered around the factor of time: the opportunity to set one's own pace of work, to schedule one's time ... In its turn, the study of lessons using Teleservices in France carried out by Centre Eutelis found out the factor of pace: when asked about preferences concerning the place of learning students gave answers shown below:

Location of place giving access to teleinformation	Choice
At home	27%
Local collective stations	27%
Educational centers	24%
Establishments	21%
No answer	1%

New technologies, which combine mass technologies and professional technologies, help tyo divide our environment: interactive television will be available in every home in the form of a box containing both the memory and the processing device, satellite networks will ensure the worldwide access to information even on a larger scale. Our duty is to define the place of these technologies and to make sure that those in charge of the electronic programs of interactive television will allow to transmit the contents of the pedagogical support which we are going to suggest.

In the situation when the unity of time and action is broken the role of the teacher as the distributor of knowledge will be transformed into the role of. «engineer» of knowledge, who organizes the access to electronic means of information for students. It is necessary to prepare the teacher to play this new role. The definition of the teacher's role is the main subject of our discussion. This role ought to be recognized not only when he/she gives lessons, but when a time consuming job of creating pedagogical computer support is carried out, which results in the reduction of time of the teacher's presence at the lessons. The institute of education should be provided with funds and be competent, this will enable it to realize its pedagogical and technical project at a high level. But it should be empherized that even in the light of the afore said, it is the student who should be the focus of technical education. We must concentrate our efforts to meet his requirements.

Commission I

INTERFACE TO INTERACTIVITY: TECHNOLOGIES AND TECHNIQUES

Sandra Wills

EDUCATIONAL MEDIA SERVICES
UNIVERSITY OF WOLLONGONG (AUSTRALIA)

ABSTRACT

What makes a technology interactive? Is radio interactive? Television? What about books, lectures, conference sessions? Is interactive multimedia really interactive? A TECHNOLOGY is not in itself interactive - it is the INTERFACE we design for it that is interactive. What makes an interface interactive?

1. INTERACTIVITY

Each new advance in educational technologies heralds new possibilities, often before fully realising the potential of the previous technology. Interactive multimedia promises interactivity. But have we never had interactivity before? Is a book not an interactive experience? Does a lecture have to be only a passive experience?

As Kristina Hooper Woolsey (1988) states:

"Anyone who has looked at run-of-the-mill computer software or branching videodiscs that continually interrupt the viewer with multitudes of unappealing choices understands that interactivity is not a sufficient condition for a good experience. Similarly, those of us who have sat on the edge of our seats in lecture halls and theaters, enjoying a nonpassive experience even though we have no control over outcomes or opportunity for any

interaction, must acknowledge that there is really something to the crafts of rhetoric and storytelling" (p.320).

Very often it is the skill of the designer that guarantees its interactivity, whether that technology be a book, a lecture, a video, or a CD-ROM. Interactivity is not necessarily inherent in the technology itself.

Multimedia marketers would have us believe that the ability to point and click is a far more interactive experience than the ability to turn pages in a book. Books do not have to be, and in fact often never have been, only used for linear presentation. They, like multimedia, can provide information in chunks and provide the reader with the ability to navigate in any direction - via the contents page and an index. If the book as a format was not such a wondrous thing, then why do so many interactive multimedia developers imitate the book as an interface metaphor?

This is not to say that the older technologies are perfect. Design of hypermedia systems can lead to improvements in the design of older technologies. Ted Nelson's *Xanadu* system was an early hypertext system, pre-dating HyperCard by over ten years. His book, *Computer Lib: Dream Machine*, challenged the format of the traditional print medium twenty years ago.

Another example is Apple's book *Demystifying Multimedia* (1993). This book uses **bold** to imply links as does any hypermedia document, but instead of being able to click the bold to go to that link, the page numbers of the link are in brackets after the bold. The book is also organised so that each page is a chunk in its own right, and can be read in whichever order takes the reader's fancy, or in which order the reader has need, more like a magazine than a textbook.

We need to be clear as to what we mean by the word 'interactive'. It is being promulgated as a necessary condition of an effective learning environment. However, interactivity goes beyond mere point and click. An analysis of the different types of interactive experience is provided in a previous paper "Beyond Browsing: Making Interactive Multimedia Interactive", Wills (1994). It may variously mean: simple electronic page turning, hierarchical menu choices, point and click browsing systems, or testing and tutoring on black and white facts. However it could more aptly describe active environments that engage the learner in a challenge or mission based on manipulating the information contained in the system. Interaction may be better defined as *engagement.*

2. INTERFACES

2.1. Guides

One of the best ways of engaging students in a task is through the personality and enthusiasm of the teacher. Designers of educational interactive multimedia can engage users by personalising their interfaces. Some use guides, wizards, and agents as techniques for "characterising the interface" (Oren et al, 1992).

Two products I've designed, utilise guides as a technique:

- Interactive Handbook and
- Interactive Proceedings.

The *Interactive Proceedings* was developed for an IFIP Working Conference on Interactive Multimedia In University Education: Designing for. Change in Teaching and Learning, at The University of Melbourne in 1994 (Beattie, McNaught & Wills).

Prior to that, in 1993, we set out to design an interactive version of The University of Melbourne's Undergraduate Handbook Volume 1. The 60 page colour handbook is distributed to prospective students and contains information about the university and its courses. The design team treated the task as building a graphical user interface on top of the 30,000 words of descriptive prose in the handbook.

One solution to the problem of providing interesting navigation through 30,000 words of prose was to humanise the handbook by providing eight university students from a range of courses and backgrounds to act as young guides to the university. Audio grabs from the guides give insight to university life from their personal perspective and add humour to what was probably a dry publication. The guides offer pathways into areas that the interactor might not otherwise have explored.

Oren et al (1992) used guides for a similar purpose with an American history database prototyped at Apple in 1989:

«It has been widely noted that hypertext systems are characterised by user disorientation, or "getting lost" while attempting to find a way among the myriad connected documents and links... The hypertext author's purpose may be to provide an educational experience, but the cognitive load posed by navigating among the various items may be so great that the user has little energy left for absorbing the content... We began looking at the use of characters and the human figure to suggest a storylike structure and get the user involved in a search for relationships among the various pieces of information... Guides first appeared in the form of travel agents... [Then] we decided to change the interface so that it... all looked like part of the historical period. We wanted to add visual richness, provide a context, and seduce users into the mood of the database from the start" (pp.367 - 371).

They then researched how best to represent the guides: as icons, as cartoon figures, or as photographs/video using actors. They observed interesting differences in users' reactions, noting that even with iconic guides, users assumed characterisation although the designers had not explicitly set out to develop them as characters.

"We have found value in the deliberate personification of the interface, in introducing the conventions of storytelling, point of view, and character into the computing milieu. This seems to result in engagement, projection, and suspension of disbelief on the part of the users. Children often assume educational material is objective and comprehensive, but in fact any encyclopedia has a particular perspective... Guides suggest a natural way to present multiple voices and points of view" (p.376 - 7).

In creating guides for the Interactive Handbook, we chose an alternative not available to the historical database designers - we used real people. The Schools Liaison Officers often remark that students are the university's best sales vehicle. The implications that follow from the design choice of real students versus invented graphical characters include the need to:

- update as the students grow older/change interests/change hairstyles;
- write scripts in keeping with the real students character;
- train the students how to perform enthusiastic or humorous 30 second grabs!

A number of other universities have now prepared CD-ROMs for prospective students: ELVIS from WA, Studylink from Wollongong. SYDNEY-ROM from University of Sydney, and the University of Waikato Student Recruitment Kiosk. However, to my knowledge, none have used guides as an interface.

The University of Wollongong Education Faculty's

Exploring River Nardoo, a soon-to-be-released ecological simulation, following the success of *Investigating Lake Illuka,* makes excellent use of guides. The guides are an interesting hybrid of video actors and hand-drawn graphics.

Guides as a technique in the *Interactive Handbook* was well received and achieved the goal of taking the interactors into parts of university life that they might not have otherwise seen. However one of the evaluating students said in their thinking aloud video: "It is an unfulfilled promise - it raises our expectations and fails to deliver". They wanted a conversation with the guides! The design team felt that the CD-ROM needed additional features to enhance its interactivity, for example, an adventure game or puzzle to solve; interviews with graduates; and video clips of the university experience such as lectures, tutorials, field trips, laboratories, and the social scene.

The capability to personalise information and humanise the interface with guides is something well handled by interactive multimedia and not as well handled by books. However, this doesn't mean that books cannot do it. The printed handbook went part way towards reflecting our human interface - it provided a snapshot and thumbnail interview with each of the same students.

2.2. Text

Another reason why the *Interactive Handbook* prototype is an "unfulfilled promise" is the disparity between the professionalism of the graphical user interface and the amateurism of the textual information. The design team came to understand that text does not translate directly from book form to multimedia form. The large amounts of descriptive text in the handbook needed re-purposing for the screen. Text in multimedia publications needs to be treated in ways more akin to text in television and video productions, that is, use of bold concise headlines and bullet points. [See previous paper, The Book is Dead - Long Live the Book, (Wills and Swart, 1994)].

Our multimedia publication hadn't replaced the *existing* print-based handbook. Text is very well served by print technology. In hindsight, the multimedia publication has to serve a different purpose from the print-based handbook.

Menu choices in the *Interactive Handbook* structure reflected the print-based handbook structure therefore the publication did not address aspects of university life that multimedia capacities could have dealt with if we had designed the content from scratch rather than rooting it in the existing delivery format.

The process of designing, evaluating and reflecting on the nature of the *Interactive Handbook* has forced a re-think of the function and format of the traditional handbook, and other University promotional products such as videos, in recognition that each medium has unique characteristics that could be better harnessed to complement each other rather than compete.

Oren et al noted similar concerns with their historical database:

"... *in designing an interface to a textual database, we have found that the writing style adapted to the print medium is not optimal for the computing medium. This is a warning that there may be sharp limits to the notion of "repurposing", that is moving existing content to a new medium by simple format conversion... Because the text base was fixed, expanding the guide's role in the video version required adding content in the video sequences. The result is that the richness of the video image currently dominates the user's experience. The text appears flat and boring in comparison" (p. 378).*

3. INTERACTIVE INTERFACES FOR CONFERENCES

Participation in a conference is an interactive experience not matched by the traditional print-based proceedings the rest of the world gets to see. The print-based proceedings produced as an outcome of a conference is a non-interactive experience. In fact the book we see published is not a "proceedings". It does not show the totality of the conference process.

An aim in deciding to design an interactive proceedings for the IFIP conference was to bring closer together the conference process and the conference outcome. The team set out to produce an experience for the interactor that reflects the interactive nature of such conferences; to capture the atmosphere and the progressive development of the debate and discussion; to enable the interactor to see and hear the personality of the authors via video and audio.

Editors of conference proceedings in general take one of two routes for organising the print-based proceedings: alphabetical order of authors or an order that reflects the conference timetable. An interactive proceedings allows the interactor to approach the papers from multiple angles not just those structured by the editors. In this *Interactive Proceedings,* multiple perspectives are provided via the Theme Roundabout, the Guided Tours, the Expo Hall, the Souvenir Stand and the Library. Hypermedia links provide alternative perspectives not usually possible in a print-based proceedings other than via a comprehensive index.

The Theme Roundabout is a means for authors to position their papers against each of the three conference themes (Design, Implementation, Evaluation) whereas the conference timetable allows positioning only under one theme dictated by the programme chair.

The Expo Hall was designed to contain most multimedia demonstrations used at the conference. This feature is a quantum leap on print-based proceedings, which merely talk about multimedia instead of doing multimedia. The Expo Hall allows review and reflection on demonstrations that went all-too-fast in the confines of a conference timetable. Print might be a good medium for *discussing* multimedia but it is a poor medium for *demonstrating* multimedia.

The Library houses the traditional papers in alphabetical order of author (as does the print-based proceedings) and provides fast scrolling, hypermedia links, and audio comment from each author.

The Souvenir Stand supplies major elements of conferencing that are missing from print-based proceedings:

- networking and
- touristing.

It contains formal and informal snapshots of the conference including social events; business cards; home video of Melbourne sights; and postcards.

The officially designated conference Reflectors, and selected conference participants recorded Guided Tours while at the conference to reflect and link aspects of the papers that were important from their personal or institutional perspective. For the interactor, these Guided Tours provide comments from discussion sessions and links to papers via audio and video clips recorded live at the conference.

There is also a facility ("U-Drive") for the interactor to record their own tour using the presentation-maker which bookmarks their selection of screens and attaches their voice comments. Like marginal scribbles in a print-based proceedings, this "U-Drive" facility enables the interactor to tailor a multimedia report of the proceedings. Tools such as these, which allow the interactor to construct, manipulate and add value to pre-prepared published content, provide higher levels of interactivity than a print-based proceedings.

Another aspect of the product design is the flavour and style of the graphics and interface. Part of attending any conference is the humour, repartee and social events. It is not just the academic content that one remembers but the interaction with people. Traditional print-based proceedings are stuck in a formula that do not reflect that atmosphere of friendliness. It was our aim to produce an interface with humour - it should make you smile.

Did we succeed with our interface techniques for interactive multimedia? Not entirely. As Brian Harvey says in his guided tour in the *Interactive Proceedings:*

"So-called interactive multimedia makes a promise it cannot keep. The interaction is very far from being a conversation. We experts get to do the talking while you users get to choose which expert to listen to."

4. CONCLUSION

Some of the features described could in fact be utilised in the design of print-based proceedings which are, unfortunately, usually based on tried and true, but boring, formulas. There is a danger that the design of an interactive publication can be tied too closely to the print-based medium with which it is associated. The interactive publication should challenge the design of the traditional academic proceedings. Once a paradigm shift has been achieved, the design of an interactive publication can inform on the design of its associated print publication, as occurred with the *Interactive Handbook* described earlier.

Conference proceedings are now being published on the network, in fact many assume that the web is all we need now. *AUSWEB95* is an excellent example of a multiplatform proceedings - it's on the web, in print, and on CD-ROM. So is *OZCHI195. Teleteaching 96, a* virtual conference later this year, will only publish on the web and CD-ROM, bypassing print altogether.

However we still have much thinking to do about the value of each platform, about reassessing the role and best features of each technology, and using them appropriately. Currently they are too closely tied, copying each other in form and content. The learning need, or information need, is not likely to be best addressed by a sole technology, nor is it cost effective to publish on all platforms. A combination of appropriate technologies seems more sensible - "multimedia" in the original use of the word, meaning multiple forms of media.

As the bandwidth of networks increases, the capacity to publish multimedia conference proceedings, and university handbooks, will become the norm. The powerful combination of multimedia publishing and network publishing will be a paradigm shift in conferencing and publishing. The technologies are there, but do we yet understand the techniques for guaranteeing the interactor a truly interactive experience?

IS TECHNOLOGY THE ANSWER FOR OUR CHANGING EDUCATIONAL NEEDS? YES, BUT ONLY IF...

Hartmut Grebe

CONSULTANT (GERMANY)

LEARNING TECHNOLOGY AT A CROSS-ROADS

The "yes" in the title of my talk suggests a generally positive and optimistic outlook, which is tinged, however, with a good dose of scepticism. In the course of my talk I will fill in the dots and elaborate on this scepticism.

The argument which lies behind the thesis implied by the title is that Learning Technology or, more elaborately, Informatics for Education and Training is at a critical juncture from where one road can easily lead to decline and disrepute of the field if we do not actively set the direction of development. To be sure, learning technology is here to stay. The necessities that will force us to use some form, or forms, of learning technology are driven by global development trends that nobody can reverse.

However, we might easily see a severe setback of the field by a decade or more as funds could dry up if viability is not convincingly demonstrated. We might also see the field go off in directions we won't like. We might be confronted with the development of serious negative side effects as in the case of public television, a technology with a still unexploded potential for mankind.

EDUCATION AND TRAINING TODAY

What are the trends that have created an urgent need for the employment of learning technology? These trends have been described at length at countless occasions for a number of years. I will only briefly touch upon them to create a frame of reference.

In the course of this century we have seen a breathtaking branching out and subdivision of disciplines into a bewildering panoply of fields and specialities. The scientific approach to interpreting and coping with the world around us, pioneered during the renaissance, set off a development that brought us an avalanche of knowledge that needed to be managed. However, science and technology are not the only culprits. The forces of the free market system worked toward an increasing flood of new products and enormously enhanced productivity requiring new skills and new areas of knowledge.

With the proliferation of products and the differentiation of production methods, the structures for keeping the whole system running became ever more complex and interdependence among people increased. This in turn required new skills for managing an emerging web of new interdependencies. Non-professional skills from filing complicated tax returns to navigating in a maze of contracts, laws and regulations, to handling intricate machinery of transportation and telecommunication needed to be mastered by everyone.

When high-performance transportation and telecommunication systems created the opportunity to expand a persons net of interrelations over great distances, interdependence received another boost requiring additional skills to cope.

CONSEQUENCES FOR OUR EDUCATIONAL SYSTEMS

The consequences for our educational systems can be summed up as follows:

- Accelerating change in nearly every aspect of human life and the need to cope in an increasingly complex society necessitate the acquisition of skills the teaching of which overtaxes the traditional educational institutions. Methods with improved didactic efficiency are required.
- The distinction between pure training phases and life-long training paralleling one's work life becomes fluid. As opposed to a one-time formal training period concluded with a degree, there will be repeated training phases. Between these training phases, there will have to be training accompanying a person's daily work. When training has to be integrated into a work schedule, systems for Open and Flexible Learning are needed which are based on computer, television and telecommunication technology.
- Traditional demarcation lines between individual disciplines dissolve as disciplines penetrate each other creating new subdivision. Coping with the ensuing checkerboard of specialities requires new delivery systems for education and training.
- The dividing line between higher education and vocational training is becoming fuzzy and will continue to become more permeable. While American universities have always had an eye on the immediate usefulness of the skills they teach, universities in other parts of the world, certainly in Europe, need to strike a new balance between equipping their students with a solid theoretical base and teaching them skills that are immediately applicable.
- The differences between formal university enrolment and learning opportunities offered to the public at large are becoming less pronounced as universities need to be more practice-oriented and the quality of training through commercial course providers increases.
- As technology advances and new products enter the market while others become obsolete, economic dislocations will continue to cause unemployment of major proportions unless they can be countermanded by making the adjustment process quicker and more efficient. The unemployed quickly need to be made employable again by new industries through a responsive, flexible and differentiated restoring system. Such a system can only be built with learning technology. The reduction of structural unemployment requires learning that is more market-oriented,
- With the internationalization of markets,

companies, to stay competitive, need to follow the principles of Lean Management and outsource services such as training. Training services are increasingly supplied by course providers and training brokers who act as wholesalers of education and training. For this market to function smoothly, learning technology is indispensable.

- Overcoming cultural barriers on the road to international cooperation is facilitated by cross-border learning opportunities. Through technology-supported distance learning, immediate access to sources of learning which originate in other countries becomes possible.
- In this new situation our traditional institutions of education and training, especially the universities, need to set up structures through which they can respond faster in an environment in which the training needs change at an ever increasing pace. Coping with these challenges requires the development of a diversified and effective learning technology and the adaptation of content to the new media. The universities need to cover new ground if they want to avoid being relegated to a diminished role.

OPEN AND FLEXIBLE DISTANCE LEARNING

All these phenomena and trends create an urgent need for the development of Open and Flexible Learning Systems which will be largely, but not exclusively, systems for Distance Learning. The major qualities of Openness and Flexibility will be independence of location and time. Learning presupposes interaction of some sort. Where the learner interacts with a medium rather than a person, e.g. with a multi-media learning program on a CD-ROM, the technology allows him to be truly independent of time and location. With the appropriate technology the learner can then learn where and when he or she chooses. When the learner interacts with a person, even if this interaction is delivered by means of telecommunication, the learner will be subject to certain time constraints as he needs to be co-ordinated with the distant instructor.

The learner still enjoys the more important benefit of flexibility, namely the independence of location. If education and training is relieved of geographical constraints, this will also at least loosen time constraints since overall co-ordination of instructors and learners becomes more flexible.

In any case, technology is needed to bring the opportunity for learning to the learner's home and workplace. Technology is also needed to give the learner access to rare experts and specialists at distant places. Another expectation from technology is a substantial improvement in didactic efficiency through multi-media tools such as video sequences, animation's, pictures, graphs, simulations, audio clips etc. With the possibility of wider distribution through technology, a much more careful preparation of content becomes affordable.

EXPECTATIONS FROM INFORMATICS

The needs are straightforward and the means by which to meet these needs seem, at first glance, straightforward, too. However, throughout the history of the digital computer, informatics applications with a socio-psychological component have been accompanied by the persistent temptation to expect technical solutions to non-technical problems that are not amenable to the algorithmic approaches of the computer world.

A fascinated public has repeatedly placed great faith in computer technology to solve societal problems, only to be disappointed when the hoped-for benefits fell far short of expectations.

Over the decades a certain pattern has evolved. First, deficiencies are seen in some area of human activity. Computer technology seems to have the tools to remedy these deficiencies. Straightforward solutions are attempted. These solutions either fall short of expectations or fail totally. The situation forces a deeper analysis of the activity to be improved. The analysis then reveals that the activity depends on a host of non-obvious factors that were not, or not sufficiently, taken into account when the activity was changed, seemingly improved, through the introduction of technology.

AN EARLY WARNING

An early sobering experience and instructive example was the development of computer-based information systems. Their development was the first endeavour in which the complexity and interdisciplinary nature of a field and the meshing of the formal-algorithmic and the socio-psychological spheres were underestimated challenges.

The field of information systems was also opened up with high expectations and enthusiasm for the quick establishment of distinct theories and methodologies and for the rapid alleviation of a serious societal predicament.

After a period of optimism and intriguing visions of the future, the field of information systems went into a severe slump in the early seventies when funds dried up after disappointing performance in terms of user acceptance of elegantly designed and prima facie attractive systems. Only after a long hiatus, the field recovered slowly with initially quite unspectacular applications based on practical experience and scaled-down expectations.

When information-seeking behaviour was analyzed, it became apparent that far too much had been expected from the algorithmic penetration of this complex activity. It was realized that the way information is sought determines the information found and thus is an inseparable part of an intellectual accomplishment that cannot be expected to be automated. Criteria by which information could be judged relevant, namely a relevance measure, could not be satisfactorily defined and statistically stabilized. The unsatisfactory performance of information system spawned quite a bit of research into information flow in science and technology. It turned out that the essential information flow that determines the course of science was much more determined by personal contacts and exchanges, many of them adhoc, spontaneous and seemingly unplanned, than by the formal mechanisms of congresses, publishing and archiving.

When the original ambitions for remedying a general societal problem were given up, the field of computer-based information systems recovered slowly and in time prospered more healthily. Awareness had grown that the patterns of a human activity that has evolved over many years, if not centuries, creates an extremely complicated web the performance of which diminishes if it is perturbed by too radical change.

A LESSON LEARNT

The lesson learnt from the information system debacle was the stipulation that an activity should only be "computerized" if the structures in which the activity is conducted are well understood and have reached a certain degree of formalization before computers are employed. These structures should then be precisely mapped onto computer algorithms before they are honed for higher performance exploiting the specific capabilities of the computer. The field of information systems got a new start from very practical applications like the airline reservation systems. These systems had matured with paper, pencil and file cards, and all structures of information flow and processing were in place before computers were used. From such pragmatic and comparatively unambiguous application, the field evolved in small steps to more sophisticated functions.

We must ask ourselves if such lessons do not apply to the field of informatics for education and training as well.

HOW MUCH IS TELE-PRESENCE REAL?

Before we will take a look at specific learning technologies, let's consider how the learning process will be altered by learning technology. Generally speaking, there is less interaction with people if we employ technology. Either the interaction with the instructor/teacher is reduced if his or her presence is only a tele-presence, or there is no interaction with a person at alt as in the case of Computer-Based Instruction. In tele-presence we convey, by technical means, only certain aspects of the instructor/teacher, the ones we think are important.

When we reduce, in some way, the presence of an instructor, we reduce the bandwidth of his or her personality, figuratively speaking. One reason, of course, is the limited technical bandwidth that is available to us. The question arises: Would we know what to convey had we unlimited bandwidth at our disposal. I think we must say that we don't know precisely how much we are losing through telepresence.

Even if we transform the teacher from an instructor to a guide, facilitator, or collaborator, we don't know how much a teacher's presence is essential in a specific setting. This will depend, of course, on the student group, the subject, the cultural environment and other factors. However, learning is intricately interwoven with identifying with a model and being motivated and encouraged by the example of a person representing or living the subject to be conveyed.

HOW IMPORTANT IS A ROLE MODEL IN LEARNING?

It is hard to find words to convey the full breadth of the phenomenon I want to describe. Not only in learning, but in other fields as well, we have a tendency to underestimate the extent to which the essence of an interaction between people is mediated by deeper personality traits which the offering person has and emanates. These deeper personality traits have to do with very general qualities that are hard to capture with language. You could say it is cognitive style, i.e. the way the person sees and interprets the world, but more than that, it is the way the person is in the world and his basic attitudes toward it. To describe what I mean, let me digress for a moment to other fields. Take psychotherapy. There are many schools of thought about how therapy works and what it is that causes a person to heal, in fact what healing in the therapeutic sense actually is. Based on these different schools of thought or theories, there are innumerable psychotherapies competing with one another for being the right method based on the right theory.

Comparative studies show, though, that the success of therapy is much more determined by the qualities of the therapist than by the therapeutic method. Such qualities are hard to define. It is something like the credible example of another connection to the world, to people, to mankind. And it is the capability to "infect" the other person with such a different basic attitude.

These attitudes are so basic that they also are hard to describe with words. How can one describe what in religion is meant by the term "Trust in God"? You don't even need to be a religious person to experience that kind of stance in life. Many people have this basic attitude without identifying with this phrase. Such a basic disposition toward life is not conveyed by ever so many text readings. The way people get it is by being "infected" by another person at some point in their lives, the fortunate ones in their childhood by their parents.

TELE-PRESENCE IN LEARNING

My claim is that such mechanisms play a stronger role in learning than is generally accepted. As these mechanisms are not easily amenable to scientific study, our pedagogical research and body of knowledge is dominated by other phenomena, those which are scientifically and statistically manageable.

I am not saying that we need as much physical presence in the learning process as we generally have today. There are many autodidacts who are capable of going through extended courses of study without interaction with an instructor, teacher, or professor. There are many subjects that can be taught partially or in to without human interaction. Other parameters are age and cultural context, or plainly the availability of instructors.

However, if we do not take the importance of role models into account, we are in danger of losing an important element of teaching and learning. I have not even mentioned the more general problem of the deterioration and depletion of social interaction that modern society is plagued by. Computer technology, Computer-Supported Co-operative Work (CSCW), and telepresence certainly intensify this trend.

Students in traditional distance learning have complained about social isolation for a long time. In this case, tele-presence will actually relieve social isolation to some extent. The important part is that planners of learning technology be sensitive to social needs and provide for a mix of learning modes and facilities to satisfy these social needs in a reasonable way.

COLLABORATIVE LEARNING

So far I have talked about interaction between teacher and student or students. Similar considerations apply for interaction between and among students in a classroom setting when the classroom is geographically distributed with the help of information and telecommunication tools.

Learning and motivation for learning in a collaborative setting is just as much influenced by a multitude of factors and parameters, some obvious and easily accessible to analysis and emulation, others subtle and hidden in a web of semiconscious or subconscious dynamics. What prompts interactions in a classroom setting and how these interactions exert an influence on motivation, attention, intellectual engagement, and retention seems relatively accessible to analysis at first sight, but is actually determined to a considerable degree by complex group dynamics and by complicated signal exchanges between participants.

To have these interactions pass through computers and telecommunication equipment will change the character and the effects of the interactions. A considerable amount of filtering will take place. Simultaneous and quazisimultaneous events will have to be sequenced. Some stimuli will be cut off. New phenomena will crop up.

At this point, it is unknown whether the character of the interactions will be sufficiently retained to induce participants to look for the same benefits that they are used to from traditional settings, or whether the character of the interactions will change into something new that might be less or, possibly, more helpful in the learning process. A novel character of educational interaction might call for new avenues of optimization that might lead into other directions than those suggested by the traditional type of interactions.

My thesis is that we don't know beforehand how much human interaction we need in a particular instance. This is as much an unpalatable factor in developing learning technology as the peculiarities of human information seeking behaviour were in building computer-based information systems. For every educational setting we have to develop a balanced mix between computer-supported self-learning (e.g. by learning programs), synchronous and asynchronous collaborative learning (e.g. through computer-video connections to tutors and email-type exchanges), and phases of physical presence.

What we need, therefore, are modular, scaleable systems of learning technology which can be tailored to a specific scenario.

THE TOOLS OF TELE-LEARNING

What kind of information and telecommunication tools are available to us for education and training?

We can, of course, use telecommunication and technology in many simple and straightforward ways for learning, be it by receiving instructions over the phone, getting learning material by fax, or viewing a television program or video tape. When we speak of learning technology, though, the following tools and technologies come to mind:

• *Without inter-personal interaction* (network-based or as stand-alone applications):

— CBT (Computer-Based Training), i.e. learning programs from simple page-turning text-based courseware to sophisticated interactive multi-media applications on CD-ROMs.

— Instructional video tapes or TV broadcasts Interactive video disks.

— Access to educational data bases.

— With asynchronous inter-personal interaction (deferred-time communication):

— E-mail.

— Computer conferencing.

• With synchronous inter-personal interaction:

— Relay Chat (*real-time textual exchanges*).

— Computer video via small-band ISDN Interactive television, one-way television - two-way audio.

— Interactive television, two-way video - two-way audio, both over multiple ISDN channels.

— Interactive television, one-way television.

— ISDN video back channels.

To satisfy the needs of a particular situation, these tools and technologies can be combined in a wide variety of ways. Thus a learning technology can be tailored to meet the requirements of a specific learner environment.

Such specific requirements can be:

- The availability of transmission media or, possibly, one specific transmission medium (e.g. telephone, ISDN, TV).
- The familiarity and experience of the learner community with a particular technology.
- The kind of equipment that is already in place.
- The funding situation.
- The form in which high-quality content is available.

AN EXAMPLE: THE ECOLE SYSTEM

In the DELTA and TELEMATICS Programmes of the European Union several systems combining various tools were developed. I'll use the ECOLE system as an example. ECOLE was developed under the assumption that one specific transmission medium would be available to build a transmission network for a learner community, namely ISDN. So the question became: What kind of tools can you combine to make full use of ISDN as a transmission medium. The result was what I call an "ISDN-based Comprehensive Learner Environment".

ECOLE would typically serve a distributed home learner community where each learner has a PC with video capability and an ISDN connection. All he or she had to do in addition was to load the ECOLE software. The goal was to give each learner a comprehensive set of tools that would allow him to participate, at a distance, in a course of study pretty much as though he would be enrolled in a university or other educational institution and be physically present. The video capability with the support of an appropriate user interface was to set up distributed classrooms in which collaborative learning could take place at a distance. One feature of this special user interface was to be a Group Situation Schematic through which the essential signals that characterized the group dynamic could be exchanged.

The facilities that had been integrated into the ECOLE system were:

- Audio conferencing (limited video conferencing)
- Joint screen
- Advanced e-mail
- Electronic conferencing
- Data base search
- File transfer
- Scheduler
- Course guide
- Educational data base
  - Course catalogue
  - Schedules
  - Tutor / student listings
  - Administrative data.
- Curriculum Planning
- Questionnaire handler
- Questions & Answers
- Authoring system.

Let's put ourselves into the position of a student who enrolls in the ECOLE Campus. He might use some of the ECOLE facilities in the following order to get answers to his questions and participate in a course. The tutor might utilize the Authoring System to jointly edit, with a collegue or expert, his course CBT material based upon the feedback he or she received in the class.

Course Catalog: answers: Which course is of interest?

Course Guide: answers: What's in the course? Prerequisites?

Curriculum Planning: answers: How do the courses fit together?

Educational Data Base and **File Transer:** allows to download multimedia CBT materials.

Schedules: answers: When is the course?

Address Book: lists "office" hours & contact information on tutors.

E-mail: can be used to sign up with tutor.

Joint screen/audio-conferencing used for general co-operation and distributed classes.

Questionnaire Handler: allows the administration of tests.

Authoring System: enables the tutor to co-edit multimedia CBT materials together with an expert.

How does the ECOLE system look in the light of what we have said before? It is one of those prima fade elegant and attractive systems which generate immediate enthusiasm. However, it also one of those systems where a preconceived total educational concept was realized. The concept is a new form of learning environment which differs in too many aspects from what we are used to, i.e. from the traditional systems of learning that have evolved and stabilized over centuries. Even though we all agree, that our educational systems need overhaul, we also tend to underestimate how much optimization goes on in a long development process.

As much innovation as was attempted in one swoop in the ECOLE system is not playable with a chance of realization and survival. The major principle of socio-psychological application of informatics has been violated: Building on existing proven structures and developing new structures in short implementation - evaluation - redesign cycles.

VOICES FROM COMPUTER-SUPPORTED COOPERATIVE WORK

Part of learning technology can be seen as a branch of Computer-Supported Co-operative Work, a field which deals with computer-based tools for tele-working and other co-operative activities. These tools range from schedulers to joint editing software for distributed groups.

The CSCW community realized years ago that systems, even when they were conscientiously and capably planned to relieve acute needs, even when they were appealing and seemed helpful at first glance, in the majority of cases did not perform well in an actual user environment. The reaction at the time had been to intensify pre-design studies of the prospective user groups and to analyze their history, cultural environment, cognitive style, and group dynamics in depth.

This approach was successful to a certain degree. Especially helpful analyses resulted when ethnographers were employed to conduct such studies. After failures with straightforward approaches, awareness had grown that CSCW was dealing with a complex world of hidden phenomena, a situation ethnography has been in all along and has crafted a methodology for. Part of the ethnographical perspective is avoidance of preconceived notions and careful observation of the subjects. Such a perspective exerted a beneficial influence on CSCW where careful user observation before the design phase and user participation during the design phase were henceforth considered indispensable for the success of a project.

The approach gives an indication, though, of what kind of caution is in place if information applications are used to deal with human interaction.

Human interaction covers a broad spectrum. CSCW has been very successful in areas where the social interaction between participants is non-critical and incidental to a specific focus. An example is distributed collaborative designing and manufacturing which has revolutionized a number of industries. Today's aircraft industry, for instance, develops and manufactures components for its products world-wide. Engineering design and manufacturing are highly goal-oriented activities conducted by engineers. In this context the subtleties of interaction are less important.

In other types of human interaction where the social and *psychological aspects of interaction are critical*, it is the incidental, accidental, seemingly coincidental, certainly unpalatable, contacts that determine creativity and the richness of the outcome. This is especially true for collaborative learning such as it takes place in seminars, classrooms, or any kind of instructional sessions. Accordingly, success in this area has been elusive.

There is not sufficient knowledge on the complex group dynamics and complicated signal exchanges between participants of an educational event. Little is known as to which elements of these group dynamics are so essential that they need to be taken into account in distributed systems to make an educational event successful. There are no substantiated guidelines by which essential elements can be distinguished from nonessential ones. Such a differentiation is indispensable, though, since the real-life signal exchanges will have to be pared down to limit equipment costs and transmission bandwidth. Not everything that goes on in a classroom can be transmitted. What makes the situation even more complicated is the high degree of "situatedness" of educational settings, i.e. every setting is different.

ADVICE FROM CSCW

Over the years, the CSCW community has developed a catalogue of guidelines:

- *Study user environments carefully.*
- Investigate the social, political, and motivational factors active in the target group.

- *Be sensitive to changing needs from user group to user group.*
- Insure high context-sensitivity in the design process.

- *Involve social scientists such as anthropologists and ethnographers in the group analysis.*
- Use video-based interaction analysis as an effective research tools.

- *Support informal communication.*
- Support informal mechanisms of social control.
- Design for group control of the group's space and resources.
- Find a group-specific compromise between system passivity and intrusiveness.
- Structure group processes and provide facilitation. Assign responsibility for the facilitation function.

- *Avoid small communication barriers.*

- *Make the user interface tailorabte.*
- Keep the system flexible by building in many switches that allow a broad range of configurations.

- Plan for exception handling and low-frequency events.
- Design for open protocols allowing group ware implementers and administrators to create a wide range of interface and interaction policies accommodating group differences.
- Provide a variety of floor control policies.
- Devise a group-specific plan for managing acceptance of a system.

- *Prepare users for change.*
- Insure early and continual focus on users.
- Involve users in the design process.

- *Insure early and continual user testing.*
- Use mock-up simulations during the design process.
- Support mutual education of designers and users.

- *Mediate between the users' and the technicians view of the system, and guard against the dominance of the technicians' view.*
- Seize the "window of opportunity" for system introduction.
- Exceed the critical mass of system utilization fast.

- *Lay out an iterative design process.*

Would this set of guidelines lead to a practical procedure of designing and implementing a system? I think not. There is too much to think about, and in the end there is no guarantee that we did everything right. What this set of guidelines really indicates is the unpalatable nature of information system design for applications in the socio-psychological sphere.

We are dealing with phenomena that are so multivariate in nature that there is no hope of developing a procedure based on a set of rules for developing a system from beginning to end, i.e. realizing an innovative, pre-conceived educational concept through learning technology.

LOOKING FOR BASIC PRINCIPLES TO GUIDE US

What are we to do then? After half a century of informatics it has become clear that there is a basic principle for applying computer technology to the socio-psychological sphere if success is to be ensured:

When introducing technology, build upon existing structures, however deficient they might be, and advance in small steps to new patterns and practices.

This way, user environment studies and interaction analyses automatically merge with the development process. They are then no longer expensive separate projects. Artificial phenomena are avoided. Conjecture is reduced to a minimum.

The catalogue of guidelines from CSCW can then be used as a set of reminders and consciousness raisers while the user needs of the particular setting determine the progress of system development. It is good to keep in mind that high priority must be given to satisfying the often neglected social needs of the learner. There is a tendency to assume that the learner just wants to learn about a subject when in reality he will be comfortable with learning only if his social needs are met at the same time. It is also important to realize that social needs cover an extremely broad range. Engineers will usually put up with most anything including dismal didactics and low technical quality. They are highly trained in making sense out of seeming chaos. Children tend to be the most sensitive to social dynamics.

GUIDELINES FOR LEARNING TECHNOLOGY

Social needs can be met in two ways:

Create a careful mix of traditional learning, based on physical presence, and technology-based tools in which social interaction will be reduced;

or include in the technology, as much as possible, the opportunity for signal exchange geared to social interaction.

The latter possibility is a precarious one and is fraught with pitfalls. Here again the situation varies widely from learner environment to learner environment. Valuable contributions have come from the developments of tools for Tele-Presence. Telepresence aims at mapping our everyday signals with which we regulate our social relations onto technical metaphors which are realistic enough, so that technology recedes in the users awareness. Telepresence is the frontier of the field and must be considered experimental at this point. Here again, my advice is to start from traditional methods and advance by adding on technology.

A very important factor to consider is the phenomenon that we might call the **malleability of human behaviour.** Individuals adapt their behaviour to achieve their goals despite obstacles in a technological environment. If an unfamiliar technology promises to meet unsatisfied needs, people will make astonishing efforts to adapt. If needs are not strong or are expected to be satisfied more easily in other ways, the readiness to adapt is surprisingly low.

This means, however, that **content is of exceeding importance.** If the content is interesting to the learners in a particular environment or is acutely needed, learner acceptance of technology is surprisingly high. If the content is boring or of marginal interest, the best technology will be viewed critically or even rejected.

If starting from established structures and advancing in small steps when introducing technology is the first law of informatics for education and training, then the second law is: **Introduce learning technology only if the content to be delivered is determined, is genuinely needed by the target group, and provisions are made to ensure high quality in structure and presentation of the content.**

High quality presentation is another frontier. There is still a dearth of presentations in which the power of visual communication is fully exploited. Our sense of quality is actually distorted by the mediocrity of the visual part of most video tapes and television programs. The majority of them have moved away from the preponderance of the written or spoken word only minimally. Most visual signals are mere aesthetic embellishments of the spoken or written word. The visual part still is almost exclusively the packaging of the word using up most of the bandwidth, i.e. most of the money. In developing a visual culture in which the viewer demands that the power of visual information be used to inform and teach him or her rather than please him with aesthetic, but meaningless, embellishments, we are at the very beginning.

The kinds of obstacles people will readily overcome if the content is needed and/or interesting is not totally arbitrary. Experience has shown that **picture quality, for example, is not highly critical.** Since the transfer of visual information devours most of the bandwidth and therefore money, here is an opportunity to economize.

More critical are interruptions or waiting periods. Generally speaking, any technical performance aspect, even if flawed, that still allows the learner to be drawn into the content and/or the interaction with instructor or co-learners and allows him or her to forget the technology, is acceptable; on the other hand, **any interruption of the signal flow or a period during which the learner has to wait for some technical feature to function will break the learners attention and focuses it back on the technology, and should be avoided as much as possible.**

CONSEQUENCES FOR SYSTEM PLANNING

There are many situations in which the two laws I have presented, namely advance from existing structure in small increments and begin system development with the focus on content, are hard to comply with. Sometimes a decision on the introduction of a learning technology on a larger scale is unavoidable if, for example, a system is to be planned for a population that otherwise is not reachable at all because it might be widely dispersed or if the number of instructors is too small for a given population. Sometimes funds need to be allocated if their loss is be avoided. The allocation of funds, of course, presupposes specific and detailed plans. Funding agencies will rarely content themselves with plans for extended experimentation.

In such a case the only solution is to rely on systems that have already been successful. What would be a measure of success? Systems should be considered successful if

(1) they have been used in actual user environments and have taken over the function of traditional structures and patterns of learning and teaching to the extend that they have proven their viability in preparing learners for professions and taking learners to certification and degrees, and if

(2) they meet a high degree of acceptance in the user community.

The only learning technology that meets this criterion and can look back on decades of experience is Interactive Television for Education and Training. I am using the long name because the term Interactive Television alone, in some parts of the word, e.g. Europe, is often associated with entertainment and tele-shopping. In Europe the term Tele-Teaching is more and more used for ITV for Education.

EXPERIENCES IN ACTUAL LEARNER ENVIRONMENTS: *INTERACTIVE TELEVISION*

Interactive Television has been used extensively in many US-American universities. A wealth of experience with this technology is already available. Equipment, classroom design, didactic parameters, conduct of lessons, and administrative structures have already been considerably refined and well integrated. The performance of this technology can be gauged by the strong demand for it, the increasing number of diplomas earned through it, and its economic success.

Most of the experience with Interactive Television has been gained from settings in which a video signal is broadcast or directly transmitted to receiving sites that are in two-way audio contact with the originating site (one-way video / two-way audio). This is a very effective and surprisingly low-cost form of Interactive Television. For some purposes Interactive Television should be expanded to two-way video / two-way audio. Good results have also been achieved with learners viewing taped instruction under the guidance of a tutor (as in Stanford University's Tutored Videotape Instruction).

Building on extended experience with these basic forms of Interactive Television, US universities are now moving to combine them with other technologies (e.g. computer video). Integrating various forms of telematic tools (e.g. email, computer conferencing) will give Interactive Television added effectiveness.

In the United States, to a limited degree in Europe, educational institutions can look back on many years of methodological, economic, and pedagogical experience of actual ITV course delivery for credit. Consequently, in ITV we **have a technology in which cost-benefit ratios and pedagogical efficiency have already been optimized to an appreciable degree and which can serve as a reliable platform for further development of telematics for education and training.**

While a multitude of PC-based learning environments has been developed, none has been employed in actual user environments to a remotely comparable degree. However, we can see television and computer technology growing together and institutions employing ITV moving toward computer-enhanced systems that can bring instruction to individual learners at affordable cost without the necessity to use expensive learner sites.

An argument that is often advanced against Interactive Television concerns high production costs. Production costs will be high if developers let themselves be lured into satisfying the viewing habits that have been trained by commercial television. **Costs can be dramatically low if ITV operators stay away from the style and practices of commercial television by deciding not to compete with any aspect of commercial** TV. American universities have shown that users can be led to develop different viewing tastes and habits that are more related to content than the over-stimulating, content-void flicker of commercial TV.

INTERACTIVE TELEVISION: A SUCCESS STORY

Interactive Television has gone through the type of development which I advocate for all learning technology. Initially, some lectures or classroom instruction periods in the traditional format were broadcast to distant locations or were taped for later viewing. Once this was accepted as a welcomed increase of flexibility, the desire for interaction arose. Interaction could be added easily by using the telephone as an affordable feedback channel. The waiting periods caused by dialling the number and waiting for the connection to be made was a considerable obstacle in the light of what I said before. Ways were sought by which an audio connection could be made instantly. This could be done in a variety of ways: the line could be kept open, which increased costs; a line could be leased where traffic warranted it: ISDN's fast switching capability could be used where available.

Over time, a variety of modifications evolved. Where the nature of the educational event was basically asymmetrical, even with intensive interaction, one-way TV / two-way audio proved to be sufficient. Many US educators even argue that they prefer one-way TV for instructional purposes because it provides for better focus than two-way TV. Where educational events are symmetrical as in the case of two groups collaborating at a distance in a seminar-type setting, two-way TV is, of course, to be preferred. However, two-way television is very expensive because of two-way point-to-point or point-to-multi-point transmission. This is the area where the growing together of computer and TV technology with the help of bandwidth-scaleable switching technology, e.g. ISDN (to a very limited degree) and ATM, will be pushed by demand.

US universities are now at the point where they are ready to introduce computer networks and computer-based tools on a broad scale to enhance ITV learning technology on the basis of their solid experience with this medium.

WHAT'S REQUIRED FROM A SYSTEM FOR OPEN AND FLEXIBLE LEARNING

In the light of our discussion, let us ask how a learning technology for Open and Flexible Learning would have to look that satisfies the following conditions:

The Learning technology

- can be built upon existing structures and patterns of learning,
- makes use of technology that has been proven in actual learner environments,
- permits incremental development while allowing planning into the future for funding reasons,
- provides for the opportunity of a good mix of modes and media for learning in response to the needs of the particular situation,
- is built using existing equipment reducing development and equipment costs,
- has a good chance for international standardization of components alleviating compatibility problems in cross-border learning,
- holds out the prospect of international cooperation of equipment and service providers,
- is modular to allow further development through the exchange of modules, and
- has the potential of growing into an international Education Highway.

Such a system is already in the making and a description of it will not seem spectacular or even innovative. However, it is important that we reinforce evolution and avoid revolution in learning technology for the reasons we have discussed. If we exert an influence on the evolution that is already under way, we have the best chance of succeeding in meeting the goats we have in providing good learning opportunities world-wide.

CONTOURS OF AN EMERGING EDUCATION HIGHWAY

I think the above-listed stipulations are best met by a system which is based on interactive television and is made up of components that can exist independently, but fit together as modules in different configurations. Tools based on computer and network technology will fare best if they are used as components in such a system.

The components of this system are:

Broadcast Television (terrestrial, cable or satellite).

- Television as an educational tool can be used either stand-alone or as the video part of interactive television.
- Television has spread around the globe and is available in the most remote regions.
- Through mass production and television's ubiquitous presence costs are low.
- There is already a culture of offering and taking instruction by television in many countries.
- In the wake of television, video recorders have almost equally proliferated around the world. Therefore, instruction by television and by videotape are compatible technologies which can be used in a number of different configurations: Videotapes can be sent to learners; learners can tape lessons from television broadcasts; in Tutored Videotape Instruction scarce high-quality material can be combined with the advantage of interaction.
- Education channels already exist in many places. Patterns of supporting educational television are established political structures in a great number of countries.
- More and more instruction is offered on video tape.
- A task that lies ahead is setting up alliances between television channel operators, content providers and operators of feedback channels (telecoms) to use broadcast television as interactive television where needed.

Classroom Television

- With broadcast television normally too expensive for delivering education to small groups, there have to be facilities that allow television transmission of educational events at minimal costs.
- Over many years of delivering university education by interactive television, US universities have reduced costs dramatically through equipment selection, classroom design and production practices. **Production costs for an educational event are in the range of 100 to 200 US dollars per hour.** That is a totally different dimension when compared with normal television production costs.
- Every opportunity to cut costs has been taken advantage of in these classroom productions. To quote just one cost factor, classrooms appear to be no different from ordinary classrooms and seat the normal amount of students. The technology is unobtrusive, and the instructor or professor holds a lesson in his or her accustomed way making use of the props he or she is used to (blackboard, overhead projector, video demonstrations, computer read-outs etc.). This arrangement means that the instructor needs no television training, and no rehearsal is necessary. In these settings, at the most one operator is necessary who is present only during transmission time and replaces a whole television production crew.
- Classroom television can be transmitted via local links or fed into broadcast networks. It can use feedback channels from the telecoms.

Feedback channel network

- All prerequisites for a differentiated network for feedback channels for interactive television are in place. The still missing link in many places is cooperation between the telecoms and television operators in tailoring feedback services to different types of ITV events and having them available when ordered.
- The service will depend on the nature of the educational event, cost considerations and the availability of technology in a specific area.

- POT, Plain Old Telephone, is available in most places. In the case of older switching technology, either the disadvantage of waiting times for establishing connections would have to be tolerated or lines would have to be kept open for the duration of the event. If institutional support is available the cost for the individual learner or learner group could be reduced by establishing a network of local telephone numbers for the specific purpose of a long-distance feedback network.
- An attractive spectrum of services can be offered where ISDN is available. Connecting times are minimal. A person can be acoustically connected to the instructor practically without delay by pushing his microphone button.
- ISDN, though, offers a lot more. Feedback channels can transmit video without prohibitive costs. This way, two-way video is realized at very reasonable expense. For many applications a transmission rate of 128 Kb/s is quite sufficient the cost of which corresponds roughly to two simultaneous telephone calls.
- A transmission rate of 386 Kb/s will tie up 6 ISDN channels and produces a picture that for most educational applications can be termed high-quality. The transmission cost is still reasonable for many situations where groups of learners are served at the receiving end.
- Depending on the nature of the educational event, an ISDN feedback channel network can be used as a stand-alone facility for seminar-type events. For those applications the telecoms must have the required bridge technology available, so that ISDN conferences can be set up.

Computer network support

- In the environment I am describing here, the various facilities of the "comprehensive learner environments", such as email, file transfer, computer conferencing, data bank and Internet access have the best chance for successful development into viable services. In this environment they can be gradually added on and tested for efficiency and user acceptance.
- These kinds of services can, of course, also be added on to traditional educational structures and practices and provide great benefit. My argument had been that it is risky to introduce an educational system based exclusively on such facilities in one step replacing previous and proven structures. By expanding a platform the success of which can be ensured with greater certainty, the facilities of the "comprehensive learner environments" are placed in an environment in which they have a realistic chance for successful development.

On purpose I am suggesting a system, or better environment, that is based on existing technology. My focus has been on patterns, structures, and practices of learning, as well as political and private sector cooperation, rather than specific technology.

The most important question is: How can we influence patterns and structures, so that technology will be benefit the learning process and is accepted. In the educational environment that we are creating that way, it is relatively easy to exchange technical components.

In today's fast paced technological development we cannot afford to wait for the next generation of technology to arrive. By that time a new development will be on the horizon. Also, it always is hard to predict when a technology that might already exist is ready to be introduced on a large scale.

The technological changes that are probably not too far off in the future are the growing together of television and computer technology and extension of the switched networks to scaleable high-bandwidth transmissions If the basic patterns of technology-supported open and flexible distance learning are laid out as described, it will not be too difficult, in any case manageable, to exchange technical components.

The original is presented in English

Discussion

THE IMPORTANCE OF MULTIMEDIA FOR VOCATIONAL TRAINING

Gerhard Eisfeld

FEDERAL MINISTRY OF EDUCATION,
SCIENCE AND TECHNOLOGY, BONN (GERMANY)

1. VOCATIONAL TRAINING AND CONTINUOUS EDUCATION SHOULD DEVELOP INDEPENDENCE AND INITIATIVE

Let me tell you about an interesting episode. Two years ago a Russian of the German descent came to Germany and settled in Bonn. His ancestors came to the Lower Volga on the invitation of Catherine the Great 230 years ago. She offered them very good conditions for settlement so the chap found a job as a metal worker and he is still working there.

Once the machine tool stopped: something went wrong with a bolt. There was not a spare bolt in the workshop and there was nobody to ask for it (the master was away) so he sat down in the corner, opened a box with his food, picked up a newspaper and waited. In three hours' time the master and a foreman came and wondered why he was not working though the work had to be done in the morning. The young man explained that he could not work on the machine tool because it broke down. Then the foreman asked him why he did not go to the hardware store to buy the bolt to be able to go on with his work. The chap answered that it had never occurred to him. Why had it never occurred to him? Because in Russia where he came from the state took care of everything, it was not his job to solve such problems.

Gorbachev writes the following in his memoirs, «Under Stalin's system the initiative was forbidden»! This is a very good illustration of the main difference between economic and educational systems in Western and socialist countries.

Our economic system which to be more advantageous can only operate if people can work independently, are full of initiative and if they are cooperative. To behave like that they should learn it while in the kindergarten, in general school, in vocational school, then to learn such things at university and after that the whole life in the system of continuous education. The state and society should grant them sufficient freedom, so that they could act independently and take part in decision making.

A week ago the chief of a kindergarten and a school director came from Moscow to Bonn to get acquainted with our kindergartens and schools. When visiting a kindergarten they were quite surprised to see how the so-called «free games» were organized. Every child can do what he/she wants: to construct from toy blocks, to play with dolls, to do gymnastics or draw. In the view of our guests it was a complete chaos, no discipline at all because the teachers almost did not interfere with what the children were doing. Our guests criticized this method of education And we, their friends, tried to persuade them that it was done on purpose: the method aims at developing independence and initiative in children.

I have chosen this two examples to show the essence of our philosophy of education.

The educational objective besides independence and initiative includes the following two points.

II. HIGH QUALIFICATION AND APPROPRIATE DIPLOMA FOR EVERYBODY

1. The objective must be set: to ensure everybody (as far as possible) the opportunity to get high qualification at general and vocational school!

We believe it necessary that everybody should get the specialty he/she is cut out for, that is at first a basic professional training in the chosen field, then professional improvement, after that life-long learning in the system of continuous education. Qualification standards in vocational training and education are set by the state.

2. Equal opportunities for all:

Every child, every pupil, every young man or girl, every adult should have an opportunity to improve their qualification any time. In other words we have created the system of differentiated education which takes into account individual abilities and talents. Within the frames of this system everyone can change specialization and/or to continue training at a higher level. Our system of education is flexible and open. We hope to ensure through it equal opportunities for all. It comprises social maintenance for young people and adults with scanty means and also for people with deficiencies.

III. EVERYONE HAS THE RIGHT TO TAKE PART IN THE ADMINISTRATION OF EDUCATION SYSTEM

There are administrative boards in kindergartens which are chosen by parents and which help teachers. In schools schoolchildren are represented by the school parliament (consisting of schoolchildren) and the special representative from schoolchildren, as for parents they elect the representative board from parents. Self-government in vocational schools and in higher educational institutions is organized in the same way where students elect their representatives. There are boards of representatives at enterprises and in offices which participate in decision making relating to continuous professional training, in-service training and continuous education.

Parents also take part in decision making about a further form of education for their children, that is what secondary school he will be enrolled in after 4 years in primary school: general school (5-6 more years), general college (6 years), lycée (9 years) or polyvalent school.

As for the organizational structure schools are similar in all 16 lands of Federal Republic of Germany but they differ in educational contents, for example in the subjects taught and the methods used, in organizational work and interior regulations.

In the federal system of FRG school education is in the competence of the lands. The Federal government in Bonn is responsible for professional training at the place of work as well as the use of the Frame Law in higher education.

IV. THE SYSTEM OF EDUCATION IS BEING CONSTANTLY IMPROVED DUE TO THE REALIZATION OF RESEARCH AND PILOT PROJECTS

We are constantly improving our system of education, for example using multimedia in schools, in vocational training, in higher education and even in kindergartens. We are never satisfied with the progress we are making in the system of education! The latter being constantly improved on and it can never regarded completed.

V. THE IMPORTANT ROLE OF MULTIMEDIA IN VOCATIONAL TRAINING

1. Multimedia and competitiveness

Those countries which have small reserves of natural resources or none at all can occupy a proper position on the world market only due to inventions, intellectual achievements and products which can be sold.

The Federal Republic of Germany is one of them.

It is necessary that such countries should have a highly developed system of vocational training and continuous professional education. Nowadays it is only possible through the introduction of multimedia in education. High quality vocational training is a necessary conditions of the countries' economic advance and therefore of the welfare of its people.

The fact that the special knowledge on informatics should be renewed annually on technology - every 3 years, specialized vocational knowledge - every 5 years, knowledge acquired in university - every 10 years, at school - every 20 years is indicative of the necessity to use multimedia thanks to which one can quickly attain the proper level of qualification with due regard for modern requirements. Life-long education is taken for granted this days and multimedia make this process easier and become its decisive factor.

Both basic and continuous professional education can be considerably improved by using multimedia both in qualitative and quantitative aspects.

That is why should be actively integrated into educational process as soon as possible in secondary schools and in higher education institutions, in the system of inside-the-firm training and at the centers of vocational training. This process have already began first of all in higher education institutions. The integration of multimedia in education is a great interest and it considerably increases students' motivation. We know from experience that children and young people whose work on the computer is in the form of a game enjoy it immensely, and thus they have motivation.

Multimedia is a combined integrative use of various types of media in interactive mode (or with the opportunity to work in this mode) based on the application of digital technology. Multimedia broaden the traditional resources of communication, they accelerate the access to various data. One can select top quality information from a large array. It is accessible at any time irrespective of where you are at the moment. Neither work nor education depend on where the place of work or educational center is located. One can give the following reasons from the sphere of psychology in favor of the necessity to integrate multimedia:

- Multimedia activate all human senses.
- Motivation increases if forms and conditions of work change.
- The process of learning is activated due to interactivity.

This completely changes former organizational methods of basic and continuous professional education and conditions of work: the organization of these kinds of activities in time and space. It becomes possible to receive and to use the necessary information of the required quantity and quality when and where one needs it.

It means that:

An enterprise which has a large database can make this knowledge available through multimedia for all the stuff of the firm, it will enable everyone on the staff to get access to all technical data of the enterprise. It will sharply increase the potentialities of basic and continuous professional education and also the possibilities to create new kinds of production.

The first surveys concerning the use of multimedia technologies in basic an continuous professional education showed that these technologies have the following qualitative and quantitative advantages:

- reduction of costs due to the decentralization of places of education;
- reduction of the periods of education;
- reduction of expenses on the development and the extension of the courses;
- individualization of teaching: transfer of knowledge etc.;
- training at the place of work or nearby.

2. The realization of pilot projects of the Ministry of Education, Science and Technology in the area of multimedia - two examples:

2.1. The project «Integration of schools into computer networks» is the starting signal for the future development of the system of education in the Federal Republic of Germany

In 1995 not more than 2 % of population of the Federal Republic of Germany over 14 years old looked in the Internet from time to time, now the situation is different: because now about 50 % of secondary schools are using multimedia there will be the a sharp increase in the use of computer networks in the educational system within the next 3-5 years. Having trained all the students in managing multimedia we will be able to improve the quality of their training, and in the end these new opportunities will be used by the majority.

The Federal Ministry of Education, Science and Technology of the FRG in association with Deutsche Telecom and the administrations of the lands has made a decision to integrate about 10,000 schools into computer networks within the next 3-5 years. Implementing this project its sponsors expect the institutions of local government (communes) financing schools and also the parliaments of the lands responsible for local school education to contribute on a larger scale to the informatization and integration of schools into computer networks. We also expect that the number of enterprises willing to support this project financially and by giving the equipment will grow. The national company Deutsche Telecom has already allocated 36 million marks for the purpose. The Federal Government on its part has allocated 23 millions marks. German manufactures are also rendering a considerable financial support.

All state schools providing general education and vocational schools, all the lands and the teacher-training colleges financed from their budgets, all centers of vocational training and continuous education, continuous professional training of teachers inclusive, can put in applications to be integrated into computer networks. The cooperation with the outside partners (communes, enterprises providing multimedia, research institutes) is encouraged in every way.

This policy in the field of education and the given project includes the development of skills by students and other sections of population when working with the interactive technologies which are already integrated in other spheres (the organization of leisure and professional spheres), the development of international cooperation among students, teachers, schools, creative work on new educational programs, learning and self-education using multimedia technologies, the use of databases and libraries, the exchange of methods of education and didactic materials, mainly to reduce the teachers burden.

The project «Aqua Data» can serve as a good example of using the potentialities of telematics for technical education and other educational courses, it is connected with the teaching of biology, its purpose is to analyze the quality of water at practical lessons on protection of the environment.

The project makes it possible to analyze the quality of water. Students and teachers take samples and put the data in the computer linked to the central educational server, from which one can get the program of the analysis.

This educational server becomes *vade mecum* (Latin: guide) through the German educational computer network which is developing rapidly. It is also linked to regional (land) educational centers.

The central server sends educational materials to the Internet in a prepared and «readable» form, ensures their search with electronic references (the so-called *links).*

«Technology must serve pedagogics» - this is the main principle of the federal initiative «Integration of schools into computer networks». The main thing here is not the demonstration of technical potentialities but a didactic expediency: to arm teachers and students with the method of receiving and processing of information. In every single case the decision about financial help is made depending on the pedagogical quality of the project.

To make it possible for schools to participate of the realization of the projects connected with multimedia, they are allocated financial and technical resources (within the framework of the federal project mention above) to buy and to maintain the equipment. The following expenses are paid off:

- providing with special computers for network interaction,
- setting up a local school network for the interaction of the school computers,
- linking to the global network,
- network maintenance expenses including telephone charges,
- pay for databank use,
- training in using the whole technical infrastructure,
- aquisition of technical software.

2.2. Continuous professional education. The interactive program of computer (through CD-ROM) teaching of teachers at inside-the-firm sentence «Pedagogical Knowledge and Methods of Work».

In the Federal Republic of Germany there exists the so-called double system of professional education: theory is taught to pupils at schools (vocational schools) and practical skills are taught by teachers of inside-the-firm educational centers (at enterprises).

At present in Germany 5.3 mln. people are teaching in the system of inside-the-firm education (training at the enterprise), for 572.000 people teaching is their main job, and continuous professional education is a must for them. For the other teachers working in this system (about 4.7 mln.) teaching is by-work; 68 per cent of them are willing to be taught in the system of continuous teachers' education.

Teachers of vocational schools get basic pedagogical knowledges in colleges of education. However teachers at enterprises are selected from highly skilled and very efficient practical workers but having no pedagogical qualifications. They are included in the teachers' continuous education in Chambers of Commerce or attend some similar educational centers. The course lasts at the minimum for 120 hours and the purpose is to arm them with pedagogical knowledges and methods. This activity is regulated with a special decree of the Federal Government adopted within the framework of the Law about professional education.

The main task of this educational system is to provide highly skilled training of teachers conducting vocational training, so that they could pass good skills to their students. The better the working force is taught the higher is the quality of production both industrial and handicraft. At present the system of professional education is being equipped with the latest multimedia means in basic and continuous inside-the-firm professional education aimed at further improvement of teachers' education.

The special study «Advantages and risks of using multimedia interactive systems in the basic and continuous inside-the-firm professional education» carried out the Federal Ministry of Education, Science and Technology of the FRG in 1994 showed that the use of the computer enables to transfer information in a more flexible and efficient way. The computer may become an extremely important tool of basic and continuous professional education at the enterprise. However this report mentions that the didactic level of the working-outs is not sufficient yet. First of all the didactic preparation of materials should be improved on. There are virgin lands to be cultivated by teachers, designers of multimedia means, video- and audio-operators. At the present moment some exemplary multimedia programs should be developed for a limited number of groups of users to see which didactic means stimulate and motivate their active use.

The program «Practical training at enterprises: interactive program for teachers' education» has become the fist step in this direction. This program was financed by the Federal Ministry of Science and Technology of the FRG, and it was developed and tested by a «Siemens» Company in Munich. It is mainly for the teaching staff in the system of professional education who teach young people to operate machine-tools and other tools in working shop. In the FRG we call these staff «foremen teachers». They work at business and they know all the requirements of production. They are responsible not only for the teaching of new skills to their trainees which are indispensable for this particular job but also general technical knowledge and skills. The program under consideration can be used not only to train foremen teachers but to train teachers for vocational schools who study at universities and later will cooperate with foremen teachers in business.

The interactive program under consideration based on the application on several multimedia means comprises three parts (blocks):

a. the multimedia educational program for interactive automatized training (computer-based training) on the use of multimedia in education and the introduction to the problems of continuous professional education;
b. the program of professional teachers training in the given specialty intended for foremen teachers which materials can be presented on a paper carrier, and at last
c. instructions for teachers on the use of the program.

All the three parts are recorded on a CD-ROM. The expenses on its development were paid off by the Federal Ministry of Education, Science and Technology of the FRG and a «Siemens» Company.

The combine use by the teaching staff of the blocks (a) and a program (b) (we mean the introduction in the problems of industrial training and the training in use of multimedia as well as the program of professional teachers' training) makes it possible for foremen teachers to be and those who are professionally improving to have individual instructions depending on the particular problems which have to be solved. They choose the time and the duration of learning sessions themselves with regard to their demands and the situation at work. This method to «quantumise» learning sessions as the problems arise enables to connect them with particular situation; this connection is also provided through the set of videoclips introduced into the program and in which particular situations at business are shown, the foreman teacher can watch them and then show them to his trainees.

The block (a) has a module structure and comprises eight modules:

• The first module contains instructions explaining how to work on the computer and the principles how to organize continuous professional training.

• The second module gives the description of the advantages of cooperative training of students and the cooperation of teaching staff.

• The third module shows how to work out the outline of industrial training at a business.

• The fourth module gives the description of the main opportunities: how to acquire and improve ones qualification.

• The fifth module gives explanation to foremen teachers how to analyze the situation at work, to presented in the form of educational material, educational situations. It enables foremen teachers to single out jobs trainees can be instructed to do as industrial training.

• The sixth module shows to the foreman how to describe to the trainee the area of his future activity (the organization of introductory talk).

• The seventh module answers the question «How to choose the best method oftraining?».

• The last module «The Manual for Foremen Teachers» summarizes the program of continuous professional training and shows the prospects of further professional development for teachers: the working-out by the foreman teacher himself of his own methods of training.

Thus 8-module block (a) ensures that foremen teachers to be master basic pedagogical knowledge, necessary to prepare them for work.

Videoclips make it possible for foremen teachers to realize better what are the problems to be training of young people and how to solve them. Educational situations are rendered concrete by such means as cartoons, schemes, video and audio information. The films comprise questions and answers stimulating creative thinking over the situations by foremen teachers.

Block (b), the program of professional teacher training - comprises special exercises intended for foreman teachers who are to apply the acquired knowledge into a particular educational situation: the coordination of the working plan of a business or subdivision and the plan of industrial training; compiling of a question list for the first talk with the students. At the same time this manual is the foremen teachers' reference book which he can supplement with his own notes and thoughts.

Block (c) - instructions on the program's use for the teaching staff - enables to maximize the efficiency of foremen teachers' training. We have the post of the instructor on foremen teachers' training. These instructors' duty is to help foremen teachers, they also use in their work the materials of the block, that is the interactive program. Experts who have a great pedagogical and methodological experience in the sphere of industrial training work as instructors. They can answer questions from foremen teachers arising in the process of work or self-training. Instructors can help giving advice on how to organize training in small groups, how to work-out a time-table for it. They should carry on in-depth tasks and discussions with foremen teachers on all these issues. Their main task is to show to foremen teachers how to organize self-training of young people, including the use of multimedia.

This multimedia program of training of the teaching staff in business to be able to teach trainees on machine tools to work at the working shop arises great interest abroad. It can be used to train foremen teachers in any system of industrial training of a similar kind irrespective of the specific character of work. I always recommend that our visitors from abroad should get aquatinted with it to understand how our «two-storey» system of professional training is organized and how it works. By the way you can get a CD-ROM with this program free of charge at the Department of Public Relations of the Federal Ministry of Education, Science and Technology (FRG), whose address and fax number in Bonn I can give you now: Heinemannstrasse 2, 53175 Bonn; 0228/57 - 3917.

To use this block (a) of the multimedia program you need at the minimum AT compatible with PC 488-66 MHz with MS-DOS 6.0 and Windows 3.0 established, with a hard disk not less than 120 MB, a memory not less than 8 MB, two-speed CD-ROM drive, SVGA card for 256 colors, SoundBlaster audiocard with active speakers.

3. You can apply for the videocatalogue on professional training at the Federal Institute of Professional Training (address of the Institute: Bundesinstitut fur Berufsbildung, Fehlirbelliner Platz, 3, Berlin).

In the catalogue is the great number of video courses worked-out (and tested in practice) for the needs of basic and continuous professional training; there are, as a rule, supplemented with printed materials; they are made to train specialists in the following brunches of industry, science and management: building technologies, chemistry, physics and biology, electrical engineering, woodworking, road building, metal working, economics and management; they are for teachers and intended for training in business. The above mentioned catalogue of the Federal Institute of Professional Training contains the review of all this materials and all videocourses provided with annotations.

4. New professions come into being as a result of multimedia use.

Two new professions have come into being in the Federal Republic of Germany which are now officially registered, they are the audio- and videooperator and the film and video producer. Officially authorized training in them has been conducted since 1 August 1996 (it is listed in the state register). This professions have specializations in the development of multimedia means. In this connection the possibility of the introduction of new specialties in such areas as, for instance, information and telecommunication technologies is being discussed.

5. The Federal Government supports multimedia programs in professional training and general education stipulated by the documents of the European Union.

The Federal Government renders help to the Council of the European Union in the development and maintenance of the educational computer programs in professional and general education.

The Federal Government mentions with satisfaction that the cooperation has been established between teachers and producers of multimedia programs, it also approves of the decision to pay greater attention to what users (teachers) say at the development and adjustment stages. Research projects in the field should take into consideration the efficiency and quality of multimedia programs and their impact on teaching and learning.

It is expected that the multimedia programs which have already receive financial support will be examined first to define more clearly the policy of support and privileges.

The top quality programs which have received international approval will probably be translated into several European languages with financial support of the European Union, so that all member-countries of the European Union could make use of them.

The extension and modernization of the research computer network of the FRG, the plan to reequip it and to turn it into a high-speed network, joint (national and European Union) financing of computer networks inside universities - all these examples show how the requirements and recommendations of the Council of European Union concerning the informatization of education are implemented.

Commission II

TELECOMMUNICATION TECHNOLOGIES IN EDUCATION AND SCIENCE - THE PRESENT STATE AND DEVELOPMENT OUTLOOK

I. A. Mizin

DIRECTOR, INSTITUTE OF THE PROBLEMS OF INFORMATICS,
RUSSIAN ACADEMY OF SCIENCES

INTRODUCTION

The spread of informatics in education, which is the subject of this Congress, cannot be viewed in isolation from the general development of information technologies. It is safe to state therefore that all developing and newly emerging information technologies are one way or another applied in education, this broad sphere of human activity so readily absorbing innovations.

I would like to review but briefly the history, the present state and the nearest prospect of the major component of modem information technologies, namely, telecommunications and network information computer technologies. I should like to present here a general picture to show what new possibilities can be provided by the development of some or other components of telecommunication network technologies. Technologies in this case mean the totality of computer hardware and software and the methods of their application for infonnation communication and control of big volumes of diverse data, including audio and video infonnation.

I think that one of the main objectives of this Congress precisely is to introduce to application experts new possibilities of basic technologies to be used for finding the best ways of applying these technologies in their Field, in this case in education.

1. THE PRESENT STATE AND DEVELOPMENT PROSPECT OF TELECOMMUNICATION TECHNOLOGIES

The approaching 21st century may safely be called an "information society" era. It is obvious that various states and public organisations are increasingly interested in the success of telecommunication technologies as a basis for establishing shared information space, or information infrastructure, of the globe. At present an information infrastructure is viewed as a major component of any kind of activity, as a totality of information resources and the hardware and software facilities of information technologies and telecommunication networks.

I would mention here the main factors having a political effect on the establishment of an information society:

• discussion of projects of establishing a global international information infrastructure at European Community commissions and Q-7 summits;

• EITO — European Information Technology Observatory — a large-scale European initiative designed to develop a comprehensive view on the European market of information technologies and services for a given industry for both individual users and public organisations;

• RACE — R&D in Advanced Communications Technologies in Europe — the all-European research program of developing advanced communication technologies;

• a program of establishing a U. S. National Infrastructure Plan (1993) and the 1996 U. S. Law on Telecommunications;

• a program for the development of the means of communication and informatics of Russia's Ministry of Communications, the Rostelecom projects (Central and Southern), the Interagency program of the Russian Academy of Sciences, the Ministry of Science, the State Committee for Higher Education, and the project of establishing a national network of computer telecommunications for science and higher schools. Telecommunication technologies play a key role in this sphere, determining the rate and "quality" of building an sphere, determining the rate and "quality" of building an information society.

Telecommunication technologies for building information transmission networks emerged as an individual notion only in the middle of the 20th century, and already at the end of this century we see them penetrating every sphere of human activity. There are several factors that have had a decisive effect on the development of telecommunication technologies. The first of them is progress in the microelectronics industry and the development of computer technology and the success scored of late in the technology of optical (fibre) systems.

Information transmission networks have made an immense breakthrough from telephone and telegraph networks in the first 30 years of the 20th century to integral digital networks transmitting all kinds of information (speech, data, video).

Telecommunication technologies have been progressing in parallel and were interconnected with the development of communication channels from analogue to high-speed digital optical-fibre communication lines and the total computerization of society.

The stages in the development of telecommunication technologies:

- telegraph and telephone (pre-computer epoch);
- data-transmission between individual computers along selected channels with the use of modems;
- data-transmission networks with packet switching — datagram or those using virtual links of the X.25 type;
- local computer networks (LCN) or local area networks (LAN), the most widespread of them being Token Ring and Ethernet;
- integral servicing digital nets (ISDN), broadband and later narrowband;
- high-speed parallel networks — Frame, Relay, SMDS, and ATM;
- high-speed local area networks — Fast Ethernet, FDDI, and FDDI II (the development of FDDI for simultaneous transmission of speech and video information);
- *information superhighways* (routes).

Most impressive breakthroughs in telecommunication technologies have been observed over the past 15 years.

The most significant achievements, in our view, are:

X.25. For quite long the most widespread approach to setting up data exchange networks was the one based on the ideology of space and time packet switching determined in keeping with MKKTT X.25 recommendations. Typical for this technology is packet transmission along temporarily arranged virtual channels and also fairly complex functions of controlling transmission processes to be done by a network to increase the reliability of information delivery to the user. This technology has been studied and improved many times, but it remains to be a basis for a broad class of telecommunication networks to this day. One of the reasons why such networks remain of significant practical use is their satisfactory functioning in the conditions when low and middle quality channels are used.

TCP/IP. Data-transmission in accordance with TCP/IP protocols is based on the datagram method of packet switching with independent packet routing. A number of special networks (a network of the U. S. Defense Department — ARPANET) were established with the help of this technology, which remains efficient and competes well with the virtual call method. A wide use of the TCP/IP in Internet is a good proof of this.

ISDN. To broaden the spectrum of services provided by a network, to improve their quality and to perfect the transmission of digital information, many countries began actively to develop in the mid-1980s integral servicing digital networks (ISDNs), first narrowband (N-ISDN) and later broadband (B-ISDN) ones. The main purpose of ISDNs is to transmit various types of information at a high speed, including transmission of speech, teletext, videotext, and electronic mail; and for B-ISDNs it is teleconference, transmission of TV images and parallel processing of information.

One of the main problems related to B-ISDNs was that of choosing a commutation method to be placed at the basis of such systems — commutation of channels (similar to the traditional commutation system used in an ordinary telephone network, in which a physical channel is established between a corresponding couple of subscribers for each link) or a variety of packet switching (in which a network transmits information organized in a special way into packets of data provided with an address of their destination).

The method of packet switching (commutation) is more flexible from the point of view of transmission speed and is more suitable for transmitting various types of traffic.

ATM. National and international organizations on standards have shown notable progress in the past few years in formulating the principles of a technology for transmitting diverse information. These organisations recommend for this a standardized technology of transfer, multipexing and commutation called Asynchronous Transfer Mode — ATM.

ATM is a variety of the packet switching method with virtual channels and it combines to a certain extent the advantages of channel switching and packet switching methods.

The basis for the ATM is a single digital format and common regulations of the transportation and commutation of all kinds of information, including service information.

SMDS. Switched Multimegabit Data Service is a high-speed commutation service of data-transmission, similar in its properties to the ATM, but, as distinct from the latter, it uses the datagram commutation method.

The current specification of the SMDS offers users access on a selected line with a speed of DS1 (1,544 Mbps) and DS3 (45 Mbps).

Frame Relay. The Frame Relay (FR) technology is a variant of the packet switching method. It emerged and developed as a technology designed precisely for transmitting data, but at present it is increasingly used for the exchange of speech and even video information.

A distinctive feature of the FR technology is partially refraining from complex procedures of spotting and correcting mistakes during the transmission of information along communication channels. This allows to make the most of the channels' capacity and of the resources of the commutation equipment.

The FR technology is an effective means of linking local networks. At the same time, the use of powerful mechanisms of multiplexing and controlling the flows used in the FR method makes it highly capable for integration and for increasing the efficiency of global and national networks, especially when there is a great variety of protocols, in accordance with which users transmit their information to a network.

10 BASE-T. Though the Ethernet technology appeared over a decade ago, it is the 10 Base-T standard, devised by the IEEE 802.3 committee, that led to its wide application in the late 1980s. The standard which determined the Ethernet development with the use of non-shielded twisted-pair lines changed the nature of the LANs.

The 10 Base-T standard specified the use of the topology of the "star" type and concentrators, which made networks more reliable and easy to control.

As soon as the industry recognized 10 Base-T as the main method of building Ethernet, the price of concentrators and network interface cards dropped a great deal, which encouraged the wider spread of this technology.

LAN Commutation. The appearance of commutation marked immense progress in LAN technology. As distinct from the technologies of parallel LANs, where a fixed capacity is divided among the devices connected to a LAN, commutators made it possible to give each port a capacity of 10 Mbps, greatly increasing the capacity of LANs and improving their characteristics.

The ATM technology has stimulated still more the development of LAN commutation. The ATM differs from other technologies in that it supports the transmission of speech, data and video information at the speed of hundreds of megabits per second. Possibly, the ATM will become the first technology used in local area and territorial networks.

Distributed Optical Fibre Networks. The use of optical fibre in distributed networks allows to guarantee practically unlimited speed of information transmission, its high quality and reliability. Companies owning remote communication networks use the technology of digital communication with optical fibre to rearrange their networks entirely. And so do Russian telecommunication companies.

The wide use of optical fibre has required new technologies of digital transmission of signals. The technology of synchronous digital hierarchy — SDH/SONET — proved the best. It gives standards for data-transmission at the speed of up to 2.4 Gbps with a possible increase up to 10 Gbps.

Wireless Networks of Mobile Subscribers. The achievements in the past decade in mobile and wireless communication systems (especially satellite and cellular ones) give users access to networks capable of transmitting data from any place, also during movement.

The most widespread technologies at present are those using the MPT, NMT-450, AMPS, and GSM standards.

These technologies are being developed and are improved. One of the more promising directions here is the use of the CDMA method — code division multiplex on the basis of the IS-95 document. This technology allows us to make a more rational use of the radio frequency spectrum of a channel.

Internet. I should like to dwell in greater detail on the successes of Internet. It is the most powerful and fast growing telecommunication network of the present time. Within a comparatively brief span of time Internet has made a big stride from a network of merely an institution or an agency to a worldwide information telecommunication infrastructure.

At present 75 countries of the world have access to Internet, and another 77 have been provided an opportunity to be connected through electronic mail to the worldwide Usenet news network, which allows subscribers to exchange information on different technical matters.

According to *Financial Times,* about 40 million users are linked by more than 40 thousand networks in Internet today. A new network is connected to Internet every 30 seconds, and 1 million users appear every month. It is most likely that by 2000 the number of Internet users will exceed the 100-million mark.

Internet appeared after a project was launched in the mid-1970s by the Defence Advanced Projects Agency DAPRA of the U.S. Defence Department. Invited for the project were the research and technological resources of the university, industrial and governmental laboratories of the United States. The telecommunication infrastructure was designed together with the National Scientific Foundation (NSF), the Department of Energy, the Defence Department, the Department of Health and Human Services, and the National Aerospace Agency (NASA). The international network which appeared as a result is called connected Internet, DAPRA/NSF Internet, TCP/IP Internet or just Internet.

Internet today is a transnational infrastructure uniting a large number of various computer networks working on most diverse protocols, linking various types of computers and effecting data-transmission along telephone cables, optical fibre, and radio or satellite channels.

The main criteria for a computer's access to Internet are the use of the TCP/IP protocol for inter-computer exchange, linking to any global network and observance of definite regulations on addressing and routing.

Internet is arranged according to a hierarchic principle. At the lower level of the hierarchy are the local area networks linking together the computers of individual users, and at the upper level is the global infrastructure called Internet with various networks within it consisting of millions of computers on all continents.

Internet has no administrative body controlling its entire infrastructure. There is only a number of fairly authoritative committees acting on a voluntary basis and formulating general recommendations on the principles of network operation.

Internet offers the following classes of services:

- electronic mail;
- news and conferences services;
- access to files;
- access to documents prepared according to the HTML standard (World Wide Web — WWW);
- remote processing of data.

Electronic Mail. Electronic mail has been in existence for over a decade, but only in the mid-1980 did it become widespread in the business world, in research and in education. By the end of that decade it already was one of the most widely used network applications.

According to a study conducted by the Association of Electronic Messaging Association, there were 23 million electronic mail users in 1994, and this number is expected to increase to 73 million by 2000.

WWW. A rapid increase in the number of Internet users in recent time has been largely caused by the development of a language used for describing hypertext HTML documents (Hyper Text Markup Language). The HTML allows to create documents of a flexible structure including text, table, graphic and sound information. The extended structure of an address in HTML references made it possible to place the pages of one and the same document in various Internet servers.

Precisely the mechanism of hypertext references made allowed to unite separate Internet servers into the World Wide Web.

The need to work more efficiently in the ever expanding information space of Internet required the development of special program means of navigation in this information ocean.

Such programs, called *browsers,* should today be installed in any computer linked to the World Wide Web. With their help the user gets access to the WWW servers and receives selected HTML documents at its working station, and viewing, editing and printing them.

Further evolution of telecommunication technologies will evidently be determined by the following factors:

- increase of the speed of information transmitting due to the ever increasing capability of broadband lines and the general use of optical channels;

- developing intelligence of information transmission networks;
- a growing number of users and their mobility caused by breakthroughs in the microelectronics industry and the resultant cheapening and miniaturization of terminal means and the use of wireless communication equipment.

Speed. High speed is necessary for transmitting images, including TV pictures, for integration of various types of information in the multimedia context, and for interconnection of local, city and territorial networks.

Intelligence. The growing intelligence of networks is ensured by the use of microelectronics and software in each individual network device. Such intelligence makes networks more flexible and reliable, increasing their capability and facilitating control of global networks even in different media.

An intelligent network makes it possible to use a large number of services both for the user and the network manager. One of the key factors is that a network offers an easy and dynamic system of orders and a configuration in keeping with the user's changing requirements. The user's role, too, is changing radically from a passive user to an active client.

A Large Number of Users and Their Mobility. Wireless means and miniaturization lead to a global spread and mobility of terminal equipment and terminals and, therefore, to global mobility and ubiquitousness for their users.

Wireless digital devices may have a great and decisive effect on the market which is still dominated by analogue devices. Digital devices, such as the CT2 (The Second generation of Cordless Telephone), the DECT (Digital European cordless telecommunications), the GSM (Group special mobile), the CDMA and the PCN (Personal computer network) have marked big progress towards data-transmission networks and multimedia. The miniaturization of electronic devices, the increasing spread of PCMCIA standards (Personal Computer Memory Card Industry Association) and cost reduction lead to the development and wider use of the terminal systems owned by users.

In mobile communication a growing role is played also by satellite systems. Some projects, as, for instance, the *Indium* project of the Motorola company, envisage establishing worldwide global communication networks on their basis.

Telecommunication (and information) technologies, which in the near future will have a decisive impact on the following developments:

- *Optical technologies* (SDH/SONET):
  — the increase of speed and lowering the cost of access to a network and, consequently, the increase in the number of users.
- *Broadband channels* (B-ISDN):
  — a possibility of transmitting diverse information along one and the same channel and, as a result, an increase of the speed of operation and intelligence of a network.
- *Single technology of multiplexing and commutation (ATM):*
  — the increase of network intelligence.
- *Methods of compressing information.* Methods of coding and compressing information will have a key role to play in the evolution of broadband networks, making it possible to increase immensely the number of transmitted information flows, thereby providing a possibility for transmitting multimedia, television and other information of high quality.

The following compression standards may be regarded as the most significant ones: MKKTT recommendations of the H series, JR.EG standards and the group of MPEG-1,2,3.4 standards.

- *Commutable LANs* (Fast Ethernet, FDDI, FDDI II, ATM)
  — the increase of network capability and intelligence.
- *Digital wireless communication*
  — the increase of mobility and the number of users.
- *Network inter-operability* (Java);
- *Universal access to Internet (WWW) services.*

2. DEVELOPMENT OF COMMUNICATION FACILITIES AND NETWORK INFORMATION TECHNOLOGIES IN RUSSIA

The Russian Federation is unique in size, in the variety of natural and climatic conditions, in the number of ethnic groups living in it and in the spread of communication means. The territory of Russia, 17.1 million sq. kilometres large, has 11 time belts and 6 climatic zones. It is populated by about 200 nationalities and ethnic groups numbering 150 million people.

Russia's education system, one of the world's largest, comprises 69,000 general education schools, over 2,600 specialised secondary educational establishments and about 800 institutions of higher education. On the whole, about 40 million people (teachers, students scholars and researchers) are in the education system of this country.

For decades the communications and their infrastructure in Russia have been developing according to the priorities in maintaining the country's sufficient defense capability. For that reason communications were provided, above all, for state administration bodies, the Armed Forces, the law-enforcement bodies, and the military-industrial complex. In was not until the second half of the 1980s that the development of communication networks for common use was looked upon as a priority. At that time also data-transmission networks accessible for the general public appeared in Russia. At present, dozens of such networks are at work in Russia, some of them are of a national level and are linked to the general telecommunication system of the globe.

In the middle of 1996 telephone network density in the Russian Federation (a sign of a development level of any country) reached 17 telephone numbers per 100 people, which corresponds to the present economic level of this country. To compare: telephone density in industrialized countries is, on the average, 47 per 100 people.

To establish a modern telecommunication infrastructure on a vast territory of Russia is hard indeed. This task is being accomplished in three directions:

- work on large-scale national projects;
- development of, and support for, regional telecommunication projects;
- activities of non-state organisations in this sphere.

Russia's primary communication network is being developed in accordance with the "Inter-Related Communication System" concept of the Ministry of Communications, the Rostelecom projects for digital channels being its major component. It is safe to say even now that, as soon as the construction of the Russia-Denmark, Russia-Japan-South Korea and Italy-Turkey-Ukraine-Russia telephone lines and the Moscow-Khabarovsk digital radio-relay line should be completed, Russia will be in the world telecommunication circle.

The fulfilment of the inter-agency program "Establishment of a National Network of Computer Telecommunications for Science and Higher Education" is of major significance for education and science. Taking part in the program are the Ministry of Science, the State Committee for Higher Education, the Russian Academy of Sciences and the Russian Fundamental Studies Foundation. The programme is to be carried out by 1998. Its purpose is to create a basic telecommunication computer hardware and software medium ensuring a rational integration of the operating computer networks and providing conditions for mass access to national and world information resources and ensuring an efficient exchange of information flows and the development of national information resources, including databases for priority directions of fundamental science and higher education.

The program includes over 100 projects and its total financing is over 200 billion rubles.

The carrying out of this program and of the initiative of George Soros on connecting major peripheral universities of Russia to Internet will result in establishing telecommunication networks for research and higher education in a large number of Russia's regions.

In the framework of this program a Moscow Support Network is being established in the Russian capital. It will consist of Northern and Southern parts. The latter, uniting mainly research and educational centres, is already in operation.

Linking to a support network can be effected by different methods, depending on the available resources and equipment:

• through commutable and selected channels of a common-use telephone network (speed up to 28.8 Kbps);

• through specially arranged selected digital channels (the speed, 64 to 2,048 Kbps);

• through a segment of a local area network LAN (the speed, 10 Mbps).

These methods may be regarded as standard for connecting research and educational organizations to regional networks.

The association of Russian research and educational organizations that are the users of the electronic data-transmission networks established in 1992 - RELARN (Russian Electronic Academic & Research Network) - is developing telecommunications for research and education. Payment for traffic for the association's member organisations is subsidised by the Ministry of Science and other agencies. The subscription points of the RELARN association are connected mainly to the Russian section of Internet (Relcom, Demos), due to which subscribers may have access to the international resources of these networks. At present RELARN has about 1,000 connected subscribers.

Now I would like to go over to regional telecommunication projects. The interest in establishing regional information and telecommunication computer systems was beginning to show in 1992, and in 1994 it was clearly pronounced. This interest was encouraged by the growth of market-economy relations in Russia, which sharply increased the need for reliable information delivered in due time.

At present such networks operate commercially in 10 to 15 regions of Russia. Most of the equipment installed in them use the X.25 Protocol. As a rule, a standard set of information services is offered in these networks — electronic mail, remote access to databases, file transmission, and linking to other networks. The subscribers of these networks are regional banks, state administrative services, some commercial organisations, and users. Networks of this kind are fairly profitable, and their cost is compensated within 18 to 24 months.

The practice of using regional networks shows that already after 6 to 12 months the demand for the quality and the amount of information services increases. This pertains, above all, to the time during which information reaches the subscriber and also to access to Internet. As a rule, most subscribers prefer to get information on-line.

The development of the market of telecommunications in Russia is notably influenced by the activities of non-state organizations, and also foreign firms. Thus, the Italian Italtel firm is active in developing the telephone network in Siberia, the Swedish Ericsson is supplying telephone stations for Russia's regions, and German Siemens is modernising the telephone network in Kaluga.

About a dozen data-transmission networks using various primary networks (satellite, wire and radio-relay communication channels) have been established largely through the efforts of non-state organizations. Among the bigger ones are Sprint, Infotel, Rosnet, Rospak, Relcom, and some others. The Business Networks of Russia project is at a blueprint stage. Most of the networks used are purely commercial, providing information services for a fairly high price. The most popular network offering services for a moderate pay is Relcom.

The communication systems and telecommunications in Russia are developed with the use of advanced Western telecommunication technologies. At the same time, national technologies, which have become accessible due to conversion of defense facilities and are adapted to Russia's conditions, are used extensively in this country.

CONCLUSION

In my speech I wanted to draw your attention to the idea that all the latest achievements of modern information telecommunication technologies, which I have tried to describe here, should be used in disseminating informatics in science and education.

At the same time, I should like to stress that the experience of Russian experts in the development and application of telecommunication technologies may prove useful for other countries having common specifics with Russia, such as vast distances between populated areas, insufficiently developed networks of primary communication channels, and the need rapidly to reach the level of advanced telecommunication development.

TELEVISION-COMPUTER INFORMATION TECHNOLOGIES AND DISTANCE EDUCATION

I.N. Pustinsky, Yu.P. Ekhlakov, M.I. Kuriachy, V.V. Kruchinin, O.V. Ravodin

TOMSK STATE ACADEMY OF CONTROL SYSTEMS AND RADIOELECTRONICS (TASUR)
(RUSSIA)

The continuing advance of information technologies has led to an increasing number of higher educational institutions using these technologies in the learning process. Apart from those, recently, television-computer information technologies have come to be applied, which extensively utilize television facilities of information processing and communication.

The present report reviews the results and experience accumulated by the Tomsk State Academy of Control Systems and Radio-Electronics *(TASUR,* Russia) in the course of its research in this field conducted with a special view to distance education.

The intended goal is extending the market for educational services in the West Siberia region by setting up a distributed network of branches and organizing in-house training process for the first and second year students. At present, the Academy has branches functioning in seven cities: Surgut, Nizhnevartovsk, Sayanogorsk, Yakutsk, Yurga, Noyabrsk, and Nefteyugansk, with the total enrollment in the full-time and correspondence courses exceeding 500. The biggest branch is in Surgut, with the number of students around 250.

The technical base for implementing distance education comprises:

- the Academy corporate computer network CCN TASUR (information-communications unit in three academic buildings, local computer networks in these buildings, local computer networks and remote terminals in the Academy branches);
- a television-computer system complete with the facilities for building and transmitting Teletext programmes and computer data via television communication channels;
- a satellite television receiving and transmitting complex.

The basic link within CCN-TASUR are the information and communications blocks which integrate local circuits into a common informational environment and are a gateway into CCN-TASUR and the global networks. Each block includes a file-server controlled by OS Novell Netware 3.12, a communication UNIX-system controlled by OS UNIXFreeBSD 2.0.5, and learning UNIX-systems controlled by SCO UNIX.

The communications UNIX-system provides for interaction between CCN-TASUR information-communications unit and between these units and the communications units of other networks, and acts as a gateway between the LAN of each of the academic buildings and the other networks with an access to Internet.

Apart from the above functions, one of the information-communication units is responsible for external interaction with other networks. It also comprises a modem control panel for remote access over switched circuits, circuits for the city-area informational environment, IP-circuit to Novosibirsk and Moscow, *Iceberg* facilities of the *Inmarsat* network with a satellite telephone line, a node of the international non-commercial FIDO telephone network. The network nodes are linked together via three replicated variants - a telephone line through shortmodems on the basis of TCP/IP protocols; a 10 Mbit/sec transmission speed radio channel; switched telephone circuits using standard Hays-modems on the basis of UUCP protocols.

The internal circuit infrastructure of each academic building's LAN is two-level: inter-server segments of the local network link the servers of the Academy sections and classrooms. All local networks within each building are running on the Internet basis and using the protocols IPX/SPX and TCP/IP.

The total number of currently operating local subnets of CCN-TASUR is 25, and the number of workstations is around 320.

The creation of the software and technical platform for the numerous informational resources supporting the educational process allows us to speak of a possibility of their extensive and effective application for the needs of the learning process, in particular, for organizing elements of distance education (DE).

The following facilities are available to the users of the local networks (with respective rights of access, needless to say):

- access to all LAN files and UNIX-servers;
- access to electronic mail: local (within an academic building) and global;
- access to Internet and FIDO via the gateway;
- using ETELNET protocol for linking a remote terminal to any UNIX-system within a local network or Internet;
- operation in the FTP mode for exchanging information (data files) with the clients linked to Internet;
- access to the electronic board bulletin (NET BBS);
- using the multimedia distributed information system on the basis of the World Wide Webserver.

Given appropriate computer hardware and software resources, WWW technology is a very good structural kernel for a DE system, extending by far the BBS qualitative and quantitative characteristics.

DE accessible electronic communications external with regard to the local networks could be broken down into the following three categories:

• using Internet services and protocols;

• using FIDO-NET mail;

• using direct modem links over switched circuits (UUCP protocol support).

A learner chooses one of the electronic communications channels proceeding from its technical capabilities, while the TASUR communication nodes potential allows to support all the above listed communication categories on the basis of available facilities. From the point of view of scope of possibilities and availability of all the protocols and communication technologies (WWW included), the application of IP protocols is preferable. The network users linked to FIDO can use FIDO electronic male to exchange information with a remote educational service irrespective of the territorial location. If a direct modem link is used, the user can work with the educational network BBS via its modem input and has available an information-reference system and two-way data files transfer.

Of special interest nowadays would be research toward finding a way to increase the number of computer data users. This concerns, in part, dissemination of information over Internet networks to many users simultaneously. Most of the communication channels today use telephone lines. However, considering the requirements placed upon communication transmission channels, such as high transmission speed, great volumes of transmitted information, stability/reliability of the communication channels, etc., it is possible to find ways of using television communication channels for the transfer of additional educational information (AI). This will not raise its cost or affect the quality of data communication services. A distinctive feature of the existing television broadcasting network in Russia is its high centralization degree and hierarchical structure, which corresponds to the structure of information flows in the radial dissemination of computer data flows.

As computer technologies find ever more applications in television broadcasting, the two become increasingly convergent. The trend for convergence can be traced in a number of advanced technologies, such, for example, as *Intercast*, *Smartcast*, *DirectPC* and others, which take advantage of Internet's interactivity and the high communication capacity of the television broadcasting channels.

According to expert estimates, as soon as by the end of this year a considerable number of personal computers will be equipped with facilities for receiving additional information over television channels, and a number of major television broadcasting companies, CNN and MTV among them, have announced their support for the Intercast technology of additional data transmission.

The Academy based its research into the technology of radial computer data transfer on the information system TELETEXT. Its advantage is high transmission speed, simultaneous communication with a considerable number of nodes, long-established standard for data transmission. By this day, the Academy has developed two basic components of the system.

1. A trasmitting centre located at a short distance from the broadcasting television centre and possessing a distributed communication network, with information coming over telephone, telegraph and other communication channels. Apart from the computer equipment and communication services, the facilities include some specialized devices providing for the coding and input of the transmitted information into the television signal.

2. The network nodes, equipped with receivers on the basis of the personal computers with specialized receiving-decoding units. Receiving is possible in any location within the region, provided that television broadcasting can extend to this region in general.

General features of the system:

• transmission of data over an ordinary broadcasting television channel by inserting data during the blanking pulse of the frame scan interval of the television scan (up to 16 lines per frame are occupied), with the transmission of additional data occurring in one frame with the main signal, but with no interference whatever;

• high transmission speed;

• simultaneous data reception by all the network users;

• transmission of great volumes of data (up to tens of megabytes an hour) combined with a high communication reliability;

• a distributed network and high automation level of the information collection process at the transmitting centre, including over telephone lines;

• full support to information transmission and reception in the teletext frame standard (WST, level 1.5);

• permanent feedback control over the transmission quality, exercised by decoding device;

• possibility of dedicated transmission.

Another and relatively independent application of this technology provided by the use of air and cable television for data transmittal and reception in the system of distance education. In this case, data is available to a student over telephone broadcasting channels in a specified mode or as ordinary teletext programmes transmitted eiyther together with standard television programmes or as video-films. By using an ordinary television receiver linked to the data source, it is possible to create an interactive mode of student's communication with data bases and other information, the choice of which becomes available to this student via the system's feedback.

Let us make a brief review of the television-and-computer system created by the Academy researchers for data formulation and transmittal over telephone lines.

The configuration of this television-and-computer system is comprised of facilities for the formation and transmission of teletext and computer data, local area network, video-studios for on-line and off-line editing, a computer graphics studio for building and broadcasting multimedia programmes in the *Invision* mode, television cameras for recording and archiving of teaching courses segments, and a television receivers network with a system for receiving additional text information of the teletext type. Data communication to the users' television receivers can be carried out either over a cable network or in the air broadcasting mode (with the feedback achieved over telephone lines).

The system integrates the best of television, computer technologies, and educational facilities, and provides for the operation of the following distance education functions:

• regular educational programmes for school children, students, and adult learners using the video materials banks currently available in Russia;

• video courses for extra-mural preparation for university entrance examinations;

• discussions, informational advertising, and other programmes of scientific and educational character;

• compilation and transmission in the teletext frame standard of various informational, scientific and educational blocks for organizations and the general public.

At its simplest level, the technical equipment of any user of this system must include a television receiver with a decoding unit. This type of workplace allows to browse videocasts and retrieve additional information via teletext options.

The possibilities are far greater for a workplace equipped with a personal computer besides the above devices. They include archiving, fast search, processing and reproduction of great volumes of data.

The fully equipped working place, while providing most of the functional possibilities, comprises such additional equipment as a modem for data exchange with the Academy corporation computer network. A user, in this case, can order specified types of educational materials, send back the results of educational assignments, etc.

Presently, TASUR specialists in Tomsk, working with the assistance of the independent *TV-2* network, have launched a DM wave-band television channel (Channel 22). A programming-machinery complex has been set up on this basis of this channel for transmission of additional information (teletext and computer data) over television broadcasting channels. Beginning with 1995, the receiving devices have been in exploitation at two television channels of the city of Tomsk. The complex uses data transmission speed of up to 100 Kbit/sec.

The satellite television transmission-and-receiving centre provides for transmission and receiving of the television signal from the geostationary orbit satellites. It comprises a hypersensitive receiving device, a 1.5 Kwt/h, and a 4.5 m parabolic antenna.

Today, the centre presents an integrated satellite telecommunications node comprised of *Galaktika-1* receiving and transmission complex, the terminal *Iceberg* of the *Inmarsat* satellite communications system, the DM wave-band transmission television centre (Channel 22) and an antenna field receiving signals in different wave-bands, an information studio, and a programmes studio of the city of Tomsk as an interregional science and education centre.

Since the inception of the technical centre, in 1993, the TASUR employees have actively contributed to the development of the regional satellite television project *Yenissey-Sibir*, and together with the US firm *Datron*, they were employed in the international expertise of the regional satellite communications system Sibnet international project. They are currently working jointly with the company STS (Moscow) on putting in operation of a digital television complex of MPEG-2 standard via a satellite retranslator *Gorizont* (53° EL). The centre also provides for retranslation of the programmes run by various television companies to the audience in Tomsk via the centre's own transmission node.

This television-and-computer technology, together with the supporting facilities, have the potential for setting up a full and extensive system of distance education in the Siberia Region.

The distance education system combines the basic principles and approaches of correspondence education with the elements of full-time (day-time) education. The principal stress is put on the learners' independent studies of the subjects of education. However, despite the general similarity, the proposed education technology is cardinally different from the system of correspondence education. This difference lies in the fact that a DE user can be in permanent communication with a college or university, obtain information in desired field on request, and get fast advice if a need arises to address a problem, while the tutor can check on the learner's results at any given moment.

It is pertinent to single out two principal sets of problems to be addressed in the establishment of an educational process: education organization and the methods and techniques applied.

The problems of organizational character stem from the need to ensure a synthesis of the specific system of control over the learners efforts, a synthesis of the structure and algorithms of DE functioning which ensures optimal learning conditions for the learners and teachers alike. Much importance attaches to the matters of administrative character designed to ensure effective and reliable functioning of the DE system.

The DE system is organized as a base educational centre (TASUR), regional users (branches and individual learners), and a technical communication system.

The base centre comprises the following divisions:

• the methods and techniques division - responsible for development of instruction methods and specific automated study courses;

• the consultation division - for support of the "hot lines" (including television lines) in the real time;

• the organization division - comprising the personnel department, accountants, etc.

Similar groups may be set up within the branches if a need for them arises.

The programme system *Administrator* occupies a special place in the DE system. Its function is control of the educational process, management of data bases and flows pertaining to the process and methods of education, and adaptation of the instruction process to the growth of the learners' knowledge and providing the users with information at the desired level.

Below we describe a version of the *Administrator* system, including the following functions:

• the teacher's compiling of assignments;
• the transfer of the assignments to the student;
• the student's fulfilment of the assignments;
• the teacher's checking the results;
• the teacher's comments and evaluation;
• delivery of the evaluation results to the student;
• recording the student's mark in the progress register.

The system's authors formulated the principal requirements placed upon its operation as follows:

• the learner's answers to the offered tests and assignments should be transmitted via electronic mail as the most universal means for the assignments and answers transfer;

• the learners' answers may be transferred as an archivised file, containing the executable files as well as the textual and graphical comments;

• the system should register the fact of transmission and reception of an assignment and the student's answers;

• the text results of the student's work should be preserved together with the teacher's comments;

• the message text (the teacher's answer) contains the student's answers and the teacher's comments;

• the qualitative evaluation of the student's results can be made using various criteria depending on the weights assigned by the teacher;

• the results' evaluation (of the rating type or in accordance with the accepted five-mark grading system) is entered in a specific discipline's progress register;

• the maintenance of an electronic progress register should envisage the following functions: editing of the disciplines, topics, study groups, student enrollment, task numbers and respective rating assessments, as well as review of the register and search for any crosssection information (subject, theme, group, individual students);

• the formulation of an assignment for a student means that the teacher can introduce a test assignment in any subject or discipline;

• the results should be chacked against the correct answers which the teacher keeps in a separate data base.

Stemming from the requirements as described above, the system's programme implementation provides for the realization of the following functions:

- e-mail analysis;
- accepting the learners' answers to the tests or problems;
- registering of the teacher's comments on the learners' answers;
- formulation of the teacher's reply;
- maintaining progress registers by particular disciplines;
- formulation of test assignments for control and questioning;
- maintaining a general achievements register.

Work with the personal mail-box begins with message cracking by an analyser which sorts out the messages received via electronic mail. The algorithm of message handling is based on checking the letter's header and the system data accompanying any E-mail message.

If the sender's name is found in the learners base, the message contents is analysed.

The executable files or graphic frames are entered in the special teacher's directory for subsequent verification in respective media. The teacher's personal mail remains in the mail-box for individual review.

The student's answers may be presented as one of the three types of answers or a combination of the three: segments of a text, set of graphical frames, or executable file.

The teacher checks the student's answers in his own time by choosing the data processing option. This function allows to scan the student's message on the screen and insert the teacher's comments.

The checked test together with inserted comments is presented as the teacher's reply to the learner. The test results are entered in the electronic learner's progress register. The identification of the learner, subject, assignment number, and grading system is carried out automatically. Achievement registering includes all the functions designed to support data verification and validation. It allows the teacher to do the following:

- add new assignments, sets of assignments, disciplines and topics, and decide on the maximal assessment rating for each of the assignments;
- add new groups of learners;
- edit any of the above-listed objects;
- purge any object while preserving the archived results;
- scan the crossection results in any of the chosen objects and get a printout of the document.

The express-testing information technology relies oh the idea of building a base of test assignments and learners' answers. The answers may be kept separately from the system, in the teacher's disk, for example. The assignments can be entered at the crossection of disciplines and topics of the chosen subjects. The testing pattern of questioning and evaluating the answers allows to decide on the number of points (the grade) scored by the learner in accordance with the chosen evaluation scale.

The questioning procedure begins with the learner's identification and ends with the entering the scored mark in the progress register. The testing system is useful as an instrument of the learner's self-training and of express-assessment of the learners' achievements in individual subjects of the teaching programme.

When performing an individual assignment, a learner can apply to informational resources of various types. With this purpose in view, TASUR have developed a specialised *Feya* source system intended for creating various programmed instruction senvices (PIS), computer manuals, practical studies aids, control tests, examinators, etc.

The system's functional structure comprises:

- a graphic vector editor for the input and editing of the graphic teaching information with availability of inserting PIC and PCX format pictures;
- a paragraph editor operating in the graphic mode and providing for changing paragraph size and layout, line interval, font and colouring, for paragraph formatting, and for importing text files created by other editors;
- a menu installing editor providing for creating menus of various kinds (5 types of the menu cursor, menu elements of various sizes and screen layout, - practically unlimited number of elements in a menu);
- testing and benchmarking editor allowing to create test questions with three answer versions: injector (keyboard answers input), menu, viewport;
- object management editor for organization of various branching, cycles and transfers depending on a learner's answers or menu options;
- music editor;
- compositor programme;
- executive programme.

Methodologically, an educational programming system within the *Feya* system is an aggregation of interrelated frames. Each frame is comprised of a fixed number of various objects - graphic, text, music, supervision, etc. (some 80 object types altogether). A frame proper presents a succession of actions, a programme describing one act of the overall script of education. The basic idea behind the system's operation lies in the fact that a user applies various processors to create a programme without any implicit recording of this programme. For example, he applies the graphic editor to draw rectangles, ellipses, and lines, requests viewports, etc., while the system automatically records these actions in a frame. Thus, we can talk of two types of viewing for the user: *the first* is external, with the data presented at the terminal display, i.e., the educational information frame, and *the second is* internal, i.e., constitutes a programme describing certain actions leading to the compiling and use of the educational information. This approach to educational information organization allows to achieve the following:

- ensure that the users who are not familiar with programming can compile computer tutorials, while the users who are familiar with programming can create relatively sophisticated educational scenarios;
- obtain a fairly compact presentation of the educational material, which is rather important in view of the fact that the educational materials can be of a fairly considerable volume.

Due to these two features of the *Feya* system has an advantage over similar systems. The main stages in the technology of developing a programmed instruction system present themselves as follows:

- determining PIS goals and objectives;
- creating a general scenario, partitioning of subjects, topics and lessons;
- breaking down the general scenario into elementary acts and their presentation as frames;
- initial stage in PIS implementation on the basis of the system:

a) font review and selection;

b) selection of an interface for scrolling, access and transfer to subjects and topics;

c) selection of the evaluation system;

- compiling an archive for application in the course of the learning process.

The described version of the system:

- ensures the network mode operation of the executive programme in the local area network, with a special protocol, maintained for every learner, for recording the learner's name, surname, and patronymic, date and time of the start and completion of the operations, the contents and length of time taken by each answer, and the resulting mark scored by the learner;
- is supplied with security means protecting the PIS developers' copyright and making the correct answers and protocols secure against any access by the learners;
- possesses an extensive methods and techniques support: a special practical aid was developed specially for the purpose of considering the practical examples demonstrating the system's possibilities.

The technology of developing a programmed instructional system is incorporated in TASUR and was handed over for implementation in a number of higher educational institutions in the sities of Tomsk, Novossibirsk, Krasnoyarsk, and Abakan.

The results presented in this report pertain to the initial stage in the introduction of television-and-computer technologies to support distance education. In our view, further research should sign priority to mastering and application of the WWW and BBS technologies for providing a remote access to the information resources and education support programmes; to enhancing Teletext *programmes transfer rate; to providing organizational support and the development of the methods and techniques required for distance education and to building up informational resources in various fields, subjects and disciplines*

Commission III

REGIONAL COOPERATION IN THE CONSTRUCTION OF INFORMATION NETWORKS

Ella Kiesi

UNIT OF EDUCATIONAL TECHNOLOGY
NATIONAL BOARD OF EDUCATION
(FINLAND)

The goal in Finland is to link all schools and educational establishments directly to international information networks. Schools have used telecommunication links since 1986. This link has mainly been a slow modem linked to one of the school computers. Its advantage was that it demanded only a very small initial investment. But the use of telephone lines is costly and may amount to considerable sums, if kept open for several hours each day.

Another thing is that one link per school is not very useful in teaching. It was soon realised that of the school wanted to make use of telecommunications and Internet in teaching, it bad to have several computers linked to a network. But the fact that costs grow with each minute limits their use very efficiently. Therefore the aim was set at fixed monthly costs.

Schools should not be only users of information in the Internet, they must also produce information. To make this possible, schools need servers of their own. Direct links, with their routes, servers and running costs, are so expensive, however, that all schools cannot afford them. This is why we started to develop a model in which several educational institutions arc linked into a regional network. It was not seen necessary to create a nation-wide school network, because there are many commercial networks which operate on the national scale.

At first, regional networks evolved around technical colleges, because they had better hardware than others, for instance UNIX computers. Similarly, they had Access to the expertise needed for the use, of information networks and for systems maintenance.

A network is created when local school networks arc linked directly to a server via routes. Distant schools can use ISDN links. Even an ordinary modern may be enough for smaller schools. The school which is the main server is linked to a commercial network via routes. At present the links are mostly wideband ATM links. As the cost is shared, it remains reasonable for each participating school. A network may also have several servers, but it is best to start with only one and acquire new ones according to need.

Practice has shown that a regional network also promotes other forms of cooperation. For instance, institutes can arrange joint in-service training for teachers. In the same way, schools can pool resources in computer maintenance; it would be far too expensive for each school to hire a technician for the purpose. Networking also encourages schools to set up joint projects for exploring new ways to use computers in teaching.

The first regional networks were set up in northern Finland a few years ago. Now every fourth educational establishment is linked to a regional or other major network. There are some twenty regional networks in Finland, and plans for at least another twenty. Their size varies from 20 institutions to 70. Most school networking in the future will be done by means of regional networks. The state subsidies to be granted for networking from 1995 to 1998 will be largely used to create regional networks.

COMMUNICATION INFORMATION AND TECHNOLOGICAL INFRASTRUCTURES IN UKRAINE IN THE TRANSITION PERIOD

Alexei Dovgyallo

UNESCO CENTER FOR RESEARCH AND TRAINING,
GLUSHKOV INSTITUTE OF CYBERNETICS,
UKRAINIAN ACADEMY OF SCIENCES

The paper addresses intelligence in educational technologies for the conventional and remote case, and the tendency and need for cooperation. This study was supported by the European Commissions, Copernicus Program in cooperation with the Twente University (Netherlands), the Exeter University (UK), the Sofia University (Bulgaria) and the Kaunas University (Lithuania).

I would like primarily to state the Ukrainian position regarding education and informatics. The Ukrainian position is transitional between developing countries, whose objective in the informatization of education are limited, and the developed countries, which pursue complex or advanced goals. In particular, our problems are associated with introduction of intelligence in educational informatics, with the development of theories and introduction of some sophisticated technologies in education. The facts is that our Institute in Kiev, Ukraine, has a long computer record. In 1951 on the basis of the Computer Center of the Academy of Sciences, from which our Institute later grew, the first computer in Europe was developed, and in 1963 the *«Mir»* computer, which in our opinion, was the first personal computer. Hence, our studies in informatics and education, on the one had, need the development of infrastructure and injection of communication and information technologies, and, on the other, hand, in case the available resources of educators, scientists and teachers are supported, we are ready to develop some fairly complicated technologies of education and introduce them. My paper will be, on the one had, an introduction into the existing problems, and, on the other, demonstration of the potential of the countries of the former Soviet Union in the development of informatics in education.

Thus, the Ukrainian national program of informatization has the following top priorities: Internet literacy and support of communication and information technologies, establishment of a network of research centers supporting distance education, creation of computer-based didactic laboratories for uninterrupted training and retraining of teachers, more exactly, attachment of teachers to such laboratories, and, finally, one the Ukrainian priorities are intellectual technologies for the conventional and distance education.

What is intellectuality in education? This is primarily a combination of technological and spiritual aspects in the study subjects. In particular, the Chairman of our Congress *Professor Kinelev discussed in detail* ecological literacy, which can represent the unity of technological and spiritual aspects in general education. A very important point is national aspects in international education. Educational simulation of subject areas is also a manifestation in intelligence in education. The new aspects of cognizing activities are primarily the development of data bases and expert systems by students for the study fields, i.e., a student is not to solve a problem or to answer a teacher's question, but is rather to develop a small expert system of his own, which reflects his knowledge of the study material rather merely solves a problem in a conventional manner or answers the teacher's question. Subsequently, the teacher assesses the knowledge of the student on the basis of the efficiency of the operation of the assessment system that he developed. This project was supported by UNESCO and was implemented in schools and higher educational establishments of Ukraine, Syria, Kazakhstan and Azerbaijan.

Another interesting trend associated with new cognitive activities is the conceptualization of vizualization of knowledge models performed by the students. Very essential in this cases is the multimedia representation of the study material. These problems are still open, and I could only give you the above examples.

Intelligence in the education method is adaptive testing and learning of students. We are now doing some interesting work jointly with Osaka University (Japan) on the ontology of study problems and on the development of student models.

Another point of intelligence in learning methods is the dialog method of education when both the student and the teacher control the process of learning. Some the these Intelligence indices are implemented in a remote module course in communication and information technologies, which is based on the use of WWW. This work is also performed on the Copernicus project, involving the Netherlands, United Kingdom, Bulgaria, Lithuania and Ukraine. This course as it is can be turned to in the Web and take a look at it. It will be implemented, more exactly, subscription to it will be in September. The module nature of this course is manifested in the following. This is merely "Internet literacy", then come course for engineers and a module for the teacher. To give you an idea of this course, I shall refer to Vladimir Kinelev, who said in his address that the time of fundamental knowledge has also come in education. We have been working along these lines too, and for this course we have developed a model of flexible distance education, which I shall try to show you. A general concept of intelligence in education and informatics has also been developed.

The model is the following. I heave no time to discuss each section of the model, but it has 5 basic parameters, including the basic communication system, being used, educational media, flexibility parameter, organization situation, and teaching and learning parameter. As you see, these parameters have, in their turn, their subparameters and values. This model is only the first attempt. Let us illustrate this with the «educational media» parameter. The parameter values have already been stated- For instance the text-based educational media comprises printed material, electronic mail, text-based computer conference. Interestingly, the tendency is text-based in multiple media, i.e., when there exist different representations of the same study material but in integral form, multimedia is integral. And, here I cannot deny myself the pleasure of mentioning cognitive graphics as a media, which was developed in Russia by Dmitrii Pospelov and used in Ukraine by Yurii Valtnekh. Here is the idea of cognitive graphics implemented. In this model this classification has been completed. What is it needed for? Why do we need a model of the above-described type? Firstly, for the unification of the description of the existing courses, in order to see, more or less definitely, what type of remote learning or education has been implemented in a definite course. As shown by experience, this model is a good support for designing and development of new course. This model permits designing a more accurate experimental research of courses, when we establish exactly what parameters in the control and experimental group would be similar and what parameters will differ. For the countries in transition as is Ukraine, such precise techniques of educational research are somewhat new. Finally, this model can be used for the designing of the data base structure of some assessment system, which would be helpful to teachers and designers of the new course in developing new remote techniques suitable to the specific purposes of learning and teaching.

Another line along which we continue working — we cooperate with the Research Institute of Higher Education of Russia — is the development of the general concept of inclusion of intellectual properties in educational technologies. This concept is stated below. Module, multifunctional and multimedia exposure, representation and designing as well as effective local and remote dissemination of knowledge to attain limited and integrated objective of the education, in particular for the provision of cognitive and creative capacities of the students. In contrast to Prof. Kinelev, I believe that this course, is, presumably, more efficient than writing a fundamental education theory in each subject. Perhaps, it would be better to develop the cognitive and creative capacities of the student, who would later gain an insight in the subject under study at the needed level, teaching cooperative skills, providing interaction between work, research and training. These and similar points are stated in a number of our publications, unfortunately in Russian. These are primarily the dictionary *Computer Technologies for Education* a two volume publication, which put together over 600 papers from 120 specialists from Ukraine, Russia, Poland, Germany, Chekhia, Slovakia, Rumania, Cuba, Hungary, Bulgaria and other countries. It was published in 1992 under the auspices of UNESCO, but the theoretical part and the main approaches, which I stated today, in principle remained at a good level. Other publications have been prepared, I will distribute to you information about these works with pleasure. This is in English: *Media and Telematic? Technology for Education in East European Countries.* This is a sort of follow-up of this reference book, which can be demonstrated by my colleagues from the Institute of Higher Education of Russia Yu.I.Lobanov, who is present here. As to me, I am ready to distribute, by way of souvenir, the volumes to all who understand Russian. There are also four copies of my paper available, but in a more complex form.

The original is presented in Russian

RUSSIAN INTERNET AND NEW TECHNOLOGIES IN EDUCATION

V. A. Vasenin

LOMONOSOV MOSCOW STATE UNIVERSITY (RUSSIA)

1. MAIN GOALS OF TELECOMMUNICATIONS DEVELOPMENT IN THE FIELD OF EDUCATION

Globalization and internationalization constitute one of the crucial trends of world science development today. At present, the most significant research projects in the field of space, informatics and ecology, biotechnology and nuclear physics unite the leading specialists and research centers worldwide. Presentation and rapid exchange of results, the possibility of manipulating the data in a form similar to their natural occurrence in a particular area are becoming some of the most pressing tasks whose solution determines the rate of progress of science and engineering. Higher school is called upon to train specialists for novel scientific areas; not only should they be receptive to new technologies: they must be forerunners of adopting and promoting such technologies. Higher education should not be confined to the training of top-skills personnel at elitist universities: the entire scientific-and-educational community must be given access to knowledge and experience of the leading research schools. Effective solution of these problems lies in the area of using newest technologies currently promoted by the Internet global network.

Information technologies of Internet, using audio, video and hypertext, provide for scientists, lecturers and students access to non-traditional sources of information at any point of the globe as well as to the means of data presentation and manipulation. Computer technologies transform the forms of extra-mural (correspondence) education and a system of upgrading one's skills, develop self-education habits crucial for the entire system of continuous education. The gap between science and education is being closed, the professional level of specialists is rising.

2. STATUS OF INTERNET IN RUSSIA

Computer telecommunications are relatively new in Russia, but they have registered a spectacular growth. The process was initiated at the end of the 1980s by a few projects launched by major research-and-educational centers (Kurchatov Institute, Institute of Space Research, Lomonosov Moscow State University (MSU), VNIIPAS) backed by state bodies (Ministry of Communications, Ministry for Science and Technical Policy, Russian Academy of Sciences, State Committee for Higher Education). The projects grew in number, part of them went commercial, others, financed by the state, were oriented to solving problems for the benefit of science and higher education.

Relcom, Rosnet, IASnet, Demos are among the computer networks that developed on commercial principles. The first academic networks were Freenet, RSSI, Radio-MSU, MSUnet (networks associated with MSU).

However, all these projects lacked coordination, had no proper state financing for academic networks or profit for commercial networks to be able to establish a fundamental environment, basic infrastructure that would allow to promote on that basis a major nationwide project. This circumstance held back the rate of Internet growth in Russia.

The end of 1993 - beginning of 1994 may be considered a turning point in this process, when projects were prepared and began to be implemented aimed at building high-speed channels (over 64 Kbps) linking major research-and-educational institutions, economic regions of Russia, towns or campuses of universities and research centers.

Such projects include RUNNet, Moscow basic network (ISF and RFFI), main network of MSU, Institute of Space Research, Radio-MSU Russia-German Project and, of course, the 50x50 Project of AO "Rostelecom": building a digital fiber optic channel to provide communication among Russia's largest economic regions. Most of these projects were financed by the state.

In 1994-1995, within the framework of these projects effort was made to establish the main transport environment (including the systems of satellite communication, fiber-optic and radio-relay lines), to set up an infrastructure of major computer telecommunication facilities servicing these channels for data transmission across Russia's vast territory.

3. GATES TO FOREIGN NETWORKS

Alongside the development of the base infrastructure, the following supporting gates to major foreign computer networks were set up in Russia: EUnet (Relcom, 1 Mbps), Ebone (MSUnet/RUNNet, 256 Kbps), Dante-Europanet (Radio-MSU, 0.5 - 1 Mbps satellite link, 128 Kbps ground-based), Nordunet (RUNNet, 256 Kbps). Today, these gates constitute the basis for integrating Russia's networks into a global Internet.

4. INTERNET IN EDUCATION

The current computer infrastructure of telecommunications provides conditions for developing fundamentally different information technologies on this basis, capable of enhancing the efficiency of training and research. For example, the use of unique expensive equipment (including high-capacity computers) installed at research and educational centers for studies and training purposes in any of the regional centers in a remote access mode yields a direct economic effect.

The crucial program whose implementation is based on an extensive system of computer telecommunications is the Program of Setting up a Universal System of Distance Education in Russia. Using the best traditions, forms and methods of extra-mural training at a stage of pre-university education, university self-education and a system of post-graduate education; upgrading and re-training of personnel, Russia's system of distance education produces methodologically and technically distributed environment for lifelong education.

Multimedia and intermedia technologies constitute one of the most promising areas of developing information technologies in education based on computer telecommunications. Unlike the traditional linear technologies using data banks and data bases, packages of applied programs providing for purpose-oriented processing of data and presentation of data in a form close to the one used in a particular field, multimedia integrates the aforesaid technologies and incorporate text, graphics, video and sound.

An example of the most promising means of data exchange in science and education in global networks is WWW (World Wide Web) - an information distributed multimedia system based on hypertext. At present, this is the most powerful means on the basis of which distributed information systems in particular fields of science and engineering, teaching supplements, virtual libraries are created.

An important aspect of developing computer technologies for education is organizing interaction in a mode of audio, video and multimedia conferences, using the global networks infrastructure for data transmission. For lecturers of higher educational establishments and heads of the leading scientific schools video-conferences provide an opportunity for disseminating knowledge, views, ideas among the broad transnational audience, research centers and institutions of learning linked by computer networks for data transmission. Movement in this direction is a real step towards expanding the sphere of active impact of science and higher education on the progress of science and engineering worldwide. This is a practical answer to the processes of internationalization and globalization of science and higher education without detriment to national interests of the parties involved, an answer aimed at mutual enrichment of scientific schools and educational systems of different countries.

Multimedia conferences in Russia are still in the making. One of the first was video-conference Moscow (MSU) - Novosibirsk (Novosibirsk State University - NSU) organized on the basis of the satellite RUNNet channel, using free software distributed within the framework of the "Multicast Backbone" (MBone) Project. A few days ago, we organized a video-conference at the request on the Ministry of Education.

MBone tecyhnology is one of the propitious, rapidly developing technologies of Internet. In Russia, this technology began to be adopted actively in the Southern segment of Moscow base network. The first results of this activity were regular translations from the "Computer Networks" Workshop (Institute of Space Research of the Russian Academy of Sciences), a full-scale translation of the IVth Congress of the Russian Union of Rectors (MSU). At present, this work is continued in Novosibirsk, Yekaterinburg, St.Petersburg. However, a full-scale functioining of MBone calls for channels of at least 500 Kbps carrying capacity. The existing transporting structure of Russia's research-and-educational networks restrict She spread of this technology.

5.FUTURE: NATIONAL RBNET NETWORK

Even a brief analysis of the requirements of science and higher education as far as promising information technologies are concerned, indicates the crucil, fundamental importance of promoting the base infrastructure of the National Network of Computer Telecommunications RBnet (Russian Backbone Network). Success in resolving this problem determines the rate of National Netwoks Computer Telecommunication of Science and Higher Education (NNCT SHE) establishment, development and firther promotion of contemporary information technologies.

Many of the currently operated data transmission computer networks use as internal system-forming mains traditional telephone cable lines, usually leased from AO "Rostelecom". Such lines provide a satisfactory coverage of the entire country, yet they are expensive, fail to secure a dependable quality of transmission and, what is more important, high speeds over long distances (maximum 28.2 Kbps, but usually - 19.2 Kbps). Considering the traffic structure and requirements of Russia's research-and-educational centers (including audio, video and multimedia information, text databases and knowledge bases, computer resources), we realize that RBnet requires a transport medium with a speed of data transmission of at least 256 Kbps and with a possibility of its rapid (as the need arises and information resource becomes available) increase of up to 512 Kbps and more.

Analysis of the existing transport medium of Russia's active data transmission networks indicates that at present RBnet structure may use radio-relay and fiber optic lines of AO "Rostelecom", high-speed interregional channels of particular telecommunication companies operating in Russia (Macomnet, Petrocom, Rosnet, etc.), RUNnet and Radio-MSU satellite channels. At present, all necessary conditions are available for establishing on the basis of these segments a base infrastructure of the network on a nation-wide scale: communication among the largest economic regions is provided to a greater or lesser extent, but there are reserves for setting up regional networks, skilled personnel become available capable of promoting and maintaining these networks.

Of crucial importance for the NNCT SHE Project is the concept of base access points. In fact, these structures are analogs of North American NAPs (Network Access Points), i.e. network complexes providing for local exchange of traffic among various service providers as well as (at a subsequent stage) for coordination of routing policy based on the use of route servers.

A distinctive feature of NAPs dealt with in the Program is their close integration with the main units of RBnet. While securing an interregional exchange of traffic, RBnet channels virtually tie up a series of base access points, of which the following are specified at the first stage: St. Petersburg, Moscow, Yekaterinburg, Novosibirsk, Khabarovsk.

A transparent access of regional networks to RBnet and, via RBnet, to global networks is attained through an institutional-and-technical structure, which, using Internet terminology, is called Internet Exchange (IX), i.e. a point for reciprocal exchange of traffic. At present, already operational is Moscow IX located at trunk exchange M9; St. Petersburg IX (Lenenergo) is going through the launching stage. Together, the base access points (including IX and RBnet unit) and the aforesaid main channels are to ensure an optimum mechanism of intra- and interregional traffic transmission within Russia as well as a duplicated escape to international base networks.

The structuring, operation and development of NNCT SHE base infrastructure will largely depend on how effectively foreign experience of networks building and development is accumulated and taken into account, and on the results of implementing Russia's own telecom projects for science and higher education.

6. INTERNATIONAL COOPERATION IN THE FIELD OF DISTANCE EDUCATION

Internet plays an increasingly crucial role in education. As we know, there are several distance education technologies based on the use of specialized satellite networks, ISDN channels and other technologies. Yet, none of these systems has a worldwide coverage comparable with the current state of Internet. Internet is best suited for internationalization of education. It is an open secret that some countries boast an excellent system of teaching a particular subject; for example, Russia has long been famous for its math schools. With Internet, our western colleagues may be given an opportunity of having Russia's leading professors teach math to them; likewise, our students could study physics at Stanford and Berkeley, etc. Because such system of worldwide education through Internet makes it possible to choose the best all countries can offer, it makes it mutually beneficial. This system should constitute yet another big stride towards realizing an open society concept. An intense daily exchange of information will make it possible to render irreversible the processes of democratization in all the countries as universal human values will be proclaimed as having priority over the ideological dogmas. To be able to solve these problems successfully, there must be a well developed Internet infrastructure in Russia and the rest of the world. Technically, Internet provides all opportunities of comfortable work, including multimedia, for such training, but in reality the low capacity of base communication channels are a major constraint. Much has been done in this area lately. In Europe and USA, projects of setting up a 34 - 45 MB infrastructure are at an advanced stage of implementation. Some segments of this infrastructure already function as part of worldwide base networks. In Russia, too, there have been some changes for the better. For example, at the close of last year, Russia's first access point of the European base network Ebone was installed at MSU. Besides, MSU is also a base point of Europe's second largest base network - 1BDNS (formerly, Europanet). As a result, in terms of capacity of international channels, MSU Internet is Russia's largest Internet provider, with channel capacity of 1.5 MBps. Maintaining these two channels calls for considerable financial inputs, but MSU and the Ministry of Science and Technical Policy, realizing the importance of promoting Internet, make appropriate financial contributions accommodating quite a few Internet clients in Russia. The fairly high for Russia level of Internet development at MSU would have been impossible without relations of partnership with the French academic Renater network and the German Institute for High Energy Physics DESY, which, in association with Russian institutions, share financial responsibility for communication channels. Regrettably, the initiative of the aforesaid organizations has so far been ignored by International institutions, such as UNESCO, European Commission, and others. Strange as it may seem, finance allocated by these organizations to support network projects in East European countries more often than not are used by Russian organizations that are not involved directly in promoting the network infrastructure. Moreover, we ourselves, on more than one occasion, have witnessed a situation where EC network project contractors use free of charge the unique (for Russia) infrastructure set up at MSU, without contributing anything to its growth. The situation is exactly the same with other Russian providers of Internet. Unfortunately, Interment calls for heavy financial investments and the only way out seems accumulation of all available resources (Russian and international) in the hands of providers on a nation-wide scale. A contribution of international institutions would be most welcome as this kind of support would expedite early involvement of Russia's leading professors in the system of world remote education.

THE PENETRATION OF NEW TECHNOLOGIES INTO DEVELOPIG COUNTRIES: CULTURAL HEGEMONY OR MUTUAL EXCHANGE

P. A. Motsoaledi
MINISTER OF EDUCATION, ARTS,
CULTURE AND SPORTS, NORTHERN PROVINCE (SOUTH AFRICA)

INTRODUCTION

The presence of a representative from the Republic of South Africa at this international congress signals the re-entry of our country into the fold of nations of the world. We are very excited and pleased to be invited to make a contribution to the deliberations of this august body. This is more so because we are from one of the poorest Provinces of our country where the legacy of apartheid has left a trail of suffering, poverty, ignorance and death.

Although we are new in the business of reconstructing a country, we are faced with a passionate expectation from our people, from the African continent and from the international community to bring into existence solutions that will remove this legacy speedily and serviceably. In doing so we are determined to employ combinations of approaches that have been used by other countries, with the careful scrutiny that ensures that the context of our country in not disregarded. The use of new information technologies is one of the measures we are keenly focusing on. Before one can delve into that, this conference needs to be appraised of the situation that prevails in South Africa after forty years of apartheid rule and three hundred years of colonial subjugation.

To illustrate that point, I will tell you about the situation of education in my country in general and in my Province in particular. It is a story of searing poverty and degradation and a story of sterling resistance and fortitude. The architects of the apartheid system had an obscene if not blasphemous strategic vision. They set out to destroy the brain, the mind and the very soul of our people. South Africa will suffer for many years to come with the legacy of "Bantu Education" - arguably one of the most successful and pernicious educational interventions and social engineering constructs of the 20th century. Its designer, H. F. Verwoerd - himself the architect of "Grande Apartheid" - stated categorically that no black person should ever be educated to a level where he or she became anything above a menial labourer. The consequences of this legislative imposition led to a concerted policy of statutory neglect of educational provision for black people on the one hand, and a progressive dismantling of all semblance of quality schooling which had existed on the other. The church schools and, in particular, the Catholic schools run by nuns and monks, fell into the latter category.

Little State provision was made to keep pace with the burgeoning numbers of black children through the. 60s, 70s and 80s. While there was some effort in the late 80s to reverse this trend, the damage had been done. Black education, even after two years of democratic rule, remains characterised by:

- *complete underprovision of resources such as classrooms, libraries, laboratory equipment, etc.;*
- *poorly-trained and underqualified teachers, tacking in motivation;*
- *the absence of Science, Mathematics and Technology, and the paralysing fear which our people experience whenever these subjects are mentioned;*
- *poor school-leaving results after 12 years of continuous schooling;*
- *poor success rates at tertiary level;*
- *complete inefficiency in expenditure of available resources.*

You might have heard about the apartheid Bantu education but you have not seen or understood it until you hear the story of the Northern Province of South Africa.

When we took power in April 1994 and I was appointed Minister, I thought that in the first five years of our new government I will be able to do away with at least the most grotesque scars of Bantu education. Two years down the line to date, I have gone only as far as to begin to understand the depth of the problems of education in my Province. It is an intricately woven bequest of oppression.

The most visible is the absence of physical facilities. The apartheid government's grand twin to Bantu education was the "Bantustans", alternatively known as the homelands. These were areas which were demarcated to be given to our people whenever they clamoured for freedom. There were ten of them and they made a total of only thirteen per cent of the whole of South Africa. The most common characteristics among them was the way they were demarcated: all of them were barren pieces of land with no means to sustain life.

Since they were to be for people who are "free" or "self governing", the apartheid regime argued that the people who live there will take charge of their own affairs, including building of schools, with their own resources. Now, when you first ensure that you put a person in a place with no resources and then turn around to say "use your own resources to build schools", what will be the result? The result will be that there wilt be no schools. The whole of South Africa is short of sixty thousand classrooms. Of these sixty thousand, thirty five thousand are needed in the Northern Province, if we are to avoid having our children attend schools in all the dilapidated structures we use.

Students were promoted from class to class regardless of their achievement, until arriving at the externally set matriculation exam - and this is where the trouble started. Failing the matriculation examination is a general norm in my Province. Last year seventy six percent of our standard tens failed. When we calculated we found that they totalled about 80,000 students. More than a quarter of all matriculates in South Africa are in the Northern Province. Among them are a significant number who have been stuck at this level up to four, five, six years or even more.

The performance of those that do obtain a pass is far below the standards required for acceptance into tertiary institutions. Since this has been going on over many years, students accumulated who had left school and who had nowhere else to go. To solve this problem, the "Bantustans" started setting up a myriad of teacher training colleges which could accept these students with poor results. They continued doing this until 1994, when the figure of teacher training colleges stood at unacceptably high levels, unacceptable even for standards of "Bantu Education" itself. These colleges have been churning out inappropriately qualified teachers who far exceed demand.

But these are not our only problems. Another legacy is maladministration. By the time we took over power, inefficiency, truancy, corruption, sloppiness and laziness had become the work ethic. In our Province this is especially significant because we have had to integrate three "Bantustans" into the new provincial government.

From time to time, countries are forced to declare disaster areas after freak phenomena like earthquakes, storms and floods, drought and epidemic outbreaks. When such declarations are made the whole country and the world are mobilised for assistance. Deputy President Thabo Mbeki visited our schools early this year. During that visit, he did the most unusual thing: he declared our Province an education disaster area. Perhaps we are the only Province in the whole world where a President of a country found it appropriate to declare an area as experiencing a disaster in education.

WHERE DOES THE USE OF TECHNOLOGY COME IN?

What I have just outlined is surely a disaster in human development. To redress this disaster, we have to be even more sophisticated than those perpetrators who conjured up this inhuman tapestry. We are fervent in our conviction that a mixture of cutting-edge technology and committed politicians, administrators and civil society will make the Northern Province an example of educational reconstruction.

There are fears and concerns and I have heard a lot of them at this very conference, too, that an unchecked introduction of technology could alienate people in underdeveloped countries from their own cultures. We want to argue that, if this happens, it will not be because of technological advances. Rather it will be because of the wrong policies adopted by politicians. Let me illustrate what I mean. In my Province there are six indigenous languages, yet only two could be shown in any form on TV, whether as news, debating programs, comedies, etc. And this, of course, did have the effect of alienating the people from their own cultures because they then regard themselves and their cultures as unimportant. But as you can see, we wish to emphasise that this was not because of the technology but rather it was a deliberate political exclusion of particular groups of people within South Africa from the benefits that modern technology can bring.

Indeed, since the demise of apartheid, the reconstruction of the South African Broadcasting System has brought these alienated communities on board. And it is interesting to note that people are now using technology to display cultures which were presumed to be long dead under colonial rule. This shows that our indigenous cultures are particularly strong, and it further suggests that, had we not been excluded from mainstream technology, our cultures might have flourished more than they do now. Indeed, we are afraid that further exclusion from the mainstream world technologies might tend to render these cultures extinct. So we believe that the important thing is to make sure that appropriate technology is introduced in an equitable manner at an appropriate pace.

For example, it is relatively easy and tempting to continually provide education of some quality in well-resourced urban environments, as was the practice under apartheid South Africa. There was more and more reluctance, however, to move into impoverished black townships and rural environments. Again, this was no fault of technology itself - technology is culturally neutral - problems arise from how technology is used by people. It is essential that any technology programme focuses on these intransigent education problems rather than simply expand the elite.

In my Province there are several main thrusts we are concentrating on:

- the shift of paradigms towards a more learner-centred instructional methodology and re-orienting our education system away from the apartheid "Bantu Education";
- improving the quality of our teachers;
- bringing the teaching and learning of Mathematics, Science and Technology to the forefront of the whole education process;
- modernising management systems and reshaping

our human resources to be in line with advanced and scientific approaches;

- improving material resources and facilities in the entire system.

In all these thrusts the strategy will be to rely heavily on the employment of New Information Technologies (NITs). This is especially urgent as it is becoming more and more apparent that the present educators can no longer cope with the increasing volume of people, children and adults alike, whom we would like to educate. And this situation is most urgent in the rural areas, and specifically in my Province where the human resources development index is the lowest in the country - we have to rely on technology to enhance the effectiveness of the relatively small pool of educators.

TEACHER EDUCATION

At the beginning of this year, we took a radical step and discontinued first year intake into two thirds of our colleges of education. Our intention is to gradually turn these rationalised institutions into technical schools, technicons and other facilities which can produce resources needed by the economy. The unemployment figure in my Province is the highest in the country, at 47 %. Already in ten of these colleges, we are running a mathematics and science bridging programme which is aimed at assisting students who have passed standard ten but whose performance falls below what is required in tertiary institutions or technical employment. Through the extensive use of technology, these students will be leapfrogged into the modem world.

Apartheid education made an all-out effort to ensure that the black population is kept as far away from science and technology as possible. This is in keeping with the Verwoerd statement in Parliament in 1953 during the debate on "Bantu Education" that "there is no need to teach a "Bantu" child Science and Mathematics, because the government will not allow him or her to use it".

We see it as our duty to reverse this destructive policy which in the past forty years has proved to be extremely successful. To this end, we have developed the concept of a Mathematics, Science and Technology Education College (MASTEC) whose aim is to improve the quality of education in these fields and to foster an atmosphere of excellence. This college will be dedicated to the production of Maths, Science and Technology teachers of a high quality. MASTEC will pioneer an innovative approach to teacher training where teacher trainees will be taught in the way we want them to teach their students. Pedagogy and subject content acquisition will be highly integrated; school experience will start in the first year of the student teachers' training and go through all four years. They will work on projects designed to provide hands-on experiences that can form the basis of their own learning, and inform the way they will conduct their classes. Co-operative group work and brain-storming class discussions will provide these teacher trainees with the opportunity to master the language of science and acquire science process skills.

And all this will take place in a computer rich environment, where technology such as Microcomputer-Based Laboratories will enhance the acquisition of physics concepts, and where productivity tools such as word processors, spreadsheets, and data base software will bring students into the 21st century.

EDUCATION MANAGEMENT

To create an effective decision support system, it will be necessary to integrate data from different racial and tribal groups which were held in disparate databases in keeping with the then official policy of segregation. Not only is there the problem of technical incompatibility but also political extremism among officials in charge of these databases, who owed allegiance to the old regime. Since data leads to empowering information, it is not surprising that this gave rise to gatekeepers of all sorts - a clear example of how technological dependence could lead to the worst form of oppression.

The approach we are adopting, under the auspices of the Independent Development Trust (IDT) - the largest NGO in the country, is to develop what we are calling an Education Management Information System (EMIS) that meets the basic requirements of a computer data processing system. This entails the gathering of inputs, processing them, and producing outputs. In addition, those who had historically been excluded from the process of information gathering and evaluation will be slowly empowered to become information workers in their own right. Another obvious improvement is the time taken before the processed results are available. Previously, this was 12-18 months - with this new approach, it will take a maximum of one month. For people who take technology for granted, this might not mean very much. But for my people in the rural Province this represents a great revolution in both cultural and economic terms.

Previously a newly employed teacher could wait up to six months before getting his or her first paycheque! In fact, I must confess that when I was young, I thought this was a natural phenomenon, because I was born into a family of teachers for whom this was a normal feature of life. Imagine what excitement will be created when people get their paycheques on time.

The main elements for implementing this approach would be:

- training the lower level management in the Education Ministry to be computer literate;
- installing computers in all the remote offices and networking these with simple dial-up telephone lines;
- developing software to support this distributed model of computing (shifting from centralised mainframes to distributed PCs);
- producing sophisticated Decision Support Systems for all levels of educational management.

To achieve these objectives, it is obvious that massive resources will be required. The IDT and REACH and TEACH (another prominent NGO), in partnership with my Province, have set about developing a framework for co-operation to achieve these goals.

REACH AND TEACH has been tasked with the infrastructure aspects of this assignment - the installation of computers at deep rural circuit and area offices, as well as supplying the training of basic computer literacy. This has involved some novel approaches, since many areas do not have electricity. The use of solar panels for this purpose has been tested and found to work effectively. In areas where no telephone communications exist, the option of using either satellite or high-frequency radio telephones is being investigated. In this way, we will reverse the marginalisation experienced by these communities.

The consultants from IDT have been tasked with developing the software to split the workload of capturing and assimilating the data between the remote sites and the head office. The first phase of this development will be a system to complete the "Annual Return of Schools" data at the remote (circuit) offices.

With a sophisticated communications network in place, a steady two-way stream of information can be maintained. This would be particularly useful for future requirements for tighter control of school provisioning, textbook deliveries at remote offices, etc. Again for people who take technology for granted, this might hot seem very important, but gross inefficiency brought about by lack of information on, for instance, how many textbooks are needed, will make this particular change seem like another revolution to the education department in my Province.

A government committee to oversee the implementation of EMIS has been established. The installation of computers at the various offices is ongoing, networked with modem access and e-mail. A training programme is being finalised and many officials will receive such training before the end of August 1996. During late August or early September 1996, the entire Province will be involved with a data capture exercise to record all the schools enrolment data.

It is the intention of my Ministry that the means to address the most marginalised of communities must be the most modern technology. Thus in a rural area like the Northern Province we will be using computers with solar panelling and in the near future satellite links for communication. What appears on the surface to be almost anomalous, we intend to make the norm.

COMPUTERS IN THE CLASSROOM

The consistent use of technology throughout the administration will make it much easier to introduce computers into classrooms. In so doing, it also becomes possible to use the technology to change the existing approach and apply a more learner-centred instruction methodology in a resource-based learning environment. Seymour Papert, in a recent book called "The Children's Machine", writes about the intransigence of educational systems to change. He indicates that the school operating today does so in very much the same way as it did some fifty years ago and this, in spite of the tremendous amount of technological innovation that has taken place.

There are a number of well-established principles for reforming education that are known internationally. These include the following:

1. Changes need to be both top-down and bottom-up. This implies that both the bureaucracy which manages education and the school itself need to be involved in any kind of reform agenda. The time is clearly ripe in South Africa for something of this nature to happen given the fact that we are one of the few countries in the world where a total restructuring of the educational bureaucracy is at present underway while, at the same time, there is tremendous disaffection at grassroots level with the quality of education delivered by the schools.

2. It is essential to view school as the entity for reform. This implies that:
   - there must be proper structures for governance which create community involvement with the school;
   - all parts of the school need to be involved in the reform. This is not something that is for teachers or for children only, but is something in which the entire school from the principal through to the pupils need to be involved in and share. This implies also a mutually shared vision for the school.

3. It is essential to create a learning environment that supports effective teaching and learning. This in its turn implies:
   - a programme of training principals and their deputies in the principles of school management, as well as equipping them to support the educational changes being introduced;
   - the creation of a resource-based learning environment so that the teacher is not the only resource available but that small group interactions become an integral part of the learning environment within the classroom;
   - within this environment it is essential to integrate technology and, in particular, computers and multimedia to support learning.

To actualise a programme of this nature it is essential to establish an infrastructure which can support it. The essence of the programme in the Northern Province is to establish Educational Resource Centres (ERCs) which can serve as the engine driving the education reconstruction process. It is envisaged that these centres will be not only the administrative home of the programme but also places at which high-tech equipment such as computers and other multimedia can be placed. The ERCs will be used to train teachers throughout the Province in the use of this methodology which, at the same time, will enable them to become computer-literate. Each ERC will thus form a hub of education activity for the schools surrounding it.

Finally, a major problem which has confronted the Northern Province is the one mentioned above about students who are repeating their school-leaving examination at standard-ten level many times. At the end of 1995, the Ministry took decisive action to remove many of these students from the former schooling system. This was essential to prevent them from clogging up the system and serving a blockage to further education reforms within the schools. All these students were offered the opportunity of what has now come to be called "Finishing Schools", which presently house some 30,000 pupils. Clearly, if they are taught in the same way as was the case in the past, then their success rate will again be minimal. So. together with the IDT and REACH and TEACH, the Ministry is planning to mount a programme to use technology within some of these finishing classrooms to help those in particular attempting to pass Physical Sciences, Biology and Mathematics, in particular.

In conclusion, I trust that you now have gathered some insight into the problems we are confronted with in my country in general and in the Province in particular, and our plans for using the new information technologies to address these problems. I hope that next time when we meet, I will be able to declare that education in my Province is no longer a disaster area -this can only be achieved with the support and help from all who attach importance to nurturing the new democracy which South Africa is today.

I hope I have made it clear that you will agree that the penetration of technology in developing countries may not be a cultural hegemony. In fact, we are having discussions with representatives from various countries who wish to connect schools in their countries with schools in my Province, so that Russian, American, South African, and students elsewhere can learn from each other, thus forming the nucleus of a mutual cultural exchange.

The original is presented in English

NEW INFORMATION TECHNOLOGIES AS A CHALLENGE FOR GENERAL EDUCATION AND VOCATIONAL TRAINING: CHANCES FOR INTERNATIONAL CO-OPERATION FROM THE POINT OF VIEW OF THE FEDERAL REPUBLIC OF GERMANY

Heinz-Werner Poelchau

MINISTERIAL COUNSELLOR, CHAIRMAN OF COMMISSION OF EDUCATIONAL BROADCASTING
MINISTRY OF SCHOOLS AND ADVANCED EDUCATION
OF THE REGION OF NORTH RHINE -WESTFALIA (GERMANY)

I thank the organisers of this Second International Congress on Education and Informatics for the opportunity of introducing and making a few general comments about today's topic of discussion - Social, Economic and Cultural Issues.

Obviously these come from the point of view of a representative of an industrialised nation. This means there is a risk that various viewpoints which representatives of other countries will undoubtedly wish to be considered cannot be addressed by myself. Therefore I ask this to borne in mind. I will nevertheless try not to place too much emphasis on the narrow German viewpoint, but will instead discuss a few questions about the international situation and draw some conclusions from my perspective.

It seems to me to be appropriate for the topic to be placed in a wider context followed by a discussion of concrete action undertaken in the Federal Republic of Germany. I will conclude by repeating the question of which policies UNESCO offers its members, that is to say which forms of reciprocal exchange in which areas would be of most interest to all.

About ten years ago a director of the IBM company compared the developments in the area of new Information Technology like this: The flow of information from America to Europe a few years ago was like sending a Jumbo Jet at 500 miles per hour over the Atlantic. Now one could send the same amount of information at many times the speed of sound in a mode of transport the size of a fly. If one wished to continue this development then today's form of transport would be barely seen under the microscope and its speed would come close to the speed of light.

This picture of increasing rates of development is closely connected with the growth of knowledge in our world. More than half of all the scientists that ever lived, are living today and the length of time that their scientific developments are valid - or indeed go out of date, and are overtaken - has been reduced to a timespan of between three to five years.

Yet on the other hand the ability for Man to come to terms with and understand this new knowledge has practically not changed. I know of no medical work that shows Man's brain has got noticeably bigger or that the speed of its comprehension has increased. And sadly one must also take into account that there have never been so many wars in the world as since World War Two, that daily, people die from hunger on this Earth and that damage to the environment has never before been witnessed on such a scale.

The challenges for politics and in particular for the politics of education, which follow from this many-faceted development in technology on the one hand and society on the other, are therefore to be answered comprehensively.

In doing so, it is important for me for the focus of my discussion not to dwell on technological problems and possibilities but rather on the needs of society and to ask whether this new technology can provide solutions and if so in which ways. Obviously it is not possible here to discuss all the problems of the world, but only those which can be solved with the help of these new technologies.

Peace, freedom, social equality and personal well-being are without doubt some of the ideal principles which all peoples and all nations strive for.

Important foundations for the fulfilment of these aims are understanding between peoples, the safeguarding of nutritional resources, the development of well-being, the economic prosperity of nations and the potential for the individual to develop him or herself.

Much effort has already been put into all these areas; the striven for development and intensification and consolidation of this work is, and remains, the central task for shaping our future.

Here the information and communication technology can and must perform a central role, if it is not only to be viewed economically or technologically.

It seems clear that the NITs can perform the task of teaching knowledge and understanding very well, because they can carry information and opinions world-wide, quickly and efficiently. However the Main Document of this conference points out that this technology and the information it carries is a product of western thought. Hence the contents of this information does not necessarily correspond to the traditions of thought and the cultural heritage of different nations, not to mention the fact that most of the content is in the English language.

Therefore it can have a negative influence on the conservation of each nation's culture. New problems in mutual understanding can occur due to the direct confrontation between different cultures which without this technology would not have had happened.

The overall dominance of American, Brazilian, Australian or Japanese films and video games which determine the world market have brought forth not only positive reactions. More significant for example is the introduction of a quota of European material in the European TV schedule in an effort to protect European heritage from the American competition.

However in Europe there is not yet licensing for software. The production of many software products from Japan and the USA shows however that even in the area of digital technology one can see influences on cultural tradition. A not inconsiderable influence can be expected on the educational process due to the fact that these products (especially computer games) are aimed in most cases at children and young adults. Through this new divisions could be created between cultures which would work against the possibility of mutual understanding.

If this is already a problem between developed countries then it can be expected that especially between developed and developing countries an even bigger divide threatens. To prevent new cases of conflict close co-operation between countries is of special importance. New technology can be again useful in this quest: new technological possibilities between cooperating parties can widen and intensify this co-operation. This can be achieved without the problems of long, costly teamwork; sometimes impossible journeys or even complicated production techniques.

Inadequate social conditions in the different countries give countries a great challenge - within and between themselves. The gap between rich and poor in many cases does not seem to be getting smaller and is even increasing in parts. The reduction in these inequalities must be in the interests of all states and all governments.

In addition considerable to these economically-oriented disparities are new disparities which can be best described as the gap between the information rich and the information poor. Due to lack of financial resources and insufficient training new information technologies cannot be used in the most efficient way. This divide appears more and more not to be a problem as much between developed and developing nations but more within the country itself with its attendant difficulties.

Less developed regions within developed countries have similar problems as exist between developing and developed countries: a reduced participation in the development of society, reduced income growth or even setbacks in overall development for example high unemployment etc.

The new information and communication technology maintains existing imbalances and strengthens these. Of course the possibility exists that this technology, if an opportunity of equal access existed, can eliminate these imbalances. Where previously information technology was open to a few it is now available to many who allow themselves to work with independent strategies and beliefs and enter competition of a new structure.

Nevertheless this requires making this available for all and that the necessary skills are provided. This again requires the improvement of general training which need to be developed further.

This new technology is as much a challenge as it is a possible way of overcoming social disparities. They connect nations in previously little known ways for the task of preventing the gap between the information rich and the information poor becoming greater with the subsequent consequences. New co-operation possibilities are presented which though they come from different sides can lead to a mutual goal.

The welfare of the individual is greatly dependent on his or her health and income. Income is necessary for the purchasing of food and other important products. Health is dependent on sufficient food and the provision of these other products necessary for life, health is required for the individual to earn an income through his or her own labour.

Though new technology can make the production of these products necessary for life easier, and can sometimes optimise it, its implementation is dependent on sufficient resources being available to gain this new technology.

New technology can contribute to the development of medical care and treatment, it can make necessary information for diagnosis and therapy ready and available on a wide scale. Again there is a requirement that sufficient financial resources are made available to purchase this technology and to train its users so that information is relevant and useful. For example constant data access on the internet is only of use to those who understand how to deal with this information. Another example are satellite television courses about new treatment procedures which are only available to those who have satellite dishes.

The possible role for this new technology in solving these aforementioned problems of health care and availability of food and other important products can be assessed thus: it is dependent that sufficient financial and training resources are available.

This new technology has obvious connections with economics. The development of economies is brought about through the constant adaptation to changing requirements of national and international kind. New products, new methods, new trading partners are important vehicles for development which leads to new jobs and new income.

In this area new technology has led to revolutionary changes in the past years, or at least has contributed to them coming about. The positions of entire industries have changed due to the new possibilities for development which have been realised - changes to products and their production, as well as new markets and marketing strategies. The new technology has itself been the vehicle for change and have had a significant impact on other technology.

In the Federal Republic of Germany one estimates that in recent times there has been a 50 per cent increase in the number of jobs in the information processing sector. This information sector is itself a significant market area and production and marketing is economically important.

In my region of North Rhine Westfalia with its well known Ruhr area, the European centre of coal and steel, the number of those employed in the media sector has recently become twice as many as that in mining sector and comes close to the figure of those involved in the steel industry. Companies like Mannesmann have built up large telecommunication enterprises and more will follow.

The change from industrial society to an information society is in full swing and requires a greater effort from all those involved.

Nevertheless many challenges are connected with this which need to be mentioned: changes in work organisation, the decline in qualifications, and the necessity to offer new types of qualifications to the many young adults of today, unemployment, increasing expectations of quality in work and in the product, increasing competition etc.

From the above it can be shown that this new information and communication technology has had many consequences on general development in the social sphere. Therefore a discussion of the effects that this technology has is too brief if one concentrates on isolated economic or social areas.

For it is to be assumed that the increased use of this technology will lead to changes in economic and social structures, and one can already see roughly this development taking place. For now the question of further developments in social security systems interest us, in addition to the questions about the future workplace, the question about the soda! contribution, the question about economic competition potential and the question of new training possibilities as well as the future of the new organisational structures in government and business.

A number of experts on all levels are working on papers, imagining new scenarios and possible lines of development. They are suggesting consequences of further political action and are giving encouragement to the various institutions.

These groundbreaking actions and their subsequent effects are not only tasks for national organisations and businesses but are to a greater extent challenges which extend over national boundaries and are being faced by the European Union, having been given highest priority.

The great consequences of this technology and subsequent strategies has a clear impact in the education sphere: a concentration on one subject or area is just as pointless as restrictions regarding age or even entrance to vocational training.

If one wishes to assess the possibilities and problems of NITs then this can only be possible if many differing aspects in all their variety are borne in mind and are considered. At the same time this means not only a concentration on making this technology available but also on comprehensive understanding of its possibilities and problems.

Therefore we already had begun in Germany in the mid 1980s to give pupils in secondary level 1 a basic qualification in information and communication technology. At the same time it was ensured that in other subjects pupils could experience the different practical uses of the new technology in their projects.

Using concrete exercises such as the production of a school newspaper allow pupils to experience the possibilities of word processing as well as allowing them to identify and discuss the problem of copyright. Using the model of a survey on a subject of school life allow the opportunity of using tables and calculations and presenting these in a graphical form. In addition to the object of this teaching, the question of data security and its misuse should be addressed. Through the use of CAD and CAM programmes real products can be created but other issues must also be considered such as the impact on employment, the agreement of management and other questions regarding the workplace.

In later school life there is an opportunity for the pupil to widen and deepen the basic knowledge gained - in the compulsory optional section of secondary level one and in the subject of information studies in secondary level two. Since a few months ago, under the title of *'Schulen ans Netz'* ('Schools to the net'), we have been giving schools in Germany the opportunity to test new forms of preparation and teaching of lessons via the internet. Large German and international firms as well as state governments have offered their help in this. Within three years we wish to build up and firmly establish these numerous opportunities in the schools.

In past years the attitudes to this new technology have changed so that increasingly the whole technology and not separate pieces have found their way into the classroom. That the skills and the technologies which go along with them. has grown together through digitalisation confirms the views. This is an overview of the introduction which has shown how this technology can be used and transmitted and how this is more important than individual pieces of technology. In this way the contents of information have grown, especially with the growth of new telecommunication possibilities such as the internet, which connect them together to form a new competence - the media competence.

Parallel developments have occurred in vocational training. A few years ago definite skills were demanded which young people could use in daily work. Now the new skills demanded can be better described as key qualifications. These skills are available and can be strengthened in general education as well as in specialised training. General skills such as organisational and planning skills, communication and co-operation willingness, mastery of thinking and learning strategies, independence and willingness to assume responsibility as well as responsibility in different situations.

This comes about due to the ever-changing challenges which are placed on the individual in modern working life. One must react flexibly to these challenges especially as vocational knowledge goes out of date rapidly. The aforementioned key qualifications are the requirements for the constant adaptation to the challenges, this has been shown for example through the new structure of vocational training for metal and electrical trades. Several hundred training programmes were brought together and general requirements were established. Only then did specialisation occur, specialist knowledge being defined and teaching contents set out.

The aforementioned key qualifications show clearly that the previous division between the role of general and vocational training has become increasingly flexible. There is now little difference between the basic qualification requirements. Thus one can understand the view that for those seeking employment vocational qualifications have the same weight and quality as those of a general nature.

However this means also that topics must be considered in the vocational field which although of equal importance are nonetheless different. It is of importance, just as in field of more general education, that the orientation of future discussion for young people when addressing and solving general problems concerning projects, must be on the end product.

To make this clear I will give five examples which illustrate the aforementioned discussion and conclusion.

In a number of vocational schools in Germany a series of projects were completed between 1992 and 1995 under the title of *'Integration neuer Technologien in den Unterricht berufsbildener Schulen und Kollegschulen unter besonderer Berücksichtigung der Leitidee der sozial- und umweltvertraeglichen Gestaltung von Arbeit und Technik'* ('Integration of new technologies in the vocational schools considering the leading idea that labour and techniques should be adequately adapted to social and environmental aims'). It did not concern itself overtly with the provision of new technology but instead dealt with the modern technology as a tool and in comparison to the lessons of the vocational schools.

In the first project production economy was discussed, that is to say production, storage, transport as well as the sale of goods in the face of competition - but also with the background of raw material shortages and environmental pressure.

Nowadays such production economy systems can only be achieved using modern technology, in every case expenditure is calculated with this technology, prices and delivery times are calculated, transport tasks are given and production and its requirements are defined. In most cases this expenditure occurs with the needs of the individual company in mind, never - or seldom - are such decisions made when economic or manpower problems threaten.

With the help of scenario-techniques and mind-mapping, pupils worked on alternatives for an environmentally friendly production economy system. They also discussed the new challenges which would face the employees of this new system. For example it was worked out that although scanner-tills were an efficient way of ensuring fresh deliveries, that at the same time it was not possible for the till operator to have an overview on daily income and on the economic position of the company. Their task and their wish to witness their companies success through their own work thus becomes difficult. There exists the danger too that their motivation to work will suffer due to their lack of this overview.

The goals of these lessons were to understand simultaneously the different types of new technology and in equal measure their effects on the individual and on society.

In a second project of the same series the young people were asked to redesign their teaching room and to give directions and planning as concerned building and equipping the room. Software programmes available to all helped in drawing of plans and the necessary text. Thus work, educational and economical questions were central, the new technology had an instrumental character. They helped in calculating and presenting work results in a most convincing manner.

Beside vocational skills which are required for the construction of a work bench, drill or other tool, there communication and co-operation willingness stand as important key qualifications in the centre of teaching. Of course a reflection of the possibilities of the new technology was needed to solve this task. Thus it shows that available software was suitable to begin to work out solutions independently and that it is difficult to develop vocational knowledge and computer skills at a similar rate.

In a third project in northern Germany these similar self teaching possibilities were tested with the help of new media of technology. In a teaching centre the pupils of a vocational training school had the opportunity of extending their knowledge of the available resources through independent research and analysis. Different technology and information were available in a room of its own. Teaching programmes and courses using PCs allowed pupils to practice skills and allowed them also to research databases.

Of interest is that this teaching centre was not only available to the pupils of the school but also to interested parties outside the school. Thus a bridge could be built between academic training and further training available outside the school. The teacher in this teaching centre clearly had other tasks from the classroom teacher. He or she is no longer the source of knowledge but rather the trainer or coach of those who wish to work independently.

From past experience it has been shown that not only a narrow range of databases and materials must be made available to those in self-learning who are working on a specific task such as a metal work product. Business help must also be available, for example dictionaries when preparations are made for the manufacturing and sale of products abroad, if teaching success is to be achieved.

Such connections are required if one is to remain faithful to the goal of vocational training - a training which gives general key qualifications.

In addition to these key qualifications belongs the preparation for a life long learning. To learn to learn is one of the most important qualifications of the future because even as an adult one is required to gain new knowledge independently. Not only the many opportunities of vocational and general education, which are offered by chambers of industry and commerce and vocational schools, serve this goal but also the teaching programmes which industry develops and offers its students.

A very recent example is the PC aided self learn programme of the SIEMENS company which was developed in partnership with the German ministry of education and science, research and technology. *'Lernen in der betrieblichen Praxis'* ('Learning and working in practice') is a course which can be studied independently by trainees and the basic skills of the learning processes can be utilised on the job.

This programme is entirely on CD-ROM and allows the development of basic skills in each of the formative vocational trainings. It is interesting to note that not only can specific knowledge be offered but a certificate is awarded after the successful completion of training. The computer itself checks if the trainee has acquired all the necessary knowledge and then produces a certificate on the result of the training.

A final example shows the numerous uses of NITs in the acquisition of knowledge and skills for the adult.

Since more than twenty five years the public broadcasting, vocational schools, colleges and the ministry of education have been working together to give adults a second chance to reach a higher level school exam. The school qualifications available in the Telekolleg is recognised by the state authorities for entrance to a higher education course of study. Broadcasting stations beam out daily several educational programmes regarding various school subjects. The students work independently with corresponding written material and since recently with software which allows them to practice. Approximately every two weeks there is an extended tutorial at the educational establishment where remaining questions can be addressed and discussed. Internet connections between the students give the opportunity to discuss open questions. During the two year course exams are taken step by step in a total of thirteen different general and vocational subjects. Thus finally a qualification is awarded. The new technology are offered in and in addition to the vocational training.

In total fifty thousand people have repeated their end of school qualifications in such a way and can now undertake study. Today those who have finished Telekolleg became teachers and now teach the new students.

These examples of the utilisation of new technology show clearly that in Germany there already is comprehensive experience of their use in general and vocational education. Hence I would like to suggest a few possibilities for working together on an international scale.

It seems to me to be important to make mention of the reciprocal exchange of information and resources. This can be done electronically or using the more traditional method of documents and papers. In doing so one must ensure that these resources are not only of use to one culture but must be adapted to the needs and circumstances of partner countries. So real fresh partnerships can be established. Because this new technology is an area of international competition a danger exists that not all information will be made available. This appears to me to be particularly inappropriate and unfair in the area of education. Especially those countries which are still in the development stage require comprehensive support to be able to master their problems in the future. Industrial nations are called upon, within their capabilities, to provide this wide ranging help.

A dear setting of targets and realisation of the problems heightens the possibility of mutual exchange of ideas and can lead to countries working together.

Besides exchange of information about programmes the exchange of people with their experience is of utmost importance. In the framework of existing cultural and economic agreement between nations all possibilities should be grasped and used effectively, thus supporting, through contact between people, the exchange of experiences. In addition bilateral and multilateral meetings are possible and sensible. They should take place on a regular basis and should rely on existing structures. Congresses and conferences and their accompanying exhibitions are especially important because here the education and business partners can discuss areas of mutual interest.

Such actions seem particularly fruitful when joint training is planned and put into action. On a European scale the programmes of the EU have already borne fruit. They should be encouraged to be implemented by other multilateral communities. We in Germany have had very good experiences in working together with the Pacific area and are willing to widen this to other countries and establish new contacts. Joint projects organised from government as well as joint actions from non-governmental organisations are of great importance. Especially in the area of vocational training contacts between companies from different countries are possible. I am willing to be of assistance in this aim.

We have in Germany a series of institutions which develop multimedia products for vocational training. They also have multimedia products which could be of great interest to other countries. I would be happy to see other countries benefiting from this experience. Business exchanges as well as assistance in making and using the products can be initiated. At one of the institutions in our country educational software in German is tested. From more than four thousand tested programmes, which are offered to the German market, less than eighty could be suitably utilised. I am willing to make known our criticisms and results and thus give an impetus for the improvement of these products.

It seems to be necessary, due to easier means of international communication via the Internet, that international forums be set up to deal with the experiences of this new technology. I would be happy if it were possible to create such a forum not only on the level of individual institutions and training programmes but instead to begin discussions on the level of responsible co-ordination of this co-operation. I would thus welcome a move from UNESCO in this direction.

Nevertheless it is important to make available the material resources for a wider uptake of this new technology. The governments are asked to overcome barriers with their strength. It would be scarcely thinkable however that these great challenges are given solely to governments. I am convinced that it is in the interests of national and international organisations and companies to create possibilities, in a public-private partnership, so that conditions can exist for the peoples of various countries to play a part in improved development. Other international organisations and the availability of finance can contribute through encouragement and programmes so that new possibilities for development can be created.

Ladies and Gentlemen, I thank you for your attention and I am most willing to discuss further details with you afterwards.

Commission I

HUMANITARIAN EDUCATION ON THE EDGE OF 20 th - 21 th CENTURIES IN A NEW INFORMATION ENVIRONMENT

Yu.N. Afanasyev

RECTOR, RUSSIAN STATE UNIVERSITY FOR THE HUMANITIES

1.EDUCATION INFORMATIZATION AS A GLOBAL PROBLEM ON THE EDGE OF CENTURIES

The edge of centuries in the history of humankind has repeatedly been associated with global change in the understanding of the world: reformation on the edge of the 16 th -17 th centuries, Renaissance on the edge of the 18 th - 19 th centuries, search for the methods for the management of matter and natural forces on the edge of the 19 th - 20 th centuries. Before our epoch science was concerned with multiplication and accumulation of knowledge, whereas today it essentially focuses on the methods for mastering of the accumulated knowledge and has recognized the global role of informatics in its further development.

In addition to the mystic expectations common for such a chronological period and prophecies, the 20 th century brought quite realistic and explainable problems and crises, both global and local. Among the global problems, the most serious appears to be the issue of education as a whole. Its ideals and goals, the content, the method and technology appear to lose the usual stability, and occasionally they lose polarity. The humanitarian education is an inseparable part of education as such, and these painful vibration are quite specific for it. But - «where there is danger, there is saving».

My understanding is that the most essential thing today is to provide an adequate insight into the nature of knowledge, which has drastically changed over the last decades. Without that we could hardly define coherently the place and the role of new technologies in the humanitarian education. It appears to me that we should take into account the fact that computerization of a humanities school, i.e., filling of the educational space with computers and its informatization, i.e., a drastic increase in information resources and respective technologies are not the external factors of the education process. These processes are the least likely what is called aids to teaching humanities. This is a completely new information environment - a new dynamic form of knowledge per se, and, concurrently, a new form of humanitarian education, the form obliterating distinctions between scientific research) and study knowledge, or fundamental and applied knowledge. A rapprochement of humanities and natural science knowledge is under way, and the artificiality and conventionality of the disciplinary structure of both study and scientific knowledge becomes evident. In the new information environment, knowledge is a single dynamic system, alias «living knowledge».

Surprisingly, the new information environment fully meets the most essential needs of humanities education. It not only permits avoiding the mass and average nature of education - this merely becomes impossible - the new information environment in the humanities institution can only be used to the full individually.

This is in a way «submergence» into the system of integral knowledge and it personal experience. Understandably, being creative this submergence calls for thorough and abundant preparation.

This understanding of knowledge makes it possible for us to speak in terms of a principally new concept of humanitarian education.

2. THE PLACE OF RUSSIAN IN THE DEVELOPMENT OF INFORMATION TECHNOLOGIES

Such a representative form as the UNESCO Congress on the relationship between informatics and education is held in Russia, and I shall discuss, if only briefly, the Russian situation in information technologies.

There are three points of common knowledge:

• There have always been excellent programmers in Russia.

• The standards of Russian-made computers have always been very low (Russian-made computers are practically non-existent).

• During the recent years, the computer market in Russia has sharply increased from zero, and the number of computers being sold has considerably increased accordingly. With respect to this index, Russian approaches the European leaders. How can this situation be commented on? On the one hand, we appear to be doing well. However, I am not optimistic with respect to further prospects. Firstly, if Russia claims to be a great power, it would not exist on imported equipment, no matter how good, for a long time.

We need high technologies in terms of the creation and production of the entire computer complex. Secondly, the relationship between the level of programming and its logistic support is by far more complicated than the more computers - the higher education level postulate. True enough, the economic and research and technological policy in computer sphere is not my specialty.

Thus, we see a sharp growth of computer sales in Russia. But the software products are sold to a by far less extent - alas, it is used illegally, to put it mildly. But despite that, and also despite the fact that the majority of the computer equipment sold in Russia are of «yellow» or unknown assembly, this is an undoubted advantage. Although nobody can say *what and where* all these computers are engaged in. What I have in mind is not a census, but rather lack of ides as to the actual informatization of the most essential aspects of social activities. My suspicion is that the bulk of the computer fleet of Russia comprises game machines, typewriters, or occasionally, a fashionable element of the office design. Perhaps, this is natural in our conditions - massive informatization in Russia has just started and they need to get used to it.

But on the other hand, the very possibility of retaining the level of computer equipment sales in Russia is dubious. The initial needs have been met, and further movement is only possible due to the distribution of computers among individual users. And, are there many personal computers in Russian apartments? Is it a purely economic problem? Of course, not.

I shall dare say that computer culture in Russia is so far low, and new information technologies are subconsciously rejected. The reason for that is a separate exciting topic. But for those of us who are associated with humanitarian education in Russia, our objective is self-evident. We are to cultivate this computer culture and to patiently demonstrate what can be accomplished through information technologies, and how they can bring us to a new intellectual level, and how it will expand our personal liberty and personal creative potential.

3. ON HUMANITARIAN EDUCATION PROPER

Understandably, even the most essential issues of humanitarian education cannot be merely listed, hence, I would like to dwell upon those that I am most concerned with.

Reflecting on humanitarian education, its present state and, particularly, of its future, I come to the conclusion that the problem of education is secondary. The primary problem is: what will a specialist in humanities be like tomorrow (thanks God, we gradually reject the «what should be like» modality). What can we envisage? And, what we cannot imagine even in principle?

To be quite frank, when I meet five-six-graders of today I can hardly fancy them becoming specialists in humanities in 10 - 12 years. But my professional and civil duty require my making decisions that would concern them as early as today. True enough, it is impossible and unnecessary to change many of the things in humanitarian education: the general structure of specialties, the traditions of the leading research and educational schools, efficient technologies...But along with that it is evident that schoolchildren of today will live in an essentially different world, which, I am afraid, will be no less dramatic and cruel.

The need for humanitarian culture will increase. To retain and, all the more so, develop humanitarian culture is only possible for free creative people. Of course, they can live and work *only in a democratic society.* But this is not enough - in addition to certain political conditions, they will need professional creative freedom. Respectful of any authorities, they will not be dependent on them. And, the most important independence is *informational.* By gaining access to modern data bases, the future specialist in humanities would be able to build *his own* information space, develop his original concepts and models of the phenomena and processes studied. The information freedom is thus a condition and, concurrently, a form of political and creative freedom. *Providing that freedom is exactly the point of informatization of humanitarian education.*

But not everything is that simple. Liberating oneself from the dependence on the «classic» authorities, the future specialist in humanities risks becoming dependent on developers of data bases, software products and merely on computers with their queer attractiveness.

There does not seem to be any other way to avoid this danger other than to *teach a humanitarian to develop data bases and critically assess the available programs on his own. He may not be able to develop programs on his own but he should be able to select the most suitable ones.* In other words, he must master this form of culture. And, for the humanitarian education as a whole, the goal is adequate rationalization of the humanitarian knowledge, assimilation of the available knowledge and development of new methods for stricter tackling the available knowledge. That is why the problem of informatization in humanitarian education becomes dominant, including the selection of developmental strategies of humanitarian education as a whole as:

- incorporation of humanitarian schools into modern information networks;
- development and mastery of new information technologies in education;
- rapprochement of research and study process on the basis of new information technologies.

I think that development of the tools for humanitarian sciences using modern methods for work with information is quite humanitarian, deserving a profound and unhurried discussion. This problem is multi-faceted. This comprises development of information data bases, statistical analysis, graphic representation of information and many other things. But presumably the main and the most difficult problem will be the one of the application of mathematics, mathematical models and the application of the method of models with the traditional instruments of humanitarian sciences.

It is exactly now that new possibilities and new ideas of the use of mathematics, the ideas of the unity of formal methods created by mathematics with the technology of analysis traditional for the humanitarian sciences originate . And, very importantly, that these ideas acquire the necessary hardware and software support. They open up the prospects of this symbiosis.

Still another issue is noteworthy. Are we often concerned with the social role of a specialist in humanities? He is to keep and multiply humanitarian knowledge, humanitarian culture. But is he to do it for himself only or is he to enter in contact with other forms of culture, is he to fight those who endanger culture *per se*. And, if he is to struggle then in what way?

I don't think anyone would seriously doubt that excessive scientization and technization, in other words, hyperbolized rationalization of our life is hazardous to the very existence of humankind, the roots of this excessiveness, alas, lie in the system of natural scientific and engineering and technological education. The most acute social problem *humanization and humanitarization of this system of education* has long become self-evident. It is also self-evident that *this problem is beyond natural scientists and engineers alone.* But a mechanical introduction of humanitarian disciplines in such schools is hardly productive as shown by experience. The problem is stated but is not being solved.

A sort of «internal» humanization and humanitarization of natural and scientific and engineering and technological education is necessary. The most responsible goal of humanitarian education is the reform or saving of another part of education. To some degree it is a problem of self-saving for humanitarians.

From this point of view of great interest is a system of study courses on the history of science as technology as a natural humanitarian basis of professional scientific and technological education. In the Russian State University for the Humanities we are now attempting to develop such a basis, using the most sophisticated information technologies.

4. EDUCATION AND INFORMATIZATION IN THE RUSSIAN STATE HUMANITARIAN UNIVERSITY

I wish to briefly discuss the Russian State University for the Humanities project. Not only because this University is close and deer to me - I could show concretely what we are doing, what are our plans and problems.

As you know, Russia is now passing through the complicated transition period with great difficulty. The entire system of Russian education is now having a tough time. We are also having a tough time. But we constantly attempt to move forward.

During the recent years we have managed to increase the computer fleet to 470 units. 13 computer study classes with a general number of computers of about 140 units are operative. The computers have also been installed at the faculties, departments, in the libraries and administrative units.

Today, a computer network is operating in the University, including computer classes, free access classes, computer network of the library, individual computers, installed in different University units. Being created on the basis of this network is a single information system, which is to unite all computers and information resources of the Universe. This system is designed for the maintenance of the major trends of activity, namely, organization of the study process, research, operative monitoring and administration. The University network is connected to the world INTERNET to provide access to world information resources. A University WWW-server has been organized, which has a constantly updated information about the University and also an electronic publication *Vestnik Gumanitarnoi Nauki* («Herald of Humanitarian Sciences»). Work is being done on the development of University information resources and providing free access to them.

A MultiMedia Center has been established in the University, provided with the sophisticated equipment to implement full technology on the production of multimedia products and quality video films. The technical equipment includes the graphic stations Silicon Graphics, video equipment Betacam, a digital system for the montage of video films Media 100, etc. During the year of its existence, the MultiMedia Center of the Russian State Humanitarian University has produced two CD-ROMs on the contract of the State Committee for Higher Education, Russian Federation «The Old Images of Moskovia» and «The Higher School of Russia». «Russian Computer Technology». This work is part of a larger project «The Culture of Russian Province», which proposes the production of a whole series of CD-ROMs, video films and books.

In the University library the library information process has been automated on the basis of two *network library systems* TINLIB and MARC for 70 work stations. In 1995 the processes associated with the acquisition and cataloging of the literature have been rendered automatic from *placing an order to a printout of the catalog card.* In 1996 the library and university networks were merged, which made it possible for the readers to use Internet, and the provided access to the data bases of the library to the faculty and the students. Today, work is being done to open a meadiateque for several work stations, each having multi-media equipment for independent studies (computer, CD-ROM, TV-set, video recorder, etc.).

Each graduate of the Russian State University for the Humanities is to know *two foreign languages and to be able to use the computer.* But the informatics education of a specialist in humanities and informatics (working in a humanitarian area) is based on the fundamental courses of theoretic foundations of informatics differ.

The variety of the problems resolved *by all* University graduates presupposes the knowledge of a number of software products, whose mastery provides a definite level of computer literacy. These include, for example, the operational systems and media and text and table processors. The level of information literacy is ensured by such courses as «Systems of the Management of Data Bases» and «Information and Linguistic Support of Information Retrieval Systems, «Expert Systems», «Computer Systems and Networks» (including Internet), and also special courses in linguistics and automatic processing of the text.

Practical classes rely on sophisticated software, including Windows 95, Lotus Notes (a system of collective work, document rotation and management of the University), Microsoft Office, etc.

Along with the education of *specialists in humanities,* the University educates highly-qualified specialists in:

- information systems, technologies and resources;
- intellectual information systems;
- automatic archive technologies.

The following programming languages are studied: C++, Pascal, Java, HTML, Visual Basic, etc. Among concrete network technologies Unix, Windows, and Novell are used.

The University graduates are prepared to work in such increasingly required areas as information systems, data banks and data bases, system of enterprise management, etc. But the level of the problems they solve depends not only on their education but also on their individual capabilities and inclinations.

We pin certain hopes on the recently established Study and Research Center *The History of Science and New Education Technologies.* The computer equipment of the Center makes it possible to work on a highly professional level. As early as today we can provide our data bases and original methods and schemes of the education processes and original software products.

I am glad to tell you that we manage to do something in our conditions, but I primarily want to state that the University is ready for serious cooperation with the world centers of humanitarian education. I would think that I am not wasting your time if I could convince you, esteemed members of the UNESCO Congress, that partner relations with our University would be interesting and useful to them.

In summary, I would like to invite Congress members to the seminar «Information Technologies and Humanitarian Education in the Russian State University for the Humanities» at 14.30 hours. We shall try to tell you and demonstrate at this seminar how new information technologies are applied in humanitarian studies and education.

Commission II

THE EVOLUTION OF INTERACTIVE MULTIMEDIA: MOTIVE FORCES, USERS, PRODUCERS

Régis Poubelle

DIRECTOR OF «PDO MEDIA»
HONORARY PRESIDENT OF THE FRENCH ASSOCIATION
ON THE DEVELOPMENT OF MULTIMEDIA

INTRODUCTION

The concept of interactive multimedia of operative access and independent or electronic editing is based on the variety of methods to derive and use information.

This variety is quite obvious in the area of tutoring and learning games: on the one hand as two ways to receive information both collective and individual and two ways of use (educational classes close to the traditional form, centers of documentation and information (CDI), libraries, home computers), on the other hand as two modes to receive information - on-line and off-line.

THE EVOLUTION OF INTERACTIVE MULTIMEDIA

The concept of interactive multimedia is not new. These means have been used in the process of teaching and learning in various ways depending on the given subject since 1970s. Computer tutoring is the most striking example of the possibilities of using technical means in originating new methods to transfer knowledge. This applied training tool enabled at various stages of its application to develop models for students to carry on dialogues to be adapted to the given level of knowledge. Computer tutoring which first appeared in '80s was widely applied in medicine, engineering, vocational training, especially in the cases when the use of visual methods was essential. At the same time the potentialities of personal computers made it possible to develop interactive programs including multiple-choice quizes. The text information was removed from carriers to monitors of personal computers linked to the external sources of image and sound. This type of combined multimedia presented certain difficulties and consequently it was discarded.

When hardware came into use which are capable to integrate the text, graphics and sound and a little later the fixed image as well as peripheral devices for data retrieval and the author's tools, independent integrated multimedia technology came into existence. The new conception has many advantages:

- the author's tools enable to carry out specific developments and to adapt the contents for the needs of learning, and at the same time they grant him more freedom to create;
- convenient in use uniform carriers (CD-ROM, CD-I, Photo CD, Portfolio) ensure a high degree of independence;
- excepted standards guarantee an opportunity to use any reading device.

Nowadays integrated multimedia technology is widely used both in tutoring and developing of teaching games.

However, despite the numerous advantages of application of this technology in the sphere of education its possibilities are limited. A number of researches conducted in the USA and Europe in the CERN Institute (Geneva), in particular aimed to solve the problem which worried scientists all over the world: to grant access to information in on-line regime. Thus Internet came into being. Created for purely scientific purposes, later it spread to the area of education.

Operating in on-line mode interactive multimedia technology is the result of the transfer of the hypertext to information networks. Since recently the extension of HTML-share used in Internet as compared with units which collect only documentary information given opportunity to make interactive and applied pedagogical means compatible.

The main advantages of operatively accessible multimedia technology in comparison with interactive multimedia lie in the possibility of remote data transfer to a great number of users and the possibility to work in on-line mode. At present it is mostly used for distance tutoring and also in search for documental information.

WHAT STANDARD FOR WHAT SOFTWARE

Whichever are the methods of operation of software is it possible for it to meet identical requirements in various kinds of use?

The designers try to take into account the whole set of generated need offering in particular new production standards for example for high-density compact disks (DVD) which will enable to remove a number of existing technical restrictions including those for video. But the role of professionals in this field is reduced to suggesting alternative approaches, whereas it is the market that has the right to make a final choice. In this connection expectations placed by the teachers on the developed standards and means to transfer information are of particular interest for electronics. What hopes do the teachers have concerning applied interactive multimedia programs operating independently which are granted by networks such as Internet with such independent carriers as CD-ROM, CD-I, Video CD, Photo CD? Do they have the needs similar to those of general public and professionals?

Can the transfer of information in operative mode by Internet become the working tool for the teacher or does such use only remain within the bounds of search for the necessary documents?

The possibilities of using Photo CD for tutoring as well as using CD-I in the field of vocational training have been discussed more than once but the final answer seems not to have been found yet.

CD-ROM and Internet are probably the best among the carriers existing today but new standards of technical maintenance, which are sure to appear before long, should meet the following requirements: speed and low costs of modernization, 'friendly' interface, the possibility to be used without special training, the capability to combine sound, fixed and moving images, high-resolution and also the quality comparable of magnetic tape record. All this presupposes that future digital parameters will exceed todays' performances of compact disks and telecommunication networks with high throughput by ten times.

THE CONTENTS AND THE PURPOSES

The contents of multimedia products have become the subject of frequent critical discussions. We should doughtless contribute to the collective speculation on the topic in a more constructive way. Nowadays the market offers hardware and software means the quality of which is constantly improving, but the share of products with the author's contents and those meeting the needs of learning and vocational training remains limited. The character of multipurpose product testifies to a rather vague knowledge of real needs in the field of teaching and learning among professionals in software, i.e. software creators, designers and producers.

What are the requirements of educational sphere to software/hardware of general use and of special use, in particular? Which of them are best brought into line with the concrete conditions of teaching? Will optical carriers be more often used in the classroom (or in its future substitutes) or will they be mostly preserved in centers of information and documentation or in libraries? Is the traditional way to create training appliances for secondary and high schools suitable for electronic means, and will it help to individualize education and to begin working life?

LEARNING MULTIMEDIA

In view of such complicated and ambiguous situation the designers of electronic means are confronted with the problem of choice of a possible strategy.

First of all it should be specified which carriers are more suited to application in education and for which uses. This is very important because when commercial purposes are not quite definite it impossible to plan the strategy of production.

Passportization is another important point. Is the given project intended for home use? Does it present any interest for pedagogical purposes, for teaching and learning? There are no criteria which enable to answer these questions.

There is another question. Does education need the so called «vertical» applications similar to those which are used by professionals? Can we speak about an application strictly suited to the definite pedagogical need which is created for education in cooperation with professionals? There is no quite definite answer to the question, but teachers might take part in there development as has always been the case when schoolbooks are published. The international character of the multimedia market should also be taken into account, it can not be ignored.

21st century will be the age of interactive multimedia and, first and foremost, the age of electronic communications on a world scale. The whole world will be able to communicate as well large family either through networks or with the help of independent means. As for the sphere of education successful development of learning multimedia products will probably depend on there ability to ensure individual approach in teaching and learning the individualization of educational courses presents a serious problem for teaching and learning. Which means wilL be offered to schoolchildren and to students in the future? How to ensure an individual approach in education?

USE OF TELECOMMUNICATIONS IN EDUCATION AND SCIENCE IN THE REPUBLIC OF BELARUS

N.I. Listopad

DIRECTOR, COMPUTING ANALITICAL CENTRE,

S.V. Kritsky

MINISTRY OF EDUCATION AND SCIENCE OF THE REPUBLIC OF BELARUS

The acquiring of sovereignty by the Republic of Belarus and its economy transition to the market principles challenged the changing of the traditional principles of the society's organization. This has touched the system of information supply of educational and scientific and research sphere. Higher educational institutions, academic and branch institutions have to agree the level of their developments with the world achievements. There has appeared the need for a new system of information services, based on the up-to-date means and new information technologies.

The introduction and use of new means of computer telecommunications in education and science is very important for the Republic of Belarus. Computer telecommunications provide a unique opportunity of the overcoming of informational and organizational separation of scientific and research organizations and the problems in the publication and dissemination of scientific results and ideas and integration of the Republic into a world system of education and science.

Computer telecommunications are an efficient and fairly cheap means of information exchange, which permit development and exploitation of the national intellectual potential and provide access to global information resources.

At present, there are a number of global computer networks operating in the Republic of Belarus as BelPAK, RELCOM, SPRINT and others. However these networks are not designed for education and science and their services are either expensive or limited.

Taking into account the needs of science and education the UNIBEL network is being developed in Belarus, which unites the leading research and education establishments and offers major communication and information services to provide a basis for the development of scientific and educational networks in the Republic.

The UNIBEL network is based on a hierarchical approach. The infrastructure nucleus is the central node (in the long run it should be a powerful multiprotocol network node), which provides uninterrupted operation of the network, routing, links with international global networks, primarily with Internet. An important place in the UNIBEL structure is occupied by regional nodes, which form a second level of hierarchical structure. The regional nodes are created on the basis of the most advanced higher education establishments so that to ensure the operation of the other network nodes and terminal users. It is proposed that just these regional nodes will become centers of the distribution and introduction of computer telecommunication and network Internet technologies in education and science spheres.

To provide access of higher educational establishments and organizations to information resources of the Internet global network in Minsk has initiated, being supported by the Soros Foundation, implementation of the project on the establishment of the fiber-optic BACKBONE. In accordance with the given project, the terminal equipment will be installed in city telephone stations, which will provide optimal conditions for the connection of the users. The Project also envisages a satellite communication channel for entry into Internet.

Establishment of telecommunications in education and science system of Belarus is impossible without a pre-development of local computer networks. The most illustrative example of this approach is the Belarus State University.

One of the key issues to the development of the Belarus State University is the refining of its information infrastructure. The information structure of the University is to develop along the following directions:

- development of a high-speed University network of data transfer to link the rector office, dean's offices, departments, library, classrooms and integration of this network into Internet;
- development of methods of distance education;

• development of an automated system of University management.

The development of the united general-University high-speed information network of data transfer being the first priority, the University has stated the following objective of the establishment of the united computer network:

- provision of a quick access to Internet to researchers, graduate students and students of all departments;
- development of the united University information system with information exchange between the computers and access to general University data bases and electronic bibliography catalogs at the rate of up to 100 Mbit/sec;
- provision of the operation of an automated system of University management and development of a paper-free technology of information transfer;
- obtaining of technical base for the teaching modern network computer technologies to students and graduate students;
- access of teaching computer classes to network software and also information exchange between the networks of classes.

The concept of the united University computer network comprises integration into the Internet international computer network; integrated solution of the problems of teaching information support, research and management on the basis of the united computer network; free access to information resources of the network of teachers, researchers, graduates and students, using software and hardware for delimitation of access rights.

The data bases currently available to the University network users, the software used in the network are designed to solve the problems of information support of education and researches and also the operation of the automated system of University management, one of the best developed in Belarus.

A teaching classroom for to study modern network computer technologies is connected to the network. The workplaces of this class have Internet access in the on-line regime. One projects implemented on the basis of this classroom is concerned with the development of teaching courses on the system of Oracle data base management.

An important aspect of support of the educational and research activity of the University is access to research and educational information. Library workers maintain electronic catalogs of books, periodicals and subscriptions. The file server also maintains a periodically updated copy of electronic catalog of the library of the Moscow State University. This information is accessible to all the network users, including workstations in the bibliographical hall of the library. In addition, thanks to the support of the European Communities in frame of the TEMPUS project an optic juke box of 6 CD-ROM drivers is installed as well as a constantly replenished set of laser disks of the institute of Science and Technological Information (INIST), France, available to all the network users.

The main principles of the development and operation of the automatic system of University management elaborated since 1991 are:

- introduction of paper-free technology of information transfer in University services;
- provision of automated management system workstations to personnel of all levels: from rector to a personnel department inspector;
- joint technology of the use of information by different university services, excluding duplication of the entry of information and providing its integrity and authenticity.

Today the automated University management system has the following network subsystems:

A) *«Matriculant», «Dean's Office - Students», «Scholarship».* These network subsystems ensure a bound technological cycle of the processing of information about University students, including the feeding of data on University entrants and the results of the entrance examination, preparation of an order of the enrollment of students and handing over the list of students to the faculties. At the faculties student personal card and progress data of students are maintained over the entire study period, and scholarships are issued. On the basis of this information, the accounts department calculates scholarships, indexing and other payments, handing over information to the accounts center of Belbisnessbank to credit student's accounts.

B) *«Staff», «Salary».* Information about University members is maintained in the Personnel Department in the «Staff» subsystem, which permits maintaining individual forms, salaries, bonuses, combining of jobs, etc. This information is used in the «Salary»;
subsystem.

C) *Information subsystems.* This group includes subsystems, which permits the Rector's Office to have urgent access to information and taking justified decisions. There are the following subsystems operating in the network: «Registration of Incoming and Outgoing Documents, Control of the execution of Orders and Instruction», «Registration of Material Values», «Registration and Payment for Telephone Conversations», «Foreign Students, Graduate Students and Fellows» and a number of others.

The set of organizational measures is of great importance — without them an introduction of an automated system of management is inefficient. These primarily include reduction of the managerial personnel by dismissal of unqualified officials and training of the personnel modern computer technologies.

The existing possibilities of the University network do not permit access to all subdivisions and interested persons to international and university information databases. For that high-speed communication channels are needed both within the campus and between remote units. The University Computer Center studied the needs of services and units for access to information, the information flows were analyzed and a project envisaging integrated development of the University Computer network was worked out. The following basic lines of developed are proposed under this project:

- in each faculty (building) workstations are merged into a single or several local networks. The topology of each of these networks is so designed that it can be readily expanded with an increase of the computer equipment stock. In case a server is absent or is deemed unfeasible to install it in the building, the workstation can be merged into individual segments;
- all the University buildings located at a distance of up to 2 km from the main building are connected to the main building with a fiber-optic cable to ensure the rate of information exchange up to 100 Mbit/sec. The terminal fiber-optic equipment in each building is an intellectual bridge that would ensure connection of local networks and individual segments to the backbone and cable and the distribution of network traffic;
- the buildings in the University branch, which is 7 km away from the main building in a straight line. are united using radiomodems;

- integration of the University local computer network into Internet, ensuring its connection to the UNIBEL network via fiber-optic channel.

Taking into account a considerable research and technical educational and industrial potential, Belarus has a good chance of entering the world information space, and it can become an enjoying full rights participant of the world community of global computer networks.

Discussion

NEW EDUCATIONAL TECHNOLOGIES AND THEIR PROSPECTIVE EVOLUTION

Alain Meyer

REGIONAL CENTER OF TELEEDUCATION
NATIONAL SCHOOL OF ARTS AND CRAFTS (CNAM)
(FRANCE)

1. NEW EDUCATIONAL TECHNOLOGIES: DEVELOPING REALITY

Since the middle 60s experts in the field of education have begun to associate the terms «technology» and «education». Doing so, they sometimes mix two conceptions: the conception of technology in education, which presupposes the use of computers and technical means in the process of learning, and the conception of technology of education when scientific principles are worked out for improving the efficiency of learning. The first interpretation began to be introduced in the 70s especially as result of the introduction of informatics as an additional pedagogical means. This tendency is reflected in a great number of examples. The great spreading of microcomputers caused in the beginning of the 80s the abbreviation EAO (*Enseignement Assistée par Ordinateur* - computer education) and its derivatives, such as FAO, EIAO (*Formation Assistée, Enseignement Intelligement Assistée*). In the middle 80s the Anglo-Saxon term «New Information Technology» (NIT) translated into French coined the expression *«Nouvelles Technologies Educatives»* (NTE)(New educational technologies). In a way we have come to use again the terms of the 60s. Despite these changes in terminology one should hope that the language used or the newly coined words make it clear for those who use them that the global approach is essential in education taking into account how complicated the process of learning is.

Taking into account what was said above the abbreviation NTE will stand for practical performances, statements, methods, means and skills *(Technologies)*, including means of communication, the creation and exchange of information which are developing now *(Nouvelles* - new) such as telecommunication networks, and digital or analog devices used as educational tools.

2. HOW TELEEDUCATION IS ORGANIZED IN CNAM, PAYS DE LA LOIRE REGION. FRAGMENT OF OBSERVATION

In April, 1987 The Regional Center *(Centre Régional Pays de la Loire)* CNAM made the first entry about the first 'telestudents'. Since then more than 2,000 people have become 'telegraduates' with the help of the organization which is now the Center of tele-education and pedagogical innovations *(Centre de Télé-Enseignement et d'Innovations Pédagogiques - CTEIP)*. The reasons for the creation of such an original Center and its development are worthy to be given a brief description.

Considering the special group of population which uses this form of education (it mainly consists of those working in offices and enterprises) an educational institution usually conducts evening classes. This limitation often requires of the students to be able to use their intellectual potential after a working day. Besides, when using educational stations the students should be able to meet their professional demands; the geographical distance should also be taken into account.

CTEIP was set up to ensure any user who lived far from big city centers (where CNAM centers - *Centres du CNAM* - are mainly operating) the access to high-quality education to be able to receive a diploma. It was founded with a video that the originators of the project coned 'cultivate' the territory in educational terms.

Actually, technological improvements have led to the ideas about new approaches to education in the regional center CNAM. At the present moment these ideas are exerting influence on the set of friends of the Center's activities. The development of the new methods which grant more initiative to the student and enable him/her to chose their own rhythm and strategy of learning, have soon become an important objective for the CTEIP administration. These methods are to ensure more efficient education than by traditional methods when students are actually present in the classroom.

2.1. Principles of operation

Breaking with the «traditional» distance education method and its pedagogical shortcomings, CTEIP's executives have developed the method which uses five situations in the process of learning. The student and ... the teacher make their choice of the alternatives. The variety of such situation is intended to keep up the motivations for learning, includes 'transfer', 'reception' and 'exchange' in the process of learning. Their brief description is given below.

Individual self-training: once a week students meet each other in a classroom located nearly, which is granted to them by CTEIP. Such collective meetings give an opportunity to exchange knowledge, to look through the contents of work set for everybody and also to support each other. The classroom are equipped with computers, and during their meetings the students work on them. In this case they have access to the main educational software used in the interactive mode and which is centered in CTEIP, through communication software which is called TeleSITE. Such method of learning without the teacher enables the student himself/herself to evaluate how well he/she knows the material and represent some conceptions visually. Despite the fact that following this method a student works on his own, it gives him a chance of collective discussions and finding answers to important problems.

Telemanagement: students receive additional information through TeleSITE (individually and collectively) from the teacher and from some other groups. These explanations are supplemented by the exchange of multimedia information and the possibility for teacher to receive information on the remote display. Such method of telemanagement is realized in on-line mode or in off-line mode (when messages are sent).

Distance conferences: integrating audioconferences and the simultaneous transfer of information to several working stations equipped with computers enables the teacher to give concise explanations of some difficult points in the teaching materials. (The conferences lasting 30 minutes each are conducted for six weeks).

Joint groups of teachers and students: such joint groups organized every eight weeks, seek to maintain contacts created in the process of 'teletutoring' (they are marked by relaxed atmosphere, spontaneity of exchange, etc.). This brief description shows the mixed nature of the system (isolation - regrouping - presence) offered by CTEIP which is based on the concept of «accompanied self-training» *(«d'autoformation accompagnée»).*

2.2. Practical performances

To ensure its operation in real economic conditions CTEIP employs local people to operate equipment (machines, rooms) which are easily accessible for students. These people are on the stuff in lycees, other educational establishments, mediateques, commercial structures. Relying on their help STEIP can offer tutoring everybody who wants to get using modes 2,3 described earlier. These local associations are CTEIP's branches *('antennes',* the so-called 'antennas').

The branches can accept 12 students at a time, they are equipped with personal computers which enable to work in Windows, are integrated to the local network Ethernet. The set of equipment also includes the monochrome scanner and two or three printers. These local networks are connected to the network ISDN through the gates. The equipment can also operate in the mode 'isolated computer'.

The center CTEIP is equipped with the local network with the «tutor»-stations, linked to «pedagogical» server. This complex itself is connected to the network *«Numéris»* through the gates. To reduce potential difficulties connected with the device which makes it possible for the fourteen remote branches to be simultaneously linked with the server.

By individual self-training students accumulate knowledge from various sections of the course. Using this method of learning they receive printed materials (more seldom in electronic form), printed materials can be the book selected by the teacher, supplemented by the outline of lectures or by a special document worked out especially for distance learning. At the collective self-training lessons students use learning interactive software, which are kept at the central server in Nant. This software is intended for:

- the presentation in dynamic mode some investigated problems with the help of printing equipment;
- automatic evaluation of knowledge using sets of questions, instructions and answers.

During this sessions students ask the teacher to explain or to give additional information pertaining to the subject - matter they are learning. If the teacher is free, the telephone conversation begins; if it is necessary this talk is supplemented with the exchange (through TeleSITE) or digital documents (for example, to interfere in the development of the program), the teacher undertakes the control of a remote computer.

In case the teacher is busy (for example, engaged by another station), the student can transfer messages to inform the teacher about the difficulties and to let him know that he wants to communicate with him. This asynchronous mode of transfer is also used in any cases when the exchange of information is not urgent. Students can use educational stations when they are free, at the time which is not allocated to the given subject. In this case they use educational data base which is kept in the mailbox of e-mail.

3 THE DEVELOPMENT AND OPERATION OF NTE IN CTEIP INCLUDING USERS BEHAVIOR

Then, within the framework of research work we pass to the analysis of the operational modes and the usage of NTE, especially on CTEIP's territories. The purpose of this research is to single out the considerable improvements which can be ensured when NTE are used, to develop an algorithm of the users' work or to find out the «borderline» level of competence (as compared with the level of competence which is set for continuous education). Although this research is far from being completed and its results cannot be presented, however it maybe interesting to give some information about the work which has been done mentioning the people taking part.

3.1. Students

First, we shall note what specific skills can the student get and develop in case he uses NTE and to what activities are this technologies applied.

One characteristic feature of NTE is that they are used for self-training. This method to acquire knowledge mobilizes self-control to be able to organize one's learning, to define one's aims, to analyze one's difficulties, to find a solution and, at last, to make a decision depending on the circumstances. Besides, depending on the educational means offered the student can find himself in a situation when he has to decide upon his own approaches to learning (the choice of the method of reading of printed materials, of listening to the audiotape, the use of software). Thus, he can optimize the rate and the time of learning. In this case he «seas» his process of learning and consequently can develop metacognitive abilities.

As the student consciously begins to include some functions into the process of acquiring knowledge the operation of NTE can result in the need to have the function of evaluation and critical discussion; this functions can be realized by the system itself of by external elements. Even if NTE can really help the student in the evaluation of the acquired knowledge (for example through the interactive software) the student who is learning on his own should also define and introduce his own methods and algorithms of evaluation (asking questions in automatic mode, reformulation, etc.). At another level educational materials themselves can bethe source of exercises for the analysis of information: the task of 'decoding' of the videoprogram's images at the rate they are received can serve as a very good exercise in educational and methodological terms. Nowadays, in technical terms certain standard algorithms of information coding are used and therefore the unique access devices of the unique type are used as a very good exercise in educational and methodological terms. Nowadays in technical terms certain standard algorithms of information coding are used and, therefore, the only type of access devices is used, i.e. multimedia stations. Used for learning, for distance learning in particular, this means has no limitations. In this case one should ask himself, if this equipment, apart from mere technical skills, stimulates the student's thinking. The computer can offer, for example, to simulate the reality or represent the 'virtual' worlds for the user to travel in. These new situations which do not necessarily make the person to use his imagination, result in the need to use special control in accordance with the reality, and it should be born in mind when implementating the conception of educational equipment. At the same time the sphere of application of software remains limited for the user because of technical difficulties, although it is open for new scenarios. This situation is unavoidable when the situation is real and its nature is more complicated than the nature of the educational scenario, the student has to identify, to use accumulated knowledge and to analyze information which is necessarily new to him.

NTE also makes it necessary to define and take into consideration new types of relationships between the students. In the cases of collective self-education (independent working groups using a centralized resource), organization of virtual groups (through telecommunication networks), organization of teleclasses the nature of relationships between the participants in the process of learning acquires a specific character, particularly concerning the required means.

The results of the analysis of the working process show that there hardly is the 'student' in the classical sense. The variety of the learning environment, individual situations and the personalities of the students presupposes the necessity to make groups of students according to their abilities to solve some problems mentioned above.

3.2. Teachers

Now let us consider the relationships between the teacher and NTE. The use of NTE certainly changes the student's learning, but the teacher can also acquire skills in some areas.

Therefore, to organize the educational process when NTE are used, the teacher should engage his store of knowledge to evaluate the potentialities of a technology, for example, to be able to choose a suitable one. The traditional learning and the learning using NTE differ both in the stages of preparation and in the stages of the transfer of educational data. At the preparatory stage when the teacher is thinking about how to present the material he should, of course, work in cooperation with the group of professionals on informatics, ergonomics etc. (the members of the group can come and go as need arises), to get with their help an efficient «translation» (the representation of the material being taught) which is in accordance with the pedagogical criteria. In this case a large volume and the difference in the levels of qualifications result in the necessity to clearly define the areas of work. In some cases the teacher has to supervise in development of the system himself and consequently to be at the head of the project. Besides, if hardware is used in the project to represent the contents of the material then the processes of teaching and learning become asynchronized. The situation demands a priori to define the scenarios how to transfer knowledge, this process cannot be adapted at the stage of teaching because of the chosen method. From this point of view the main qualities required of the teacher-designer are creative abilities and punctuality. The implementation of educational means is long process. The teacher-designer have also to integrate devices, scenarios, production developed by other professionals, and this process seems to be more complicated than when traditional teaching is realized. The stages of education, choice and then the integration in one's own strategies can be regarded as a new kind of activity.

If telecommunication networks are used, at the stage of transfer the teacher should learn to take into account the influence of such parameter as the distance: for example, to adapt his speech even if he cannot see his student. If to master a material it would be better to use hardware the teacher or the educational institution should also solve the problems of support. That is realized depending on pedagogical and psychological situations and on motivation. Another point which should be considered is granting the teacher the opportunity to conduct distance .teaching due to the use of technical means: in this case he does not transfer his own knowledge directly, but he can supervise the process of learning and the realization of pedagogical strategies which he chooses.

At least, the teacher will use NTE to develop new methods to evaluate acquired knowledge and new methods of teaching. It should be noted, that from the teacher's point of view the use of NTE divides his job into a number of different functions.

3.3. Educational Institution

In the case of 'traditional' education the role of an educational institution in the process of teaching is mainly connected with the organizational problems and evaluation of the results. The use of NTE changes its areas of participation in education. The role of an educational institution is determined equally by the chosen operative model, production or the integration of educational means, as well as by the methods to transfer data to the students. When using NTE, besides non-pedagogical function, which are present in the classical system, there are additional functions of managing the relationships between the participants in the process of learning, monitoring software, and setting technical problems.

First of all when a decision about the use of NTE an educational institutions often examines economical issues: initial investments, the cost of maintenance, the expected savings of funds, which makes it necessary to develop methods to evaluate the results and the influence of parameters on the results.

The main functions considered above are given on the scheme, we are well aware of the fact that the set of functions is not exhaustive.

4. THE EXTENSION OF THE AREA OF NTE APPLICATIONS

In recent months the use of new technologies in education has been on the increase very much, especially in offices and at business. The number of congresses and seminars devoted to the subject, the realization of European and national programs in support and development of the 'technology and education' projects, the fact, that new commercial structures in ever increasing numbers emerge on the market of educational technologies are indicative of the process. A very fast extension of Internet, good access to devices which use these technologies (multimedia computers), considerable progress in ergonomics to improve the user's interface partly explain such extension. We believe that nowadays an ever increasing number of people responsible for decision making and executives in the field of education would be interested to get 'extra' profits from NTE applications. It explains why at present many projects which are at the design stage pass to the stage of realization.

INFORMATICS IN THE SYSTEM OF ADVANCED EDUCATION

K.K. Kolin

FIRST ASSISTANT DIRECTOR IN CHARGE OF SCIENTIFIC WORK OF THE PROBLEMS IN INFORMATICS INSTITUTE (RUSSIA)

1. THE WELFARE OF THE NATION AND ADVANCED TECHNOLOGIES

The conditions in which people live at the turn of 21st century call for a new strategy in the evolution of mankind based on knowledge and highly developed advanced technologies. Information technologies should be given the top priority, because it is these technologies that serve a catalyst to speed up the process of scientific, technical, social, economical and intellectual development of the community.

The level of technological development of the community determines not only its ability to turn out high-quality production using minimum raw materials and energy, but it gives economic power and social stability to the developed countries and determines the living standards of the overwhelming majority of their population [1].

The powerful stimuli for the advance in technologies in modern society are the ever increasing automatization of industry, wide-scale cooperation and international division of labour, stiff competition between manufactures. Increasing labour productivity and the impact on the output of production, as well as on the new kind of the world market - the market of technologies, advanced technologies not only enable to produce the needed amount of high-quality production, but also create an important social effect, that is the saving of the social time of the community. In other words, people enjoy more freedom introducing new technologies, because thus they make more time for other activities. What are the main conditions for successful development and introduction of advanced technologies? First and foremost, it is the advance of science, general and special education, and of the intellectual development of the community. It is these problems that should be given the top priority in the national policy of any state. Those countries which fail to ensure this priority will find themselves at the periphery of the world technological progress as outsiders.

2. INFORMATION TECHNOLOGIES AS CATALYSTS OF THE ADVANCE IN MODERN SOCIETY

As for the need to give priority to the advance in information technologies, it is determined by the fact that these technologies play the leading role not only in the global informatizatiori of the community, but also are «the intellectual components» of other technologies - industrial and social [2].

The most important trends in the social impact of information technologies on modern society are the following:

- making information resources of the community more active,
- making information sphere more efficient,
- changes in the population employment scheme,
- making other technologies (industrial and social) more «intellectual»,
- development of information communications,
- making the community more intellectual, which is the main condition to create a new and safe model of its development based on knowledge.

The importance of information technologies in the solution of the problems connected with national security, from global modeling to fighting crime, is extremely great [3]. The problem of information security of man and society should be given special attention. This is a new and serious problem, which has not been properly studied yet, and which faces humanity in the transition period to information society.

The impact of information technologies in solving cultural problems is increasing. The most important are the problems of preservation of society's cultural heritage, the informatization of creative processes and also new problems connected with building up of cinema culture and cinema art.

The above mentioned characteristics of information technologies are unique and extremly important in the life of modem society. That is why today information technologies are given the top priority.

3. THE CONCEPTION OF ADVANCED EDUCATION

One of the most important and constructive ideas in the strategy of further development of the modem system of education is the idea of advanced education. The main point here is not only to ensure an ever advancing development in the system of education on the background of other factors of social, economical and cultural development of society, but principally to help people from such abilities that will enable them to adapt, live and work successively under new conditions of the coming 21st century. The most important among these abilities are:

- noospheric consiousness,
- system thinking,
- ecological culture,
- information culture,
- creative ability,
- tolerance,
- high morals.

We believe that it is these abilities that will ensure the survival and further steady evolution of civilization. That is why they should be te main goals of the advanced education system [3]. The idea of advanced education belongs to the Russian philosopher, academician A. D. Ursul [4] and it ensues from his philosophic conclusion necessitating the priority of consciousness over existence in the community's transition period to the steady development and controlled process of creation of the noospheric civilization [5]. This idea is especially important and timely for Russia nowadays when the Conception of transition of the Russian Federation to the steady development is adopted and the strategy of the country's steady development is being carried out. The idea of advanced education was touched upon in the National Report of Russia at the Second International congress of UNESCO «Education and Informatics» [6] and it will be assumed as a basis for the state policy of Russia in education. It is essential that not only scientists and experts in the field .of education but statesmen and politicans as well ought to realize the actual need to give the system of education an added characteristic of advanced development which is only natural at this stage of evolution of our civilization. It is on their attitude and practical activities that the implementation of this main idea will largely depend [7].

4. INFORMATICS IN THE SYSTEM OF ADVANCED EDUCATION

At the turn of the 21st century we should be aware of the fact that humanity enters a new era - the era of information. The stability and welfare of human society will mainly depend on how efficiently we will be able to use information as a means of development of our civilization. In other words it is the question of the increased social role of informatics in the life of society, faster technological cultivation of social sphere and, in this connection, the need to use new approaches to informatics in the education system. We should remember that today informatics is not only an important means to support pedagogical process, it is not only a highly efficient teacher's tool, but it is also an important and necessary educational subject.

Born in the depths of science about managing of processes - cybernetics, modem informatics is rapidly expanding its sphere of application. We are the witnesses how from the technical subject about the methods of processing data using computer systems and other information means, informatics is changing into a fundamental brunch of natural science about information and information processes in nature and human society. Today informatics is the most long-term and growing sphere of science in the world, the whole complex of new sciences about informatics is now being centered around it. This complex will form a scientific basis of the coming information society [8]. That is why in the long-term system of education new approaches to training informatics in technical as well as in humanitarian [arts] educational institutions, lycees and colleges are necessary [9].

5. NEW PRINCIPLES OF TRAINING INFORMATICS IN THE LONG-TERM SYSTEM OF EDUCATION

In the National Report of Russia at this Congress the general outline of the new long-term course «Fundamentals of Informatics» was given for the system of advanced education. The course falls into four sections: «Theory of Informatics», «Means of Informatization», «Information Technologies» and «Social Informatics».

All sections have units and comprise several problem units, the organizational structure and contents of which can vary depending on the specialization of the given educational institution. This, for instance, the section «Theory of Informatics» includes six units:

- Philosophic principles of informatics;
- Principles of general theory of informatics;
- Principles of computer cemantics;
- Principles of informational modeling;
- Intellectual information systems;
- Information and knowledge.

This section of the course aims to help students to form modern scientific world outlook, which regards information as a fundamental semantic characteristic of nature, and information processes as the most important components of any technical, social or natural systems.

The second and third sections of the «Means of Informatization» and «Information Technologies» course contain problem units, which consider functional possibilities and the prospects of development of the modem means of informatization in society, their information support, as well as basic and applied information technologies. The material is organized in such a way as to give specialists not only pragmatical knowledge, but a general view about information technology as a new science dealing with the rational organization of information processes. The need to create such science is becoming more and more obvious. The fourth section of the «Social Informatics» course includes four problem units:

- Information resources;
- Information Potential of Society;
- Information society;
- Man in Information Society.

The main purpose of this unit is to give students a full system knowledge about the information character of the development of modern society, as well as about accompaning information problems and the ways to solve them using information approach method and the potentialities of information technologies.

6. RUSSIA'S EXPERIENCE IN THE DEVELOPMENT AND STUDY OF THE PROBLEMS OF SOCIAL INFORMATICS

The «Social Informatics» section is basically new in the given course on the principles of informatics. This course is particularly important for students and postgraduates of universities, humanitarian educational institutions as well as for teachers and listeners in the system of additional higher education.

Social informatics as a separate scientific and educational discipline was first established in Russia, and since 1989 it has been gaining an increasingly wide recognition in the system of higher education. Thus, for example, problem-oriented departments of social informatics have been set up in a number of state universities in Russia and they are operating successfully. There is also a course of social informatics in the system of additional higher education - in Moscow State Social University and in the Russian Academy of State Service under the President of the Russian Federation. Since 1989 scientific seminars and conferences on scientific and educational problems of social informatics have been held every year, and the collections of proceedings «Social Informatics» and «Problems of social Informatics» are published regularly. All this is indicative of the fact that a certain scientific school has been established in Russia to study the problems of social informatics, its activities undoubtedly contribute to the practical realization of the ideas and methods of social informatics in education [10].

7. THE CONTRIBUTION OF RUSSIAN SCIENTISTS IN THE DEVELOPMENT OF INFORMATICS AS A FUNDAMENTAL SCIENCE

In recent years Russian scientists have been active conducting fundamental research both in the theory of informatics and in information problems of the evolution of society. They also encompass philosophic problems analysing the role of information and scientific knowledge in the further evolution of modern civilization and the transition to the stage of steady development of human society. The basis of this research is the noospheric conception of the evolution of biosphere, which is the result of research work of such Russian scientists known all over the world as Tsiolkovsky, Vernadsky, Chizhevsky, Timofeyev-Resovsky. Nowadays this conception is being further developed in the studies of academicians Ursul, Moiseev, Yanshin and other Russian scientists [5].

As for the development of theoretical principles of informatics in recent years, first of all one should mention the studies of such Russian academicians as N.N. Moiseev, A. A. Samarsky, A. D. Ursul, D. A. Pospelov, A. I. Rakitov, R. F. Avdeev and also professors Yu. I. Shemakin, L. A. Tsymbal, and a few others. Serious research in the field is also being carried out by the scientists of the Ukrainian Academy of Informatics.

All this is the illustration of significant results in research in Russia today, which can and must be te subject of systematic studies in the long-term system of education. It is these results that should be the basis of problem units in the «Theory of Information» section which will be a part of a new course «Fundamentals of Informatics».

8. THE INTERNATIONAL PROJECT FOR THE SYSTEM OF EDUCATION «INFORMATICS - 2000»

It would be good idea to carry out a special complex international project «Informatics - 2000» under the auspices of UNESCO to unite the efforts of experts from all over the world to develop and to put into practice new methods of learning informatics in the system of advanced education.

The purpose of the project is to create basic programs for the units in the «Fundamentals of Informatics» course various links of the long-term systems of education using the results of research of fundamental problems in informatics and the teachers' experience gained when using these results in higher and additional higher education.

In the process of the realization of the project the following is to be carried out:

- basic programs for the units of the new course in higher and further education, as well as in additional higher education;

• general program for the units intended for adults;
• manuals dealing with the main sections of the new course.

The project is supposed to comprise a course of lectures (on video cassettes and computer optical disks), by the leading experts in particular problem units of the new course.

The project should be realized with the help of the leading scientists, teachers and experts in informatics, philosophy and sociology from various countries, which have already made some scientific and educational studies in technical and social informatics. It is most important that professors and teachers from universities, technical and humanitarian higher educational institutions and colleges of Western and Eastern Europe, the USA, Canada and Japan should participate in the project. Their experience and knowledge pooled to form basic programs in long-term course of informatics and oriented to train people who will live in information .society would make these programs useful and necessary for the world community.

The development of such programs and their distribution through UNESCO is an important step on the way to practical realization of the idea of advanced education, which is a necessary condition of a further safe and steady evolution of our civilization.

Fundamentals of Informatics

Section 1. Theoretical informatics	Section 3. Information technologies
Problem modules:	*Problem modules:*
1.1. Philosophical fundamentals of informatics	3.1. Basical information technologies
1.2. Principles of the general theory of informatics	3.2. Applied information technologies
1.3. Principles of computer semantics	
1.4. Principles of information modeling	
1.5. Intellectual information systems	
1.6. Information and cognition	

Section 2. Means of informatization	Section 4. Social informatics
Problem modules:	*Problem modules:*
2.1. Technical means of iformatization	4.1. Information resources
2.2. Programmatic means of informatization	4.2. Information potential of society
2.3. Means of informational supply	4.3. Informational society
	4.4. Individual in an informational society

INTERNATIONAL COMMUNITY OF THE DEAF: EDUCATION AND NEW TECHNOLOGIES

Jean Gremion

DIRECTOR OF THE INTERNATIONAL
VIDEO-COMMUNICATION PROJECT

INTRODUCTION

As noted in tne Introduction to the Education and Informatics: Proceedings of the Second International Congress *(held in Moscow, Russian Federation, on 1-5 July 1998), recent years have witnessed "remarkable development in information and communication technologies, whereby hardware and software 'generations' have rapidly succeeded each other and, in the most innovative manner, have converged with other technologies. "*

Since new information technologies (NIT) can lead to the design of a practically unlimited number of new information channels and networks, particularly through the use of digital and informational combinatorial devices which allow for communication of large volumes of visual information, and also considering the fact that the universal type of communication for the deaf people is visual communication (primarily the sign language), new information technologies are called upon to play a significantly important role in the transformation of the traditional methods of education of the deaf.

The international community of the deaf people numbers some 200 million people (children and adults, suffering congenital or caused hearing impairment, born of deaf or hearing parents).

In the early 1990s, the only information communication channels that the community of the deaf people had at their disposal were the devices for telephone sound recording - of the TTY type in the USA and Minitel in France. The community was, therefore, cut out from the majority of audio-visual information and communication channels used in the hearing world.

Now that we are approaching the beginning of.the third millennium, the advent of new communication networks (video-conferences, dialogue television, computerised workstations, pictorial languages, direct communication via Internet, etc.) has made it possible for the deaf people, for the first ever time in history, to communicate and express themselves by means of VISIBLE SPEECH, VISUALLY at the planetary scale.

This profound change taking place in the international community of the deaf signifies a total rejection of old the system of education of the deaf. Adopted at the 1880 Milan Congress, which has become inadequate for the purposes of teaching using new information technologies.

NEW INFORMATION TECHNOLOGIES - A HISTORIC CHANCE FOR THE INTERNATIONAL COMMUNITY OF THE DEAF PEOPLE

The development of new information technologies has led to a fundamental change in the methods of conveying knowledge the deaf people in the process of their education, the significance of which is comparable to the change in the methods of knowledge transfer that the appearance of the printing press had for the hearing world.

Deaf people, as is well known, communicate with the help of sign languages which have developed over many centuries, and which have certain regional and national distinctions.

Just as the speech of the hearing community, sign languages, possessing their own vocabulary, syntax, grammar and variety of styles, can in full the requirement for self-expression and communication among the deaf people.

Since the deaf people's perception of the world is entirely visual, the combination of signals and the syntactic rules used to produce communication are radically different from the rules governing the production of spoken communication by the hearing people. The sequence of signs is dictated by the logic of perception and inception of concepts, instead of the existing structured logic of the hearing, people language.

It had taken nearly a hundred years after the International Congress of 1880 in Milan, where the majority of the participants, comprising hearing teachers of the deaf, adopted a barbaric decision to prohibit the deaf the use of their own language and any form of cultural self-expression using their language, for the hearing community to admit, at last, the fallacy of the approach based on cruel and ill-fitting methods of forceful integration of the deaf into the hearing world.

We might say that at present the historical opposition between the proponents of speech education, on the one hand, and education based on sign language, on the other, has abated.

Most of the current policies toward the education of the deaf, whether regional, national or international, are based on the concept of dual culture seeking to bring the two worlds together.

As more and more communication and information bridges are built between the world of the deaf and the world of the hearing, it becomes increasingly clear that the progress of new information provides a historical chance of overcoming the gap which has always divided the two worlds.

TECHNOLOGICAL DEVICES AND THE DEAF

Now that we can make use of "information auto-routes" (some of which, like, for example, Internet, are based on recurrent dynamic information routing over telephone circuits), it is pertinent to draw attention to the fact that we have to thank Alexander Graham Bell, Scottish-born scientist and teacher, for the invention of the first information channel - the telephone, which had been prompt by his desire to find a means that would allow communication between hearing and deaf people.

Alexander Bell was born on March 3, 1847, of a deaf mother, communicating with the world with the help of lipreading and sign language, and a hearing father, an authority on elocution and speech correction, whose desire was to develop a universal language allowing unhindered communication of all people, hearing and deaf alike.

In 1871, Bell started lecturing in Boston on teaching speech to the deaf. He later fell in love with one of his deaf students, Mabel Hubbard, the daughter of a powerful man, the Massachusetts senator, who was later to become his wife. His future father-in-law assisted Bell financially in his research toward creation of an instrument for the transmission of words.

We owe Bell several inventions and innovations, among them a multiple telegraph, following which, in March 1876, he patented "the method of, and apparatus for, transmitting .... sounds telegraphically by causing electrical undulations similar in form to the vibrations of the air accompanying the said vocal or other sounds". This signified the invention of the telephone.

Working on the telephone, Alexander Bell had in mind an instrument that was to make him closer to his deaf wife, but ironically, achieved quite the opposite, instead, for the invention of the telephone increased the distinction between the hearing and the deaf, just as the operation of the Bell Telephone Company, one of the most powerful in the world, further widened the gap between the world of the hearing and the world of the deaf.

It happened, first of all, due to the deaf people's inability to use a telephone. But also because the Alexander Graham Bell association for the Deaf promoted a new policy toward the education of the deaf, adopted by the 1880 Milan Congress.

As a result, the community of the deaf had for over a hundred years been barred from the use of communications based on new visual technologies. Now again they are facing a new world which was brought about by the development of new information technologies.

The deaf community are challenged by the appearance of new technologies in the area of information and communication.

The degree to which the new technologies can ensure video-communication over short or long distance is the degree to which, for the first ever time in history, the knowledge accumulated by the hearing community becomes available to the deaf.

Even now, the application of new information technologies makes it possible for the deaf to introduce radical changes in the social and cultural system of their vast community.

This historic development in the culture of humankind must speak to the conscience of those in the hearing community who are in charge of the development and implementation of the policies toward the education and training of the deaf. But even more so, this refers to those in the deaf community who are responsible for the cultural heritage of their own community.

DIRECT COMMUNICATION BETWEEN DEAF PEOPLE OF DIFFERENT NATIONALITIES

Unlike the hearing, the deaf can communicate without the assistance of a translator. This possibility of communication in an internationally understood language is one of a real treasures owned by the international community of the deaf. Indeed, all the languages of bodily movements employed by the deaf community of the world have five shared parameters: configuration, direction, position, facial expression, movement of the hands.

Since every national language of bodily movements comprises several thousand signs falling within this linguistic law of parameters, it is easy to understand *how* great are the possibilities of communication through bodily movements familiar to all.

Such an international language of bodily movements can include:

- original, close to mime, movements (which are often the first sign language elements to appear in any national sign language; thus, a hand movement uniting the mouth and the ear is universally understood as the sign pointing to deafness);
- movements common to the majority of countries;
- spontaneous movements, meaningful only within a specific context;
- drawing movements;
- signs and phrases loaned from the interlocutor's language (as when a deaf Chinese uses a Chinese sign during a communication with a deaf Frenchman: if the latter cannot understand the used sign, he would ask the Chinese to explain its meaning or to choose an equivalent sign; if he does understand the sign, he would right away introduce it into their communication);
- non-verbal communication signs, such as silence or exchange of glances).

For the deaf of the world the sequence of signs in a "phrase" has less significance than their spatial position and the accompanying movements. The deaf nearly never use the subject-predicate-object phrase structure commonly used by the hearing speaking Romanic and Slavic languages. The deaf tend to use the subject-object-predicate structure (most commonly), as in the Turkish and Japanese languages, or the object-predicate-subject structure, as in the Malagasy and Polynesian languages.

While the same syntactic combinations are used by the deaf world over, the finger signs are dissimilar in different nationalities.

The finger alphabets of the French, Americans, Belgians, Dutch, Swiss, Nanes, Swedes, Italians, Portuguese, Argentines, and Brazilians requires the use of the fingers of one hand, while the. English, Irish and Australians use the fingers of both hands.

Written alphabets differ from country to country. The number of finger signs used is 24 in Greece, 26 in China and in the countries of Romanic languages, 32 in Russia, 33 in Iran, 39 in Poland, 43 in Israel, 46 in Japan, etc. In 1973, the Sign Unification Commission of the World federation of the Deaf attempted to code these international movements within one international system - the GESTUNO language.

Currently, the Federation upholds the view that the wealth of communication means employed by the deaf does not allow to codify them within a single international language, and is therefore inclined to leave it to the community of the deaf to decide the destiny of of this language of international communication which is undergoing constant change and transformation. It is clear that rapid progress of the new informational technologies will in the years to come produce a veritable "leap" in the development of the international language of the deaf community. Already, there are there exist numerous international circuits within Internet for communication of deaf people of different countries (such as, for example DVWV). Still, the communication via these channels is carried out using written languages of the hearing (primarily English and French).

In future, due to the transfer of images via new information auto-routes, deaf people will be able to communicate using the movement language (input of video-data in the network, direct information exchange by real time processing, dialogue television networks, etc.).

As for the practical availability of required equipment, training and access to NIT for national communities of the deaf, it must be admitted that some of them employ the opening possibilities of using new information technologies in full.

In view of this, final documents of the present Congress must contain recommendations worked out by the persons, hearing and deaf, employed in the teaching of the deaf, concerning the establishment of international cooperation in the effort toward providing an access to NIT networks for the entire community of the deaf.

1VL PROJECT INTERNATIONAL VIDEO-LINK APPLICATION OF VARIOUS DATA INPUT, PROCESSING, AND TRANSFER FACILITIES WITHIN THE FRAMEWORK OF THE INTERNATIONAL COMMUNITY OF THE DEAF

The IVL Project of 1995 provides for the application of various video interchange devices for facilitating communication among the deaf of the world.

The establishment of IVL is intended to:

- facilitate communication among increasingly great numbers of deaf people (through the sign language or icons), establish communication links between the deaf of different countries and cultures;
- set up and develop various educational, research and cultural programs within these networks;
- use NIT for training teachers with hearing impairment in the countries with insufficient number of teachers for the deaf;
- assist the hearing parents of deaf children in the learning of appropriate national sign language;
- ensure that the deaf children can communicate with deaf adults using NIT;
- make it possible for the hearing people wishing to become interpreters of the sign language used by the deaf;
- promote the exchange of educational, research and cultural programs both within the community of the deaf and between the community of the deaf and the hearing communities.

Thanks to new information technologies and the multitude of video-data, our societies are creating a new culture on our planet.

The world of the deaf, who communicate with the help of national sign languages as well as graphics and pictography, may find themselves in the vanguard of this new culture.

However, this may only happen if the wealth of new information technologies become available to the deaf and also if the world community realise that human communication is more than mere information exchange.

IVL PROGRAM FOR 1996-97

1. VIDEO-CONFERENCES WITHIN THE INTERNATIONAL COMMUNITY OF THE DEAF

Using special devices already tested by the IVL at previous video-conferences, deaf people of different nationalities (of Moscow, Kiev, Paris, Washington, Jerusalem, Tbilisi, Prague, etc.) analyse and compare in the sign language, without the assistance of a translator, the policies toward education and training pursued in different countries. The video-conferences will work out new lines for the research in the field of education and training.

2. INTERNATIONAL COMMUNICATION OF THE DEAF VIA INTERNET

Within Internet, the Program provides for the establishment of 14 IVL sites; latest news groups between deaf and hearing, Internet access ports for the deaf; training for the deaf experts capable of assisting other deaf people in obtaining access to Internet facilities; an international association intended for research for and design of the optimum communication and education facilities within Internet for the entire world community of the deaf (including overcoming the barriers in approaching the texts, the use of pictorial vocabulary, switch-over to the application of video and operation in the4 direct information exchange mode, etc.).

3. TEACHER-TRAINING OF THE DEAF USING NIT

The IVL Program suggests that the countries wishing to ensure availability of NIT for the deaf people should organise teacher-training for the deaf.

4. A VIDEOTEQUE FOR THE WORLD COMMUNITY OF THE DEAF

The videoteque should contain the entire wealth of the video or other filmed documents created by the deaf or with the participation of the deaf, as well as the main television programs.

It is proposed to film a documentary for both the deaf and the hearing viewers on the specific features of international communication of the deaf. It can be shown in different countries to get the audience acquainted with the subject.

5. TEACHING THE APPLICATION OF NIT TO OF DEAF PRESSMEN

The progress of new information technologies dictates an urgent need to teach the use of new information and communication facilities to the deaf journalists.

IVL offers expert assistance to the countries wishing to start the program of training deaf journalists to use new information technologies.

It is clear that the first stage, that of adaptation to fast-changing novel technologies, particularly as concerns Internet and digital television, should be followed by the second stage, ending in the year 2000.

A deaf person's voice is his/her body.

A deaf person's communication mode is communication via eyesight.

Excluding the deaf from any type of communication is tantamount to infringement upon the right to live.

The NIT's spring into existence in the hearing world dictates the need to revise in full and without any delay the entire range of policies applied in the area of communication and education of the deaf.

The IVL Project is designed to assist in the implementation of these profound transformations. Besides, it is supposed that IVL should promote penetration of the culture of the hearing by the culture of the deaf, and will also facilitate an access for the hearing to the humanitarian values underlying the culture of the deaf.

Annex

Demonstration at the Moscow Congress of communication between two deaf persons of different nationalities without the assistance of an interpreter.

At a video-conference, two deaf persons of different nationalities who had never seen each other before communicated for three minutes from two different geographic sites with the help of video communication facilities.

Discussion

EDUCATION, INFORMATICS AND INTELLECTUAL RIGHTS IN AFRICA

Paulin Mbalanda Kisoka

PRESIDENT OF AFRICAN ASSOCIATION
OF INFORMATICS DEVELOPMENT,
COORDINATOR IN RESEARCH CENTER FOR AREAS
OF LAW, INFORMATICS AND TELECOMMUNICATIONS
OF KINSHASA UNIVERSITY (ZAIRE)

SUMMARY

This presentation is to show that while providing the protection and development of intellectual lights connected with information creative work, one can enable the active participation of Africa in realization of the project introducing new information technologies into educational system, fostering deep creative work in provision of training software. This pioneer role can play the local and regional non-governmental institutions under a UNESCO support.

Similar to fire or gunpowder, a computer ranks among the inventions which left a deep sign in history of human civilizations.

The president F.H.Boigny had declared - and echo of his words were spread anywhere by tom-toms of our state villages - that Africa, being late for industrial revolution train, can ill afford to miss the revolution in informatics. "Because the informatics is a historical possibility for us to respond for all challenges of backwardness." (F.H.Boigny, in Jeune-Afrique Bis, n 10, September 1985, p. VI.)

However none revolution, even technological, and, in particular, informative, lack of organic "magic" ability to cause the new breakthroughs in development, unless it can meet the conditions, promoting its acceptance and mastering in area, where it passes inspection and finds application. The preliminary term concerns about culture and education.

To get rid of "intricacies" and shorten the gap between industrial and developing countries, it is necessary, among other things, to "africanize "software creative work for purposes of training. Specifically, to do this it would require to encourage the developers of such products, promoting their works and protecting their rights [1].

I. INTELLECTUAL RIGHTS IN AFRICA

Most of national legislations, concerning to intellectual and especially author rights are intimated by Western influence and are not marked as efficient in African environment. This can be explained by various reasons. First of all, from political standpoint, the political regimes of last decades did not encourage a creative work, but, on the contrary, they had been establishing the ideological frames in the form of censoring [2].

For this reason the official decisions, by no means, were not incentive for information development and, in particularly, for so-called policy of "equipment purchasing" [3].

From the economical point of view the scientific works did not gain acceptance, since we were not able to provide the due prestigious to authors.

In particular, the originator of software were disappointed by informatics facing to hard competition with imported products and to revelry of piracy.

Finally, from jurisdiction point of view the legislation could not be able to secure the actual protection of authors, supported by administrative and court Bodies.

The violation of intellectual rights are not punished. Moreover, the African jurisdiction is not elaborated in this area at all.

The future of African software creative work, in common, and educational software, in particular, can appear to look uncertain in scope of factors, mentioned above. However, this is a general situation. And still, how to encourage the creative work, which would meet the educational demands of Africa?

II. THE DEVELOPMENT OF EDUCATIONAL INFORMATICS ON THE BASIS OF INTELLECTUAL RIGHTS PROTECTION

The development and protection of intellectual tights in the area of informatics may prove to be the solution of a problem of elimination of a break between the industrial and developing countries while mastering the new information technologies in educational systems. Naturally, the development of rights and the creative work itself may prove to be very useful in many respects:

- owing to financial rewards of authors and upgrading of their scientific authority;
- owing to establishing of a new profession and encouraging the creative work and economical and cultural progress;
- owing to export of African software products and overcoming of their barriers in regard to authors from industrial countries;
- owing to Africa transformation into complete partner in area of information and data exchange at inter-regional level.

Practical terms of realization of such project of development may represent several types of this subject. Apart from establishing governmental and nongovernmental structures, intended to enable the record, acceptance and application of such products; the measures like fairs, national and interregional competitions, the selection from time to time the best products compiling the requirements of special orbs, the awarding of incentive prizes, the granting of scholarships for training or upgrading, may be incorporated over there.

The non-governmental organizations and local Associations can promote advance of educational software products and their authors, attracting an attention to them, advertising their creative work, conducting the educational work. Specifically, they would select the useful products and recommend them to school authorities in due order.

The educational activity of those organizations could, for example, consist of explanation to African people of the fact that human rights are concerned about not only political rights. Really, the violation of intellectual rights are also the violation of human rights. Their activity in this specific area could coincide with the activity of traditional unions of human rights defenders, being expressed as acts of unmasking, protection and education.

The issue of informatics and ethic must also be in focus of attention of those organization. Naturally, the introducing a computer to school must be followed by definite educational efforts from a child's side and, therefore, from a teacher's side.

All these actions constitute an integral art of activity, that African Association promotes for the development of informatics in Zaire, realizing several projects, one of which is called "Informatics for everyone", lies in the fact that women and children must be teached for mastering a computer.

UNESCO, being involved in author's rights, could play a useful role in supporting the activity of those Associations through offering the necessary strategies and mechanisms of international cooperation. Advocating for education in the interests of peace and for elimination of crying inequality among people, provisions should be made today for the idea of educations, going beyond the scope of structural cooperation - education with human face.

CONCLUSION

The development and protection of intellectual rights, connected with educational and informative creative work is an effective way to shorten, if only a bit, the gaps between industrial and developing countries.

The intellectual rights - the source of progress. The progress, being generated by introducing the new information technologies in African educational systems, is capable to provide for the continent a beneficial export of its richest information potential, to release its talents from a intricacy of "marginality".

Thank you for your attention, I am going to deliver some recommendations to the speaker of our Commission.

The appeal of Mr. NSAMBI BOLALU at Moscow Congress, 03.07.1996.

Mr. President,
Dear colleagues,
I asked for a floor to express the apologies of my compatriot Mr. Paulin Mbalanda Kisoka from Zaïre, who could not come to Moscow because of family problems, arised unexpectedly. Mr. Paulin Mbalanda entrusted me to deliver his address to Congress, which I am trying to bring to all of you. This address from distant Africa is devoted to education, informatics and intellectual rights in Africa. Here it is.

THE ROLE OF COMPUTERS IN EDUCATION: ACHIEVEMENT AND COMPREHENSION

José Armando Valente
NÚCLEO DE INFORMÁTICA APLICADA À EDUCAÇÃO
UNIVERSIDADE ESTADUAL DE CAMPINAS - NIED /UNICAMP
(BRAZIL)

INTRODUCTION

In most cases education processes are restricted to asking students to do various activities, which they can, or cannot, do successfully. However, the fact that they may be able to accomplish these activities does not mean that these students necessarily comprehend what they have done.

The distinction between achievement with success (savoir faire) and the comprehension of what is achieved is presented by Piaget (1974). He says that a child is able to do complex actions with success without necessarily comprehending all the concepts involved in the activity. The passage from the level of achievement to the level of comprehension is done thanks to the grasp of consciousness. This passage requires the transformation of action schemes into notions and operations (Piaget, 1976).

The uses of computers in education can fall into the same path. With the computer, the student can do lots of activities and achieve them successfully. However, depending on the type of software used. and the teacher's involvement in the computer activity, the student may, or may not, understand what he has accomplished. This is the case when the student uses a tutorial or many multimedia software. The student's action can be reduced to turning the next page of the lesson or choosing among several options presented by the software.

However, when the student programs the computer to solve a particular task, he engages in an activity that demands different actions which can create the conditions for comprehending what he is doing. The process of programming can be seen as a cycle consisting of description-execution-reflection-debugging-description (Valente, 1994; Valente, 1995a).

In the cycle "description-execution-reflection-debugging-description", debugging constitutes a unique opportunity for the student to construct hers/his knowledge and to understand what s/he is doing. With the help of the teacher, the cycle can be used by the teacher and the student to understand about how, when and what makes the construction of knowledge possible; it makes possible a discussion about "learning about learning" since the student in the process of looking for information is exercising hers/his learning skills; and it raises questions about "thinking about thinking" since the student can analyze hers/his program in terms of effectiveness of hers/his ideas, strategies and problem solving style.

In this paper I discuss the different types of software used in education and I argue that the programming activity is an opportunity to engage in the passage from achievement to comprehension. Programming involves certain actions which are essential for the development of important skills which are often not present in the educational process today nor in many types of educational software. This discussion allows us to understand the role of the computer in education, and the role of the teacher and students in the computer based learning environment. Also, there are several outcomes from this discussion that can help us to set up more effective teacher training programs and educational policies involving computers.

PIAGET'S VIEW OF SAVOIR FAIRE AND COMPREHENSION

In 1974 Piaget published two books, *"La Prise de Conscience"* - translated into English as *"The Grasp of Consciousness"* (Piaget, 1976) - and *"Réussir et Comprendre"* (Piaget, 1974), reporting the process by which children and adolescents come to develop what he called "conceptualized comprehension" of concepts involved in a series of tasks he asked his subjects to perform.

In his studies Piaget observed that children can use complex actions to reach premature success which represents all the characteristics of a *savoir faire*. The child can do a particular task but does not comprehend how it was done nor is aware of the concepts used to achieve the task. Piaget observed also that the passage from this practical form of knowledge to thinking is done through the grasp of consciousness which does not constitute a kind of enlightenment but a level of conceptualization. This level of thinking is reached thanks to a process of transformation of action schemes in notions and in operations.

Thus, through a series of more and more complex concept coordinations the child can move from the level of premature success to a level of conceptualized comprehension.

Piaget showed that the passage from premature success to conceptualization is done in three stages: in the first stage the child neglects all the elements involved in the task; in the second stage the child coordinates some elements; and in the third the child coordinates all the elements involved in the task. He showed this using several tasks such as constructions of objects with a deck of cards, tipping over dominos arranged in a line, playing with scales, etc. The tipping over dominos is a good example to help us to understand these three different stages.

The child is asked to arrange dominos in a line such as if we tip over the first domino, this will tip the following and successively will tip the next until all the dominos in the line fall over. The task is divided into two parts. In the first part the child plays with two dominos trying to predict the interval between the dominos that will make the first domino knock down the second one. Then the child is asked to arrange all the dominos in a line, connecting two points A and B. After the child has constructed the line, the child is asked to predict which dominos will fall and which will not, and why. Then, he is asked to tip the first domino and observe what happens to the line of dominos. In the second part of the task the child is asked to connect the points A and B using different trajectories. The first is a simple diagonal and for the second trajectory, an obstacle, a lake or a mountain, is placed between points A and B.

Children about 5 years of age can arrange the dominos in a line and accomplish the first part of the task with success. However, when playing with the two dominos these children cannot understand that the distance between the dominos is an important element in the construction of the sequence of dominos. They think that what makes the subsequent dominos fall is how hard they push the first domino or that the dominos need to be closer to each other, but they cannot make explicit how much the distance between dominos must be. In this sense, these children can reach the objective of the task but they are not aware of the role of the distance between dominos or other concepts involved in the task. Thus. these children's performance indicated that they are considered to be in the first stage.

The next stage is reached when the child is around 6 years old. This stage is characterized by the fact that the child starts to understand and can articulate the idea that the distance between dominos must be less that the height of the dominos. However, they cannot organize the dominos so they can avoid the obstacle or to arrange the dominos in a diagonal line. Their argument is that it is impossible for the dominos to be arranged according to a circular or diagonal line.

Thus, these children can coordinate the distance element present in the sequence of dominos but cannot coordinate the direction of the dominos. The passage from stage one to stage two happens because the child, in the process of constructing the sequence of dominos, observes that if the dominos are too far apart, one cannot lean on the other or the first domino cannot "touch" the other one. In this situation the child corrects the distance between the dominos, and becomes aware that the distance between dominos has to be such that one has to be able to lean on the other. However, for these children the dominos have to be parallel to each other and, consequently, the sequence of dominos can only be in a straight line. The dominos cannot be arranged one a little to the side of the other so that the sequence can be in the form of a diagonal or a circular line.

Children from the third stage can coordinate all the elements involved in the task: distance, direction and weight of the domino. They understand that as long as each domino falls on the subsequent one the sequence of dominos will fall. They can arrange the dominos so they will fall in a circular or diagonal line. Also they understand that the closer the distance between the dominos, the faster the sequence will fall; and if the dominos are very light (made of plastic) the closer they have to be so a domino will "lean" on the next instead of just touching the next domino.

Besides the sequence of stages, Piaget observed that, first, it is not the object that leads the child to the comprehension stage. It is not the case that a child who comprehends how the dominos works will comprehend how to make a castle using a deck of cards. For each situation the child has to transform the action schemes into notions and operations that are involved in a particular task. Second, Piaget noticed that comprehension is the fruit of the quality of the interaction between the learner and the object. If the child has a chance to play with the objects, to reflect upon the results obtained and to be challenged with new situations, the greater are hers/his chances to be aware of the concepts involved and, thus, to reach the level of conceptualized comprehension.

These last two observations are fundamental to understanding the relationship between the learner and the computer in a computer based-learning environment. It is not the software that determines whether the learner will be able to reach the stage of comprehension of the concepts involved in the task but the quality of the interaction between the learner and the software. The analysis of the interactions which take place between the learner and various educational software will help us to understand the role of the computer.

ANALYSIS OF THE DIFFERENT EDUCATIONAL SOFTWARE

Any attempt to classify the different uses of computers in education is problematic and can result in a very simplistic view of what has been produced in this area. However, it can be an interesting exercise and can help us to understand the role of the computer and how it can be effective in the process of knowledge construction.

Computers have been used to teach about computers — computer literacy, and to teach practically any subject — teaching through the computer. In computer literacy the students use the computer to learn about programming, about computer principles and about the implications of computer usage in society. Although the majority of computers in education projects are about computer literacy, certainly this is not the kind of applications we want to discuss here.

Teaching through the computer means that the student uses the computer to gain knowledge in a particular area. However, the pedagogical approach used can fall in one of two groups: software that have the characteristics necessary for the child !o comprehend the task being developed and software that helps the child to do things but have very few characteristics to help the process of comprehending what is being done. Among the software that help the comprehending process is computer programming languages and multimedia authoring systems. In the other group we have the tutorials, drill-and-practice, word processing and the use of multimedia.

Tutorials

A tutorial is a software in which the information is organized according to a particular pedagogical sequence and this information is presented to the learner following this sequence or the learner can choose the information s/he wants to see. In the first situation, the software has the control over the teaching situation and what can be presented to the learner: the learner can change items by simply pushing the ENTER key or the software alters the sequence according to the answers given by the learner. In the other situation, the learner has the control and can choose what s/he wants. In general, these user controlled software are organized in a hypermedia fashion and the learner can "navigate" between items of information.

In both cases, the information available to the learner was previously defined and organized. The learner is restricted to this information and the computer assumes the role of a teaching machine. The interaction between the learner and the computer consists of reading the screen or listening to the information give, advancing through the material by pressing ENTER key, choosing information with the mouse, and/or answering questions by typing on the keyboard. By observing this behavior we see that the learner is doing things but we do not have any clue that s/he is understanding what s/he is doing. S/he may be processing all the information given but we do not have the means to certify that this is the case. One way of having access to this knowledge processing is by presenting problem situations in which the learner has to use the information given. Some software try to do this but, in general, the problem presented verifies that the learner memorized the information given, or requires a direct application of the information given in a very restricted domain. An open ended problem, that would allow for more that one type of solution would show the level of concept comprehension, is very difficult for the computer to correct. This type of evaluation is left to the teacher. Most tutorials are not developed with that intention. Unfortunately the teacher is often unavailable to follow what the student is thinking while using a tutorial.

Thus, I classify the tutorials as software that allow the student to achieve a certain task such as go through a lesson or acquire a piece of information but these software have very few features that can contribute to the comprehension process.

Programming

When the student programs the computer, the computer can be seen as a tool with which the student can solve problems. I argue that the program produced has several features that allow the learner to accomplish a particular task and to comprehend what s/he has done. Although I am going to analyze the programming activity through the use of the Logo language and I concentrate this analysis on the graphics aspect of Logo, as was mentioned in another study (Valente, 1994) this analysis transcends Logo and can be used to explain other ways of using the computer in education.

In the Logo graphics environment, as the student is solving a problem, hers/his interaction with the computer is mediated by the Logo computer language or, more precisely, by Logo procedures This interaction is an activity that begins with an initial idea the student develops about how to solve the problem. This idea is passed to the computer (or the Turtle) in terms of Logo commands. Thus, the student is acting upon the object "computer", however, this action is a description of the problem solution through the Logo computer language (Logo procedures). The computer, then, **executes** these procedures. The Turtle "walks through" the procedure commands and presents a result in terms of a picture on the screen. The student looks at this picture being constructed and to the final goal and s/he can **reflect** upon them. This reflective activity can produce several levels of abstraction, which according to Piaget (1977) will affect the student's intellectual structure. The student's reflective activity can lead to one of two alternative actions: doing nothing, when the student's original ideas correspond to the result presented by the computer, then the problem is solved; or **debugging**, when the result is different from what the student intended. And the debugging can be either in terms of concepts in the subject area (the student does not know about angles, for example) or about some convention in the Logo language, or about strategies (the student does not know how to apply a particular concept).

The debugging activity is facilitated by the existence of the computer program. This program is the student's description of hers/his ideas in terms of a formal, precise and simple language. The Logo graphics language is easy to assimilate and the commands are similar to the terms we use in everyday life. This minimizes the arbitrariness of the conventions and the difficulty in translating ideas into code.

These characteristics are not found in any other type of activity we do. That is, as the student acts on the world he receives, as a subproduct, the description of the ideas that support hers/his actions. Also there is a direct correspondence between each command and the computer's action. All these aspects available in the programming process facilitate the analyzes of the computer program so the student can find hers/his bug. The process of finding and correcting the bug constitutes a unique opportunity for the student to learn about particular concepts involved in the problem solution or about problem solving strategies. Also the student can use hers/his program to relate to hers/his thinking at the meta-level. S/he can analyze hers/his program in terms of effectiveness of hers/his ideas, strategies and problems solving style. This way the student begins to think about hers/his own thinking (reflexive abstraction).

The program the student produces is a description of the hers/his thinking process. This program contains important information about the child's knowledge and strategies and, thus, the student's comprehension of the concepts involved in the task. The execution of this program can be seen as the execution of the learner's thinking. The computer execution gives us two important ingredients for the comprehension process. First, the computer feedback is faithful. Since the computer does not add any new information or knowledge to the student's program, any mistake found in the result of running the program is the product of the student's own thinking. This faithful feedback is extremely important in order for the learner to become aware of what s/he knows, and the kind of information s/he needs to get in order to debug hers/his ideas. Second, the computer feedback is immediate. After the student pushes the ENTER key s/he has the results being constructed step by step. The student can confront hers/his original ideas and when the result obtained on the screen. This comparison constitutes the first step in the reflective and in the grasp of consciousness processes. These processes can be enhanced by the program which is a formal description of the student's thought. If we save all the different versions of the program produced by the student we can follow the process by which the student developed the concepts involved in the program.

Thus, if we ask the question "why do we want computers in education?" the answer is that we want to explore the computer features which contribute to the conceptualization process. These features include the expression of the student's thinking in a formal and precise language, the execution of the student's thinking, and results which are faithful and immediate. These characteristics present in the programming activities help the student to reach the conceptualized comprehension stage because the student can reflect on hers/his actions and ideas. This reflection is the mechanism by which the student becomes conscious of hers/his knowledge and, thus, can transform hers/his mental schemes into more complex notions and operations.

However, this process does not happen by just placing a student in front of a computer. The interaction student-computer needs to be mediated by a professional who knows about the Logo ideas, from the computational, pedagogical and psychological points of view. This is the role of the Logo teacher. Also, the student, as a social being, is inserted in social environment that is constituted, more locally, by hers/his pears, and more globally by hers/his parents, friends or even hers/his community. S/he can use all these social elements as sources of ideas, knowledge or problems to be solved through the use of the computer.

Word processing

When a student is writing a text using a word processor hers/his interaction with the computer is mediated by the natural language (mother language) and the commands of the word processor to format the text. Many word processors are simple to use and facilitate the written expression of our thoughts. However, the execution part is very handicapped. The word processor only can execute the format aspect of the text or some aspects of writing style, but they can not yet execute the content of the text and to present feedback in terms of whether the content represents what we mean. Since the computer can only present the result of the format execution, the student can only reflect upon the original ideas about the format in comparison to the result presented. The student can read the text but since the computer cannot execute the text content there is no content result to be compared with the original content idea. Thus, the reflective and debugging activities are possible only in terms of the text format. In order to debug the content, the text needs to be read by another person who can interpret it and provide the student with appropriate feedback in terms of the text content.

When using word processor, reflection on and debugging of the text content is not facilitated by the computer. The computer does not provide the necessary information for the student to be aware of hers/his knowledge level and, thus, to reach more complex level of conceptualized comprehension. In this sense, I classify word processors as software that help the student to accomplish tasks but not to comprehend them. The comprehension only can be accomplished by having someone read the text and provide the feedback with which the student can become aware of hers/his performance.

Certainly, by having the text in the computer it is much easier to debug it. The text does not need to be rewritten all the time and this facility can establish a different relationship between the student and the text. However, the fact that the computer cannot execute the text content is a major handicap. We do not have the faithful feedback as we get with programming. The feedback provided by another reader may or may not correspond to the real quality of the text. Without faithful information it is much harder to reach more complex levels of conceptualized comprehension.

Multimedia

Multimedia can be explored educationally in two different manners: use of ready made multimedia software and development of multimedia, by the student, through multimedia authoring systems.

When using a multimedia the student is selecting options that are available in the software. Thus, s/he is not describing hers/his thinking but is deciding among several possibilities offered by the software. Once a selection is done, the computer presents the information available and the student can reflect upon it. Based upon this analysis, the student can select other options. This series of selections and going from one topic to the other, constitutes the ideas of navigating in the software.

It is true that the multimedia software are becoming very interesting, creative and are exploring an incredible number of possibilities. It is possible for the users to navigate in a broad spectrum of topics as well as to go in depth in these topics. However, the student is always restricted to what the software has available. If a particular software does not have what we want, we have to purchase another software. Also this idea of navigating can keep the student very busy for a long period of time. However, very little may be accomplished in terms of comprehension and transformation of the information visited into knowledge that can be applied in a meaningful way. In this sense I classify the use of multimedia in the category of software that helps the student to acquire information, but not to comprehend what s/he has acquired. In the process of navigating the student can come in contact with an incredible number of different ideas. But if this information is not put into use, there is no way we can be sure that this information will transform or enhance new ways of thinking about a particular subject.

When the student is developing a multimedia software through the use of an authoring multimedia system s/he is constructing a sequence of information presented through different media. The student has to select information from the literature or from other software, and may have to program specific items to be included in the multimedia being developed. Once these items are included in the multimedia the student can reflect upon and debug them in terms of the quality, depth and meaning of the information made available in hers/his software. Constructing multimedia provides a chance to pull together information in a coherent project, making sense of information and critiquing it.

In this sense, the cycle description-execution-reflection-debugging established has particular features. The level of description and execution are not the same as the in the programming activity. Authoring systems do not require the student to describe everything s/he is thinking while selecting a particular piece of information or even which media to present this information. Also the multimedia authoring system does not register the process the student uses to set up the multimedia software. Thus, the computer executes the sequence of information and does not execute the information itself. In this sense, multimedia execution is very similar to the execution in the word processor.

The cycle is in terms of getting the multimedia to work. In terms of the content, it can be rich or poor depending on how much the student comprehend about the information present in hers/his software. She/he may know and comprehend a lot if the subject was worked out. May know very little if the subject was just copied from one source to the software being developed.

Since the multimedia authoring systems do not register the thinking process that goes along with the construction of the multimedia, it is necessary to complement the product being construct with some kind of report that describe part of this process. For example, a diary describing what was done, what was discussed in terms of items selected, or what was thought about the items or the strategies in organizing the information as shown in the multimedia constructed. This report is produced separate from the multimedia and constitutes into a task that adds very little to the real construction of the multimedia. However, it is not impossible to implement in the authoring system a facility to help the student describe the construction process.

The analysis of these different ways of using the computer shows that in order to be able to construct knowledge and to comprehend what we are doing, computer software needs to have certain characteristics to facilitate the description, reflection and debugging activities. Programming languages seem to have most of these characteristics. The other educational software such as tutorials, use and construction of multimedia, and word processor the computer does not execute the student's thinking process and therefore the computer feedback is not helpful for the student to comprehend what she/he has done. These findings have several implication in terms of setting up policies for implementing computers in education.

TRANSFORMING EDUCATION

The use of computers to help students to accomplish tasks without comprehending what they are doing is a mere informatization of the teaching process we have in our schools today. The possibility that the computer offers as a tool to help the students to learn, to construct knowledge and to comprehend what they do constitutes a true revolution of the learning process and a chance to transform schools.

Traditional teaching and the informatization of traditional teaching practice are based upon the transmission of information. In this case, the teacher, as well as the computer, are owners of knowledge and assume that students are empty vases to be filled. The result of this teaching approach is a passive student, without capacity to critique and with a vision of the world according to what was transmitted to her/him. This student will have very little chance to survive in the knowledge society we are about to enter. In fact, traditional teaching or the informatization of it produces students that are obsolete.

The knowledge society requires creative individuals and with the capability to critique, to think, to learn about learning, to work in group and to know about hers/his own potentials. This individual will need to have a general vision about different ecological and social problems that are the concern of today's society as well as deep knowledge in specific domains. This requires an individual who is attentive and aware about the changes happening in our society and who has the capability to constantly improve and debug hers/his ideas and actions.

Certainly, this new attitude is the fruit of an educational process whose objective is the creation of learning environments in which students can experience and develop these capabilities. This knowledge is not possible to be transmitted but it has to be constructed and developed by the students. This implies that the schools we know today must be transformed. This transformation is much deeper than simply installing computer as a new educational resource.

Computers must be inserted in a learning environment that allows the construction of knowledge, comprehension of what the student has done and the development of capabilities that are necessary to function in the knowledge society. Learning a particular subject must be the product of a knowledge constructing process, done by the student through the development of projects using the computer as a source of information to solve problems that are significative to the student.

Through the process of solving these problems the student can learn about how to get new information necessary to be incorporate in the problems solution (to learn about how to learn); to be critical regarding the results obtained; to develop debugging strategies and to understand that debugging is the engine that drives learning. In this way students can acquire the capabilities and values from the knowledge society because she/he experience these capabilities rather than because they are transmitted by the teacher.

Teachers also need to be trained to assume the role of the facilitator of the student's knowledge construction rather than the transmitter of information to the student. For this, teachers need to be trained in terms of computer technology, educational software, as well as how to integrate this resource into the respective classroom activities. It must be clear to the teacher when and how to use the computer as a tool to stimulate learning. This type of knowledge needs to be constructed by the teachers and it occurs as they use the computer with their students, with the support from experts who can help the teacher to become more effective in their role of using the computer with their classroom. Through this support teachers can improve their capabilities as facilitators of knowledge construction and, gradually, to leave the role of information deliverer to become the facilitator of student's knowledge construction.

The transformation of schools is becoming more and more necessary. The knowledge society we are about to enter will demand that this happens. It is a difficult process. However, if the computer enters the school to become a device to turn pages of a book electronically or a resource to fix curriculum content, we will be running the risk of computerizing a school that is already obsolete, fossilizing it definitively.

The same transformation required in schools today is also require in training process outside the schools, for example in industries. Comprehension is particularly necessary if we want the person completely involved in what s/he is doing: a level of involvement which is required in a modem organization lean factory.

Industries are going to a major transformation, from the traditional mass production approach to a lean production (Womack, Jones & Roos, 1990). The lean approach produces only what the consumers want, the defects are identified during the production process rather than at the end of the assembly line, and production processes are constantly improved in order to eliminate excesses of time, labor, materials and supervisors. However, it demands several changes that have been hard to incorporate into our society. For example, production will need fewer, but more highly skilled workers (Mazzone, 1993).

The same educational transformation that is needed in the schools is also necessary in the job training programs. The companies, like the schools, can benefit from a training program based on the construction of knowledge and comprehension of what ones does. In this sense, here is a need for new and more adequate learning tools to identify problems and absorb technologies. The new production processes demanded profound changes in work habits and in the policies and behavior of the company itself. There is a need for learning methods that could motivate comprehension and real assimilation of know-how by employees on all levels.

CONCLUSION

When we ask educators about why we should have computers in education, always we get the answer that the computer can help or that the computer can facilitate education. The idea that the computer should always facilitate comes from a generalization of the fact that the computer entered our lives to facilitate. The computer made possible cash machines, computers are inside every automated device such as microwaves, video recorders, cars, etc... These are examples in which the existence of the computer made everything much easier or made available a facility that we did not have before the computer. Thus the same thing should happen to education. The computer should facilitate education, making it much easier for the student to learn, for the teacher to teach, or to organize the administrative part of education.

However, when I analyzed the different uses of computers in education, the conclusion was that the uses that are very similar to traditional teaching practices are the least effective ways of using computers as a tool to promote learning or comprehension. I showed that the computer can help the conceptualization process and the development of capabilities that are very important in the knowledge society if it is used as a programming device. In this sense the computer is a complicator. The student has to describe to the computer all the steps in the process of problem solving, has to do this through a computer language and if the results do not correspond to what was desired, the student has to get the information, incorporate that into the program and repeat the cycle of describing, executing, reflecting and debugging hers/his ideas. This is hard work. The computer is not facilitating this task in the sense of making problem solving easier. The computer is not giving the solution of the problem on a silver plate as we would expect if we had a device that would facilitate our life as it does in the cash machines.

Throughout the article I argue in favor of comprehension because it allow the student to be better prepare for the knowledge society. However, there is another reason for comprehension that is related more to the affective aspect. The effort of creating computer-based learning environments for different populations such as students from regular schools (Valente, 1993) and from special education (Valente, 1991), street kids (Valente, 1995b), teachers (Valente, 1996), workers from the lean factory (Valente, forthcoming) has shown that when given the opportunity to comprehend what they do all these individuals experience the feeling of **empowerment.** This is the sensation that they are capable of producing something that they thought was impossible. Moreover, it is a product that they not only have accomplished but they comprehend. They can talk about what they have done and they can show it to other people. It is a product of their minds.

Piaget in the *"Reussir et Comprendre"* book (Piaget, 1974) talks about the same idea in terms of the **direction to the future.** What motivates an individual to comprehend a task is the desire to achieve, in the future, a result that is predicted actually. However, the process to look for the reasons for one assertion or a phenomenon leads to solutions that will create new problems with new solutions and so forth. This direction to the future oscillates between a determination from the past and openings to unpredictable novelties. But the individual knows that through hers/his reasoning s/he will be able to reach a level of conceptualized comprehension. This is reached through reasoning and not through guessing or discovering.

This sense of empowerment and trust on our own mental capabilities gives us the incentive to keep improving our mental capacities and to debug our action and ideas. We know that we can reach higher levels of comprehension if we keep thinking about what we do and the way we think. It seems that this feeling of empowerment is missing in our schools. We should do everything possible to bring back empowerment to the learning environment and to have the direction to the future. If we think about transforming the schools we should aim to have an environment that can provide the learners with the experience of the empowerment. After that, it is just a matter of time and a question of keeping the environment rich, challenging and stimulating so that any individual will learn about practically anything. This should be the main objective of the school that is compatible with the knowledge society.

NEW APPROACHES NEEDED TO TEACHING, LEARNING AND THE USE OF INFORMATION AND COMMUNICATION TECHNOLOGIES IN EDUCATION [1]

Tjeerd Plomp [2]
Alfons ten Brummelhuis
Willem J. Pelgrum

UNIVERSITY OF TWENTE, ENSCHEDE
(THE NETHERLANDS)

WHAT IS THE DIRECTION FOR THE FUTURE OF LEARNING?

Computers, especially when they are linked in networks, have the potential to change every day classroom practice dramatically. The impact of the use of information and communication technology (ICT) in education will not be limited to the actors involved in the learning process (teachers and students), but will also change the institutional infrastructure, relations and patterns of behavior within the education system, and even the content of education. For a good understanding of these educational changes if is necessary to look at the transformation our society (in the industrialized countries) is undergoing.

In fact, education is reacting to the emergence of the information society. Traditionally, schools provided the settings where individuals were being prepared for the industrial society. In this society the focus was on 'making things', on industrial production. Today's educational system faces the challenge to prepare individuals for the information society in which one of the most important aims is to handle information. Such a shift in focus can be seen as a new stage of our society, characterized by a new predominant paradigm. A simple overview of successive stages of development of our society is depicted in figure 1.

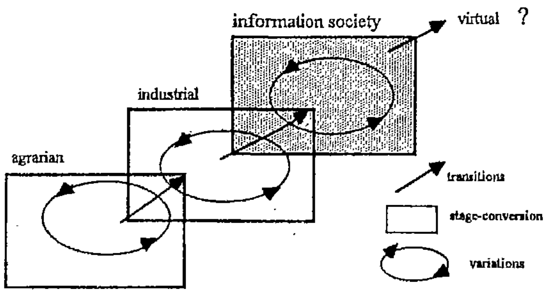

Figure 1. Successive stages in society
(Based on Van Dongen, 1996, unpublished)

The stages are in itself not stable: in each stage, changes and developments are taking place continuously, but these changes tend to stay within the boundaries of the dominant paradigm and the reigning technology. Problems faced are basically variations of common practice, while the order of things is kept in place. After a period of time, successive variations are getting less effect and tension grows until the next stage is apparent and a transition takes place. The conversion to a next stage is influenced by the availability of a catalyst of some kind (money, new energy sources, technological developments such as computers, networks, etc.).

In general terms the mission of the education system is to provide balanced, personal, social, and vocational education, facilitating personal growth and development, citizenship, and preparation for a profession. Quality of education can be defined as the amount to which education is capable to realize these goals. Beside the challenge of preparing individuals for the information era, the education system is also facing other challenges:

- a contribution is expected from education to the solution of social, cultural and economical problems of society. Education can no longer stay aside from all the problems of society: isolation, ethnic integration, juvenile delinquency, non-labor, etc., etc. There is massive evidence that the level of someone's education correlates directly to the opportunities someone has in society (OECD reports 1988 - 1994).
- people want education to be individualized and flexible, suited to their specific needs. Growing individualization in and diversification of society calls for specific approaches in education. Standardized methods and classroom approaches will no longer be sufficient for individual needs.
- life-long learning and new demands for learning. The 1994 report of the SCP (the Dutch national office of social and cultural studies) states that the growing number of people that is participating in education is the main issue to be addressed by the educational community. The guarantee for open and equal access to education for everybody is under the current circumstances becoming almost unaffordable.

Tjeerd Plomp, Dept. of Curriculum, was chair of the International steering committee of the IEA CompEd study and is since 1990 chair of IEA. He is also the chair of COMMITT, the Committee on Multimedia in Teacher Training, an advisory committee to the Dutch Minister of Education, Culture and Science. Dr. Alfons ten Brummelhuis is working at OCTO, the Center of Applied Research on Education of the Faculty of Educational Science and Technology. He is secretary of COMMITT. His Ph.D. research was based on CompEd data. Dr. Willem J. Pelgrum, also at OCTO, was the international coordinator of the IEA CompEd study.*

It can be concluded that the near future provides all kinds of challenges and opportunities for the educational system in our society. Managing large amounts of information, developing learning strategies to facilitate effective learning, and assuring that all citizens are skillful in assessing, selecting, and dealing with information are of critical importance. It is assumed that new balance is needed between teacher oriented arrangements of the learning process and student oriented arrangements, within which much more emphasis should be given to. the latter. ICT provides a means to instrument these revolutionary changes called for by the evolutionary transitions in society. ICT as a tool to support the learning process holds a promise to new solutions for the challenges that education is facing.

DIFFERENT SCOPES FOR THE USE OF ICT IN EDUCATION

The use of ICT as part of the learning process can be subdivided in three different forms: as *object*, as *aspect*, or as *medium* (Ministry of Education, 1992). In addition, ICT is often used as a tool for organization and management in schools. In the latter case ICT is not integrated in the actual learning process but provides support to it at classroom level or at school level (an example of an ICT application for organization and management purposes is a student monitoring system).

The use of ICT in education as *object* refers to learning about information technology and is mostly organized in a specific course such as 'computer education' or 'informatics'. As an object, ICT has been implemented broadly in the curricula of schools, especially in secondary education. Following the 'ICT-as-object-courses', students familiarize themselves with the most important ins and outs of information technology as a dominant phenomenon in society. Its educational aim is prevention of computer illiteracy. At present, education is quite good at this. But we have to take Walker's (1986) warning seriously, namely that the easiest way to meet the challenge of technological revolution is to create and implement a new subject, so the existing subjects don't have to change.

ICT as *aspect* refers to specific applications of ICT in education as used in industry and professional practice. Such use in education is found for the most part in vocational education, for example in the training for. computer aided design and manufacturing, and computer mediated accounting. Vocational training in these areas is unthinkable without ICT integrated in it. ICT as an aspect also appears outside the vocational territory, in subjects that are no longer teachable without the technology. For example, in general education carrying out experiments in science education, or accounting as part of economics. For that reason ICT has become an obligatory part of the general exams in science and economics in general secondary education in the Netherlands. The educational aim of ICT as aspect in education is job preparation.

Today, ICT as object and as aspect are firmly embedded in our educational practice.

A third form of use is ICT as *medium* for teaching and learning. This refers to ICT as a tool for teaching and learning itself, the medium through which teachers can teach and learners can learn. ICT as medium appears in many different forms, such as in drill and practice exercises, in simulations, in tutorials, in individual learning systems (ILS), in educational networks, in hypermedia programs, in tests-generating systems, etc. We speak of ICT as medium whenever ICT is used to support the teaching and learning process and not specifically its content (which is the case when ICT is used as object of learning). Current practices of actual use of ICT as medium are few, though there is a growing interest in applications of ICT as a medium.

In this paper we will focus on *the use of ICT as a medium* in learning and teaching.

ICT AS A MEDIUM TO ENHANCE THE LEARNING PROCESS

For a good understanding of the potentials of ICT for teaching and learning, it is important to have a closer look at the learning process. Figure 2 provides a general overview of aspects influencing the learning process. The learning process is represented as a field in which four forces operate. The horizontal dimension represents the relation between the actors in the learning process: the *teacher* and *learner*. The vertical dimension represents the *learning infrastructure*, consisting of *content*, and *teaching & learning materials*. The learning process takes place at the cross section of these four forces. The contribution at the level of school organization and management on the arrangement of the learning process (e.g. by providing a student monitoring system) is represented by the outer circle.

The figure illustrates the view that a learning process is the result of both structural conditions derived from the learning infrastructure and personal characteristics of the actors involved, and their interaction. Changing just one of the driving forces, may lead to tensions, but not necessarily to substantial changes and improvement of the learning process. The introduction of ICT in the learning process, as medium for learning, obviously changes the learning infrastructure in terms of materials and technical infrastructure. But, only in conjunction with changes in the roles of the teacher and the student, and with changes in the organization of the content, it is possible to make use of the potentials ICT holds for enhancing the learning process.

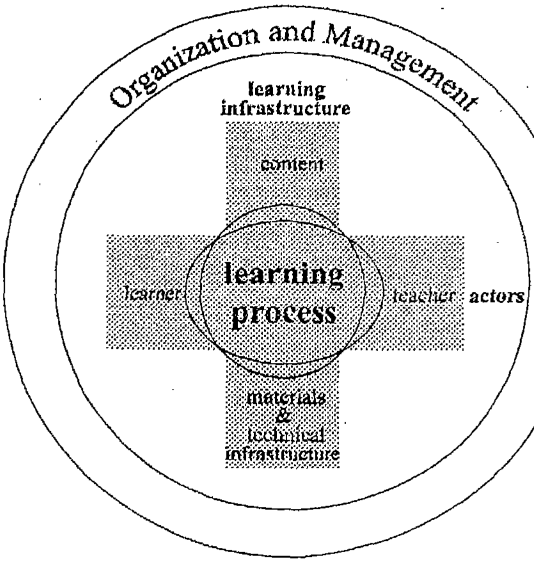

Figure 2. The infrastructure and actors of the learning process

In addition to the dimensions of the learning process at school level mentioned above, changes in the learning process have to be supported from public administration as well. It is hard to imagine how ICT as medium can be implemented in a way that it has impact on the role of the teacher, without proper policy measures at the level of the national government. Installing computers and software for an integrated learning system for instance, is one step and a relatively simple one compared to what has to be done for a structural change in the role of the teacher (needs consent by teachers, teachers unions, management, government), a commitment to more student oriented learning (needs organizational measurements to regulate the use of the schools resources), and a focus on learning which is often labeled by 'constructive learning'. Learning is, in this view, perceived as an active, constructive, goal oriented, and situated process.

THE LEARNING PROCESS IN MORE DETAIL

Adjusting education to societal needs of the future (the information society) means that schools have to enable learners to be continuously active in the sense of lifelong learning. Stimulating and supporting this process of continuous learning implies the elaboration of suitable learning processes in which the learner learns how to become more or less an architect of his/her own learning process. This means that learners have to be more involved in the arrangement of their own learning process. However, learning always refers to a process in which the learner needs support in terms of well-adapted subject matter content, organization of learning activities by a teacher, adequate materials and technical infrastructure. It is assumed that ICT has the potentials to enhance such an approach of learning that prepares for the information society.

The use of ICT as part of the learning infrastructure and its relation to the role of the actors in the learning process (learner and teacher), can be clarified by looking in more detail to the characteristics of the teaching and learning process. Table 1 provides an overview of the activities that can be distinguished in relation to the learning processes (Simons & Zuylen, 1995). The set of activities refers to three main types of activities in the learning process: preparation, executing instruction, and regulation.

In a traditional arrangement of the learning process most of the activities listed in table 1 are under control of the teacher. If a learning process is more student oriented it means in operational terms of the activities listed in table 1 that the student becomes more responsible for (some of the) activities which are completely under control of the teacher in the teacher oriented learning process. It is assumed that a shift from teacher oriented arrangements of the learning process towards more student oriented arrangements can be facilitated by ICT. However, until now these potentials of ICT are hardly implemented. More student oriented arranged learning processes are still rare, and most of the current ICT-applications are used as far as they facilitate the teacher oriented arrangements of the learning process. Applications of ICT are adapted to the existing teaching routines; the beliefs and attitudes of teachers towards their teaching practices did not change, and basically the teaching and learning process itself did not change.

For the development of effective strategies to use ICT to enhance learning and teaching, it is important that we realize that the present use of ICT is just a *substitution* of the current teaching and learning activities. This substitution use can be seen as the first out of three phases through which the implementation of new technologies diffuses in general and therefore also in education (Itzkan, 1994).

Table 1

Activities in the learning process (Simons and Zuylen, 1995)

I. PREPARATORY ACTIVITIES
cognitive
1. orientation towards learning goals and strategies
2. clarification of learning goals
3. choosing and defining subgoals
4. choosing and defining learning strategies
5. mobilizing prerequisite knowledge
affective
6. making students curious
7. challenging yourself
8. generating interest
9. focusing attention
10. clarification relevance
11. getting under way
II. EXECUTING INSTRUCTION
12. absorb knowledge, practicing skills
13. reflecting
14. formulating conclusions
15. relating to what's learned, getting a overview
16. conditions and possibilities for application
III. REGULATORY ACTIVITIES
cognitive
17. testing progress and learning process
18. controlling progress and learning process
19. taking recovery actions
20. reflecting learning process and progress
21. evaluating
affective
22. controlling and regulating concentration
23. keeping motivation
24. generating feedback
25. relating results to strategies used
26. self-assessment

PHASES OF TECHNOLOGICAL DIFFUSION

The three phases of technological diffusion are shown in Figure 3. In the *substitution* phase, the technology replicates or automates the existing instructional practices. The technology is used for activities which people already do in education, e.g. drill and practice exercises on the computer refer to the use computers as electronic paper. This kind of use is not bringing real change in education, and by its character will therefore not meet the real needs of education in an information society as discussed above.

In the *transition* phase, new instructional methods begin to evolve, for example the use of e-mail in foreign language classes to communicate with peers who are native speakers. In this phase the technology is used for activities for which it was not necessarily brought in, and it is challenging old instructional practices.

In the *transformation* phase, the final phase of technology diffusion, the technology provides completely new instructional situations and the old customs may become obsolete. The instructional tasks for which the technology was originally acquired, may no longer be desired.

1. SUBSTITUTION
Automates existing instructional methods

↓

2. TRANSITION
Instructional methods begin to change

↓

3. TRANSFORMATION
Entirely new instructional methods

Figure 3. Phases of Technological Diffusion (Itzkan, 1994)

The underlying rationale of the phases of technological diffusion is that it is a mistake to suppose that new technologies will continue to fit existing or old practices. When we continue to use ICT only for substituting existing practices, ICT will not contribute to solutions for today's problems in education. We might be left with only artificial interventions that by nature provide us no way out for the problems of continuous harsh budget cutting (solution: more money), multicultural students (solution: more teachers), a continuous changing economy (solution: more specialized subjects), and a threatening non-labor market (solution: more study).

It is important to note that in a traditional, mostly teacher oriented educational setting the teacher is completely responsible for the arrangement of most of the learning activities. It is inevitable that the role of the teacher will change more and more if the student is more actively involved in his or her own learning process and ICT is adopted to support an increasing number of learning activities.

Although it is uncertain to what amount this shift will take place and how much time this will require, the direction of future change is clear: the learner will become more responsible for the arrangement of his own learning process. Or in other words, a new balance between student oriented and teacher oriented arrangements are needed to have our education meeting the challenges of the information society.

An important question in this context is to what extent our present education systems are already changing in this direction and whether the use of ICT is reflecting the transition phase.

WHERE ARE WE IN THE EARLY 1990's?

Where the first chapter of this paper is dealing with the question of the future direction of education and the potentials of ICT in instrumenting the future, this chapter discusses where we are in the early 1990's. Knowing where we are is important baseline information for policy makers and those in charge with shaping the future of our education, as it provides the starting point for determining the route to the future.

The IEA Computers in Education study

The Computers in Education study of IEA (International Association for the Evaluation of Educational Achievement) provides information about the status of information technology in education in a number of countries in 1989 and 1992. The major aim of the study was to build a knowledge base from which answers about the *what and* the *how* of the use of computers in education could be obtained.

It is important to realize that the Computers in Education (CompEd) study took place in a period during which personal computers were the dominant forms of information and communication technology uses in schools. When the preparation of the CompEd study started in 1986, personal computers could almost not be handled without a basic knowledge of» programming, while by the early 1990's computer users had access to many easy-to-use tools. During the 1980's, due to many initiatives of schools and teachers and stimulation policies of governments, computers also became available to schools. They were mainly used for computer literacy type of courses (in secondary education) and electronic drill-and-practice exercises (in primary education).

The CompEd study focused on primary and secondary education. Data were collected in 1989 and 1992. In 1989 20 countries participated in the study with national samples of (both computer using and non-using) schools, and using as well as non-using teachers of computer education, mathematics, mother tongue and science. In 1992 data were collected at school, teacher and student level in 12 countries.

The general broad indicators for which quantitative data were collected in each stage are listed in Table 2. The rationale for selecting these indicators has been extensively described in CompEd publications, for example Pelgrum & Plomp (1993).

Table 2

Overview of main indicators collected in 1989 and 1992 in the CompEd study

Educational level	**Indicators**
Country	*National policies* School system
School	School policies Experience with Hardware availability Software availability Attitudes school principal Organization of computer Type of use Staff development Number of using
Glass/teacher	Teacher use Teacher knowledge Teacher training
Class/student Student attitudes Student school use Student home use	Students knowledge

Altogether data about the use of computers in education have been collected from over 20,000 teachers, 10,000 schools and 150,000 students.

Some exemplary results

The results of the CompEd study have been described in numerous publications (for example. Pelgrum & Plomp, 1991, 1993; Pelgrum, Plomp & Janssen Reinen, 1993). Here we present only a few results based on the data of four industrial countries (Austria, Japan, the Netherlands, USA) to illustrate the use of ICT in education was still in its infancy in the early 1990's, even in industrial countries.

From the results the picture emerges, that during the 1980's and the beginning of the 1990's the number of computers available in schools had rapidly increased. A further growth can be expected. Noteworthy is the 'late start' of Japan.

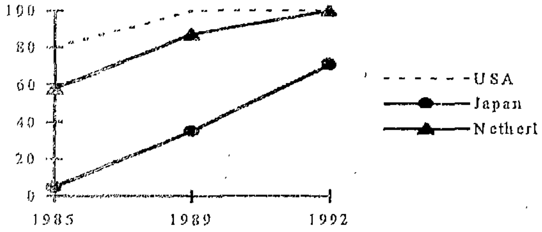

Figure 4. Percentage of lower secondary schools with computers

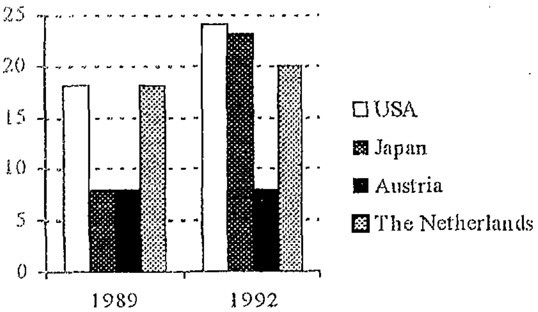

Figure 5. Average number of computers in lower secondary schools

In 1992, however, the number of computers in typical schools was just enough to allow one class at a time to use computers. This means that even in industrialized countries in that year the hardware infrastructure in general is not sufficient to allow a broad and intensive use of information technology within the schools.

Particularly important in the recent past has been the development of electronic networks. The CompEd data show that in 1992 there are hardly any schools which have regular access to external networks, except for the USA where 17 % of lower secondary schools and 12 % of elementary schools were using computers almost weekly for access to external networks (Pelgrum, Plomp, Janssen Reinen, 1993, p. 17).

The lack of sufficient software was a major problem in 1989. This substantially decreased between 1989 and 1992. The most used didactical approach was drill & practice and tutorial programs, which means automating already existing methods (that is, substitution use of technology).

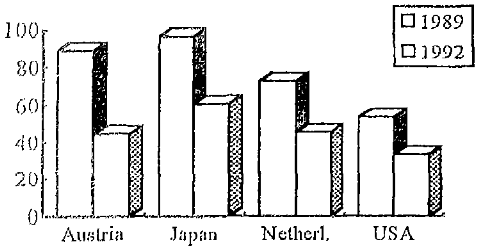

Figure 6. Percentage of lower secondary schools lacking software

The most popular use of computers at schools in 1992 was to learn students how to use this new technology.

Many students were attending computer education classes. The use of computers as tools in existing subjects was still marginal, as the figure shows. The percent of students using computersJn other subjects was even less than the percentages in mathematics.

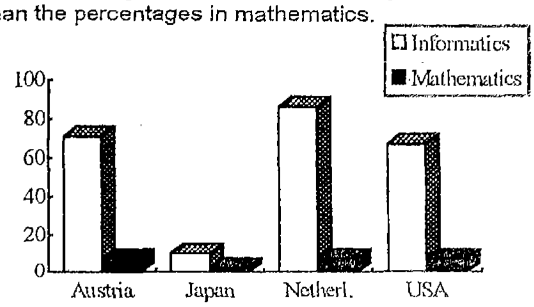

Figure 7. Percentage students in lower secondary schools working with computers in informatics and mathematics classes

Integration of computers in lessons was still seen as requiring considerable additional time-investments. This referring to a major concern. Future use of ICT in education means integration in daily practice of learning and teaching. For such a change in education practice teachers' time need to be made available.

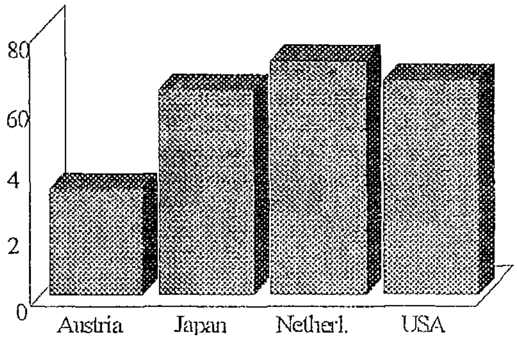

Figure 8. Percentage lower secondary schools reporting insufficient time to integrate computers in lessons

The expectations regarding the added value of computers were quite high, as shown by the opinions of schools principals.

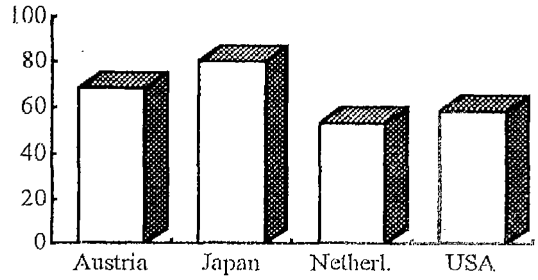

Figure 9. Percentage lower secondary school principals who say that students are more attentive when computers are used

Many analyses were conducted on the data. For instance, Tuijnman & Brummelhuis (1993), Brummelhuis (1995), Janssen Reinen (1996) showed the complex interactions of a number of factors

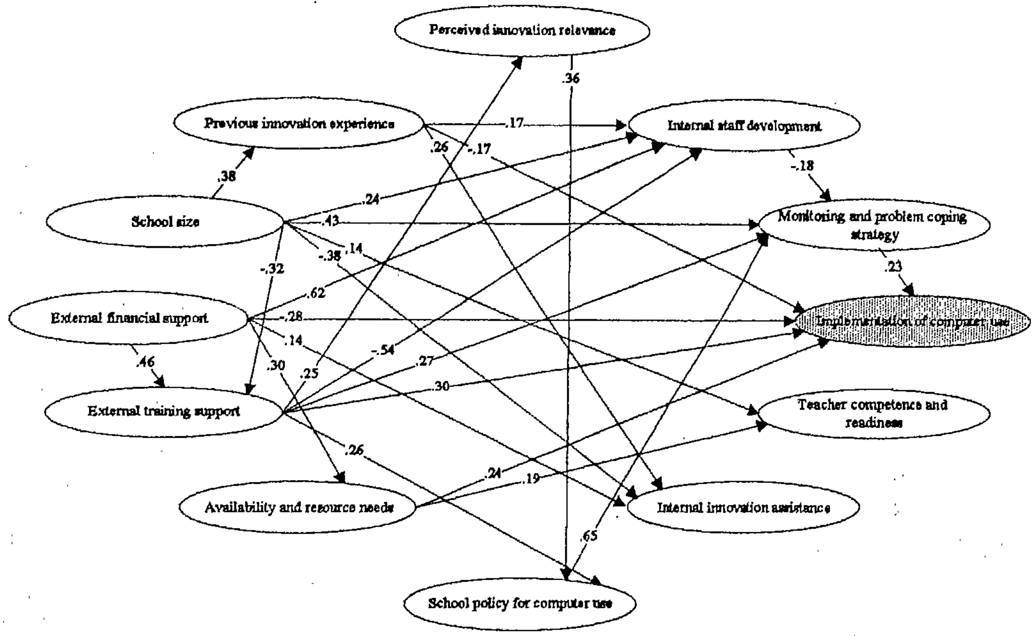

Figure 10. Factors influencing the implementation of computer use in education
(Source: *A.C.A. ten Brummelhuis, 1995)*

influencing the degree of infusion of computers in the school curriculum (see, e.g., fig.10) It is important that policy makers understand that there is not a single factor that determined the integration of technology in education, but a group of interrelated factors, which may differ in different stages of introducing information technology in education. Besides, certain necessary conditions have to be fulfilled, such having a computer co-ordinator in each school.

EN ROUTE TO THE FUTURE

Our analysis so far leads to two conclusions. At first, our society does need increasingly learning situations responding to the need for *flexibility* (adaptability to different needs), *accessibility* (learning when and whenever suits best) and *support* (an adequate learning infrastructure to assist learners). To make this happen, more emphasis should be given to student oriented arrangements, and ICT provides powerful possibilities to realize this. Teachers, being key actors in learning and teaching processes, need to be trained in designing and organizing such innovative teaching and learning environments. Besides, the learning infrastructure of the schools need to change accordingly, both the content of what is being taught as the materials and technical infrastructure (see Figure 2).

A second conclusion, drawn from the CompEd study, is that in the early 1990's ICT use in education is predominantly the use of computers, reflecting a computer use that can be characterized as substituting already existing didactical functions. Besides, the integration of technology in the daily practice of the school is a process influenced by many different factors.

So the question is how to get "en route"! This question will be discussed by applying a system analysis point of view.

A system approach

From the perspective of a system analysis approach, we could regard society as the relevant environment of education. Education is defined here as the set of all educational practices; society as the place where education finds its people and resources, and to which it delivers its results. Schools and teacher training institutes are, among other institutions, subsystems of the education system.

Systems tend to pursue an equilibrium with its environment. They tend to organize their internal processes and exchange with the environment in such a way that they stay stable and viable. For that, they have to cope with the complexity in their surroundings and they do so by controlling variety. The variety of educational needs in society, for example, is balanced to the variety the schools can accommodate. No school can meet all of the individual learning characteristics of its students. In most cases, this is not much of a problem and most people accept the fact that a school offers a limited variety of learning possibilities. However, in order to stay in balance with the (learning) needs of society, schools have to maintain their level of variety above a certain threshold level. When the learning offerings of a school drop below that level, too many student-learning needs cease to be met and the system gets out of balance. This imbalance could subsequently result in a decreasing number of registrants, a rise of drop-outs, less public and/or political support, increase of classroom troubles, etc.

There is a number of subsystems that surround schools such as teacher training institutes, institutions for curriculum development, test development, school support institutes, educational publishers, furniture providers, educational software developers, and others. Each of them does have a specific function for education. Together they act as the safe-keepers of education. Whenever education has a need, expressed by the educators themselves,

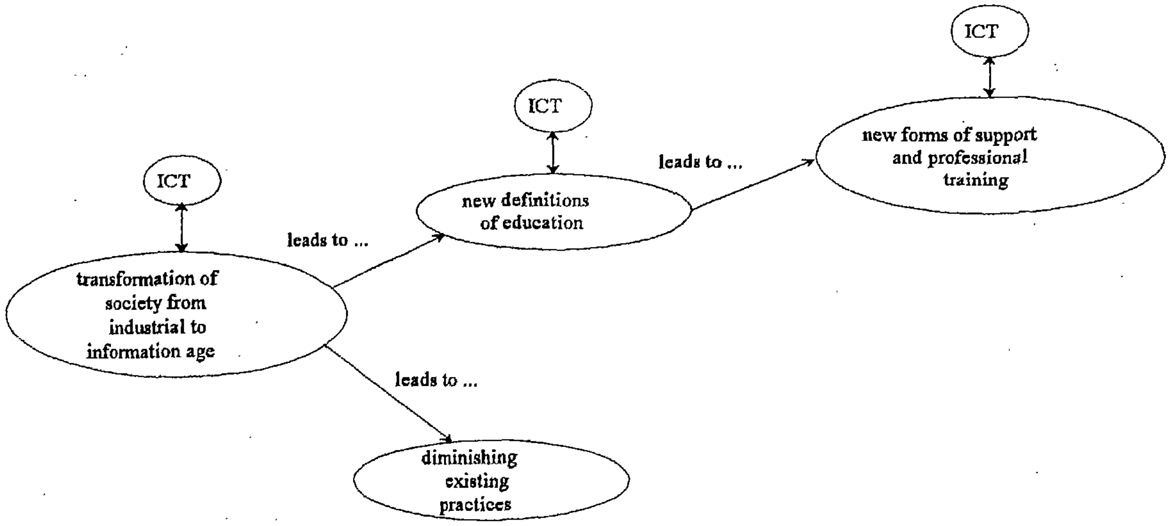

Figure 11. Transformation of society leads to new forms of support and professional training

by the management or by government administration, one of the safe-keepers will react with some sort of service by implementing small but important changes. In doing so, their (support) activities are not only defined by the existing educational system, but in turn, keep the educational system within the margins of *controllable variability*. They are designed to act in this way. But this makes them more the custodians of the present situation, than the change-agents of education. This situation refers to a fundamental problem if one wants to bring about real change in education.

Besides these continuous adaptations, there is another kind of change emerging in education, namely change that goes beyond the boundaries of controlled variety. As long as education succeeds in answering the needs of society, it fulfills its function towards society and it stays stable and viable. But when the demands that society puts to education can no longer be met by more variety, the system itself (i.e. education) needs to change.

It is our belief that this is the case nowadays, where we concluded that our society has moved towards a new paradigm, characterized by 'information society'. This is demanding a new relationship between education and society, or in other words implying a need for transformation of education as well as new definitions of education. These new definitions of education will come from the learning needs and the possibilities in the information society. They should not be regarded as a linearly developing out of today's education. The consequences for education of the transformation from the industrial society into the information society is depicted in figure 11.

In order to facilitate this transformation, it is required that the education system revises its relations with society, takes its needs seriously, and gives its demands the highest priority. These demands, were already mentioned in the first chapter as the challenges the education system is facing.

Developing a future for learning

In order to prepare schools and teachers for education of the future, the current schools and teacher training institutes should shift their focus from serving the current education to serving what emerges as the education of the future. They have to create both room and opportunities in their program for such a transformation. This causes a dilemma, as schools and teacher training institutes cannot refrain completely from providing current education with teachers that can function in the existing situation.

A solution for this dilemma is to create a transition period from the present situation towards a future situation in which education will get its new shape. This implies stimulating and strengthening the development of something 'new', while 'old' is still existing. During such transition process 'old' needs care and attention, but should not prevent 'new' from growing. 'Old', that is our present schools and teacher training institutes, should be challenged to emerge into 'new'. But at the same time, 'new' needs stimulation and incentives, and should not be hampered by 'old' trying to continue its old equilibrium with its environment.

This is asking for a program of action that has to provide bridges from "old" to "new". The program has to be designed in such a way that it creates opportunities for new definitions of education and at the same time challenges educators from existing practices to participate. However, the main focus of the program should be on generating and supporting 'emergent practices' of learner oriented arrangements with ICT as a medium, as well as preparing both teachers and student teachers for the 'emergent practices' in primary and secondary education. This refers to the use of ICT as medium in the schools, but at the same time an aspect of the teacher profession and therefore of teacher (inservice) training. A coherent research and development program, in combination with an adequate monitoring process of first hand experiences is expected to create a clear picture of both tomorrow's teacher training and the educational practices in the field for which teachers are being prepared. The Committee on Multimedia in Teacher Training (COMMITT) will propose such a program in its final report, that will be published in educational practices in November 1996.

Commission I

NEW INFORMATION AND COMMUNICATION TECHNOLOGIES IN FRENCH EDUCATIONAL SYSTEM

Jilles Braun

DIRECTION DE L'INFORMATION ET DES TECHNOLOGIES NOUVELLES
BUREAN DES TECHNOLOGIES NOUWELLES POUR L'ENSEIGNEMENT
(FRANCE)

WHAT FOR WE NEED NEW TECHNOLOGY IN THE SCHOOL?

Since seventies France has started to introduce informatics in utterly deferent forms into educational system. Hence, after 20 years and after realization of National programs ("10000 personal computers", "100000 personal computers ", "Informatics for everybody"), all lycees and colleges were equipped by computers of different kinds and configurations and a lot of teachers have passed three - month or more long courses of pedagogical informatics, short term approbation in the permanent educational system became everywhere, though the rules mentained traditional.

Software has introduced into educational media. It's interesting to mention, that the goals, put in the beginning of seventies, concerning application into teaching field, did not change sufficiently, contrary to technical possibilities, which develops very quickly. These goals might be formulated in the following way:

- Modernization of education and school life management with the help of the development and application of multimedia, software for students, school regulations etc.
- Teaching of the base for utilization of new technologies in the information and communication fields; even just now and surely in future we shall touch with necessity of appropriate use of diverse information and communication technique in our everyday life. In order to reach this, the educational system ought to provide all the students by a set of skills, which might allow them to use this technique rationally. This goal is put either on the level of theoretical knowledge or on the level of practical skills and life principles.
- Mastering of the technology, put into new professional tools and their use; really, how one can prepare the students to the tomorrow specialities without concerning mentioned necessity? This factor plays a special significance for mastering of specialists for industry and service field.

- Taking into account of the necessity of developing school subjects in connection with the appearance of new media for information processing and communications. One ought to take into account this concerns all the school subject beginning from musical education, history, geographic up to mathematics.
- Introducing of information media into education.
- Really, informatics is extremely effective educational additional tool. It will allow teachers to meet the challenge, which time throws to school, with confidence.

WHAT MEDIA DO THE SCHOOLS POSSESS?

Currently in France in all kinds (12 000) of secondary, technical and professional education there are approximately 400 000 personal computers. These amount consist mainly of compatible PC.

One ought keep in mind that all these PC might be supplied by necessary set of peripheral equipment: printing devices, scanners, sound plated, reading devices CD ROM, physical interfaces, modems etc.

There are about 15 000 reading CD ROM devices in the lycées and colleges.

It seems that a new informational space is standing out already, which successively will take it peace in few years. It's formed on the base of two evident tendencies:

- significantly increasing spreading of multimedia, allowing CD ROM use;
- communication development, due to introduction of inter school informational networks and linking up to state communication nets. A lot of educational institutions started to develop their own internal networks on the base of their own informational media. In the nearest future these process will extend. Along with it currently the experiments are carried out to link these networks through Internet (400 institutions take part in this process today).

However every kind of practice is based on the existing of software in the educational institutions, which are used in the everyday pedagogical activities.

These are divided into:

- so called "professional" software, which are designed specially for use in the enterprises: operational systems and program languages, general means of institution automation, specialized software;
- so called "pedagogical" software, which are designed and used especially for pedagogical aims. We mean here professional software, intended for teachers (or students).

They are designed by publishers, information service films in the private sector and National center of pedagogical documentation, state institution of Educational ministry.

As for acquisition of software by institutions, the government provides 80 millions Franks (16 millions US dollars) in its annual budget for the secondary school educational system. Ministry has developed special order of acquisition of rights for software use (joint license), that allows to decrease the cost of software, which significance for pedagogical process is confirmed by expert commissions, while the opportunities for spread are large enough. Thus, about 100 000 software products are purchased directly by school institutions.

EDUCATION AND COMMUNICATION SUPERHIGHWAYS

National educational system attempts not *to* lay behind the main directions of informatics development. The activities, concentrated in large united projects on the national level and on the level of educational districts, are concerned mainly the following:

- opening of the institutions for entire world as continuation of means for the aim of assistance to combine their information resources into united network for use of communicational means and providing access to remote sources;
- joint use of information resources by several educational institutions or even on the level of educational district: joint developed data banks, technical and pedagogical assistance for users and institutions;
- joint activities and discussions (in the framework of different forums, institutions, groups of the teachers or students on the international arena or international level;
- distance education and distance teaching: permanent training of the teachers, distance learning of the optional subjects in lycées.

Simultaneously governmental institutions and the Ministry of Education itself develops services, compatible with Internet standards. A special service was opened with the address: *http:\\education.gouv.fr* in network *Edutel* of Ministry of Education. It present an easy and effective access to the block of internation services, concerning all types of the problems in the French educational system. Different types of services were opened also in a lot of educational districts.

The interconnections, established with international educational systems, have also accepted new development. It's possible in particular to mention initiatives, undertaken in co-operation with educational service *Campus World* of British Telecom and Canadian school networks. The most of educational districts and school institutions have also introduced to European co-operation on the base of earlier extended relationships.

THE ORGANIZATIONAL STRUCTURE IN THE FIELD OF NEW TECHNOLOGIES IN THE MINISTRY OF EDUCATION

In order to be able to answer on the questions put by new technologies in the information field, Ministry of Education has created new structure on all levels: national, educational district, educational establishment.

At national level the Department of scientific information, new technologies and libraries has been authorized to define and evaluate the Ministry policy in the educational use of new technology in the information and communication field. In this field the Department acts mainly in the following three directions:

- *watching on the technological situation:* actually, in this rapidly developing field it's necessary to analyze possible short-rate changes, in order to make necessary decisions just in time;
- *pedagogical investigations and experiments;* in every school or university subject it's necessary to confront the potential capabilities of these technologies with everyday reality in teaching;
- *generalization and spreading:* in case the experiments are evaluated positively, it's necessary to start to spread the innovation: information, training novice and continuing oraining of the teachers), purchasing and management of necessary means and software, structure creating for their support and development etc. Finally new technologies in the school become the subject of new administrative rules, whether the idea concerns a new learning subject or it concerns the tool, which all the teachers need: many school curriculum take into account the factor of "informatic technologies".

At the level of every educational district special appointment of the Inspector on "new technologies" was introduced for to watch for establishment of national policy in this region. In the frame of their competition they must take part in defining of teachers training contents, present recommendations to institutions, concerning technical equipment, determine the list of purchasing necessary equipment and adjustment in co-operation with territory communities (municipality), general councils and regional councils to organize the senvice of the technique, experiment control, carried out in their educational district, to inform about national policy and to watch for its use in co-operation with inspectors, to spread the educational materials and documentation.

In each educational establishment the administration and teachers ought to formulate the pedagogical concept of their institution, to define the structures, necessary for its realization and, naturally, to deal with the main subject - to teach the students most effectively.

THE MAIN TASK IS TEACHER'S TRAINING

In conclusion let's underline the specific importance of primary and permanent education and training of the teachers in the process of new technology introducing. Taking into account the role, which new technologies play in school curriculums, teacher's training, preparing of specially adjusted means and software are three directions, necessary for success results of the policy in field results of educational informatics.

No doubt that the primary training and permanent training are the most delicate moments in the problem to be solved. In every educational district in France special structures are engaged in the teacher's training and in the use of informatics in the learning process: IUFM (Institutes universitaires de formation des maitres) for the primary training, MAFPEN - for permanent training. It's necessary to provide the teachers and students/probationers by data, that might allow them in future changes, caused by extending of information and communication technologies extended.

Thus, French educational system wants to use the results of extreme technical revolution of the 20th century. Now, when the informatization of the society already does not depend on us, because it's inevitable, the idea is to transform the technological necessity into educational project.

DISTANCE EDUCATION: CURRENT SITUATION AND PROBLEMS

Jan Wibe

CENTRE FOR CONTINUING EDUCATION ALLFORSK
NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

INTRODUCTION

The author of this paper is working at the Centre for Continuing Education at the Norwegian University of Science and Technology. Our main task is to deliver continuing education for teachers on university level. Most of our courses are traditional on campus courses but we are gradually shifting to Distance Education to reduce costs and improve availability. The services we have used so far in Distance Education are radio, video, videophone and datacommunication. Our main source of income are governmental and university funding. The students normally don't have to pay for the courses.

Let me quote Tony Bates (Tony Bates: Technology, Open Learning and Distance Education, 1995, ROUTLEDGE, London and New York) as an introduction to this paper:

Technology developments will mean the end of distance education as a discreet educational activity

and

Recent technological advances are making the distinction between conventional and distance education more and more meaningless. Technology will dramatically impact on all educational institutions, and change their nature.

My paper will be based on this statement which I find very much in accordance with technological and educational developments in the last years.

My presentation will cover the following main items:

- *A short history of IT in education*
- *IT in education today: The Norwegian plan for 1996-99*
- *Technology*
- *Distance education*
- *Some experiences in technology-based Distance Education*
- *Visions and problems*

HISTORY: IT IN EDUCATION

The use of IT in education is roughly 25 years long. In this section, I will try to identify some trends.

Nearly from the beginning, we can identify three different trends of development:

a. Computer science as a subject.

b. Computer assisted learning.

The use of the computer in learning school subjects.

c. The use of standard software packages like word processors, spreadsheets, databases etc.

This development is well documented by Proceedings from IFIPworld conferences on the general theme:

WCCE: World conference on computers in education.

Up to now, the following conferences has been arranged:

•1972: Amsterdam
•1976: Marseille
•1981: Lausanne
•1985: Norfolk
•1990: Sydney
•1995: Birmingham.

These conferences has covered education from the kindergarten level up to the university level and in my opinion gives the best documented coverage of what has happened during these 25 years.

One significant trend has been what I will call the «religious movements». Some issues:

• The discussion between computer scientist and teachers about programming languages: Basic or Pascal.
• The use of LOGO.
• The electronic teacher - the idea of substituting the teacher by a computer.
• The text, spreadsheet and database syndrome.

These issues raised very strong opinions and feelings bordering on religious feelings.

What is the religious movement of today? Certainly Internet and WWW is such a one. But it is quite different from the former ones because of the widespread use in all educational levels. The former movements were restricted to fairly small members and educators generally were sceptical. For perhaps the first time in the short history of IT in education, we can see a real mass-spreading and a fantastic variety in the use of the technology.

Some characteristic examples:

Educational institutions and individuals presenting themselves with Web-pages;

International school-projects;

On-line courses on Web

etc.

Has IT been a success in education up to now? In an IFIP working conference in Santa Barbara in 1991, this issue was raised and the answer was negative in relation to general education. On the same time, it was a success in vocational education and the reason may be that it is much easier to introduce computers in vocational education. It is simply to base the education and training upon what is done in industry. Whereas in general education you have to invent to a certain degree what you shall use the computer for. Again I must say that very much has happened in the later years since 1991. We feel that educators generally have changed opinion from sceptical to positive. Perhaps this shift has come by the general use of IT in society. Everybody can see how dependent we are of computers in daily life and the consequences for education in general is that we must prepare the students for the society.

An interesting aspect has been the shift from the small software packages with a narrow use to more general and open packages. Let me give mathematics as an example. In my institution we have given courses for teachers on the use of IT in mathematics teaching. After some discussion we have ended up with five standard packages:

• graph plotters
• spreadsheets
• symbolic manipulation (Derive)
• geometric packages (Cabri)
• word processors with mathematical editor.

These packages covers most of what we need in mathematics in upper secondary education. I must say that in lower levels, we often need more subject oriented packages. This is especially true in special education for handicapped students.

All along the way in these 25 years, three main obstacles for a wide-spread use in education has been:

• Lack of equipment
• Teacher education
• Curriculum adjusted to the use of computer.

As to these three factors, I am fairly optimistic for the future:

• The equipment gets cheaper and cheaper.
• We can see a strong development in most countries in upgrading the curriculum.

Perhaps the most difficult case is the teacher education side. Without upgrading the teachers knowledge of how to use computers, very little is achieved in the classroom. Lack of funding for teacher courses is the serious problem. In industry, it is common knowledge that to develop and make new products based on IT, the workforce must be well educated. The same way of reasoning is done for education but in most cases it is not followed up by relevant funding. The situation may differ from country to country, but I would say that too little has been done in teacher education up to now.

IT IN EDUCATION TODAY: THE NORWEGIAN PLAN FOR 1996–1999

As an example of the use of IT in education today, I will shortly describe the plan from the Norwegian Ministry of Education, Research and Church Affairs for the period 1995 to 1999. It may be somewhat special because it covers all levels in education:

• Primary and lower secondary school
• Upper secondary education
• Higher education
• Adult education and continuing education.

The benefit of this is for example that the Higher education level is seen upon as a resource for research and development for the lower levels in teacher education and didactic work with the use of IT in different school subjects. An important aspect of this may be that distance education is looked upon as an important means of educating the teachers.

The plan has 28 different Actions in separate areas. In the following, I will give examples of this work areas with relevance to this presentation:

Development of teaching methods:

Action 2 - Didactic use of IT - research and development

Action 4 - IT-based teaching methods in adult and distance education

Action 8 - Girls use of IT

Action 9 - Students as a resource.

Information wells:

Action 12 - International co-operation

Action 13 - The Norwegian bookcase - creating information wells.

Teacher education:

Action 22 - Continuing education (lifelong learning)

Action 23 - The teachers of the teachers.

Technological infrastructure:

Action 24 - Connecting schools to Internet

Action 28 - National licenses for software.

In this year, the government are funding projects for about 5 million US Dollars in these areas.

To illustrate the actions, I will give some examples of projects in the distance education area:

Action 24 - Connecting schools to Internet

Through Norwegian Telecom, the schools are offered ISDN-connection to Internet. In this way we will have made a national infrastructure which enable the schools both to receive and give distance education courses. Especially important is this in educating the teachers in the use of IT in education.

Action 13 - The Norwegian bookcase - creating information wells.

Norwegian Telecom has invested much money in creating so-called information wells. They contain for example detailed information about school subjects and the use of IT with links to information resources in the whole Internet.

In my department at the Norwegian University of Science and Technology, we have a project for the government which involves many of this actions.

The core of the project is to develop didactic models for the use of IT in mathematics, physics and languages.

A didactic model for use of software packages must contain:

a) at least one example on the use of a specific software package in education related to the curriculum;

b) how to plan and carry out the instruction in the classroom (didactic discussion).

Example: The use of software packages for graph-plotting.

Structure of model which will be presented on WWW:

1. An exercise
2. Solution of the exercise:

• a graphical picture (preferably as a process - not static)

• short text related to the solution.

3. Didactic discussion of a more general nature related to the example.

This text will not be shown on the screen but will be available for downloading by FTP

When the project is finished by the end of this year, we will have a basis for educating teachers by distance education. Most of the course material will be on the Web-page and in addition we must develop supplementary material and exercises.

In addition to this governmental initiative, I will also mention two important aspects for why Distance Education is developing very fast in Norway.

• The role of Norwegian Telecom:

Funding a wide variety of Distance Education projects.

• Norwegian Executive Board for Distance Education at University and College Level:

Funding projects with Distance Education on higher education level. The target group of the courses are very often teachers on lower levels.

TECHNOLOGY

In this section, I will shortly describe the technology used in Distance Education. A lot of book and papers have been written on this subject and I see no need to duplicate these.

In all kinds of education we are basically using three kind of senses:

1. to see
2. to hear and speak
3. to read and write.

In ordinary classrooms, we use all these senses in a natural way.

Distance Education originally was based upon correspondence courses where the student read texts and wrote exercises.

Next step in the development was radio and much later TV. But it was still not interaction between teacher and students like in a classroom.

Real communication came with the telephone. TV combined with telephone, is now often used.

Computerbased communication with email came around 1985. Basically this is also of the «read-write» type, but it reduced drastically the reply-time in comparison to ordinary mail. Of course it also had some other benefits.

The great leap forward, came with the introduction of new technology-based communication like videoconferences and PC to PC communication.

And the last step is on-line courses on WWW. Try a search with key-word «on-line courses» using Alta Vista and you will see how much is offered already.

What we are now waiting for is the communication superhighway on broad-band which will enable us to communicate nearly as good as in the classroom. The words are already invented for this with expressions like:

• The virtual school,
• Global education,
• Classrooms without walls,
•The electronic university etc.

In the following table, I will try to sum up what I have written in this section so far. Beware that I am using one-way and two-way communication in a little unusual way. You may say that email is a two-way communication but I am looking into the interaction between sender and receiver. By one-way I mean that there is not simultaneous communication between the two parts. By two-way communication there is a simultaneous communication like for example by using phone.

Table

Media of communication
in relation to telecommunication technologies

Basic senses:	One-way:	Two-way:
Read and write	E-mail E-conferences News-groups	PC to PC communication
Hear and speak		Phone
See	Television	Videoconferences
Multimedia:	**One-way:**	**Two-way:**
Internet	E-mail E-conferences News-groups WWW FTP Telnet	Phone Videoconferences

Let me sum up this section, by saying that the technology is already here (or nearly so). What we still not have, as so often before in the history of IT in education, is the didactic use of the technology in Distance Education and in the classroom. This is the real great challenge for the time ahead.

DISTANCE EDUCATION

Three characteristic elements of Distance Education is that it allows the student to study in a flexible manner with respect to:

• Distance
• Place
• Time.

The old correspondence schools fits very well into this thinking, but the emergence of new communication technologies often narrows the students freedom in choosing place and time. We may say that the Distance Education situation more and more is like traditional education in classrooms.

A short discussion of these three factors in relation to technology. The discussion will not be complete but rather illustrated with examples.

Distance

By tradition, we imagine a very long distance between teacher and student in Distance Education. After all this was the very reason why we used Distance Education. If the distance was not there, the student would sign up for regular courses.

One example to illustrate the new situation.

Traditional lectures at universities are given in lecture-halls. We have lately seen examples of lectures with cable connections to other lecture halls at campus or at students dormitories. Or for that matter to any place on the earth.

New two-ways communication technologies enables us to follow lectures from distance or near. But opportunity to follow a course from long distance is the main factor and will be so.

Place

Another important factor in Distance Education is the opportunity for the student to study at any place. The correspondence courses gave total freedom for choosing place for study. The introduction of two-ways communication technologies have limited this freedom. You must be in a place where the necessary equipment is available. For the moment we have not built up a national infrastructure with such places. In the not so far future with super highways for communication on broad-band, I expect that every home will have the opportunity to communicate freely and cheaply. As for the old correspondence schools, we will again have total freedom of place to study.

Time

The least important factor in Distance Education is that the student can study at his or hers own time of choosing. Normally after work and when no tutors were available. If you want to have on-line communication with tutors and other students, you will not have this freedom any more. And this should be the final proof of the quote from Tony Bates:

Technology developments will mean the end of distance education as a discreet educational activity.

In the end of this section, I will present a table which give some examples of user areas in relation to «Rooms at the virtual School». All areas are based upon on-line courses I have found on the Web with concrete examples from real courses. My intention with this table is not to give a complete list of «Rooms» but rather to show .the variety of activities in the virtual school.

Rooms at the Virtual School	User area
Information about and registration for courses	Marketing of courses Registration Course inf. Course Description Other inf. from school
Administration and information for students at courses	Information about the on-line classroom and technical assistance Grading Guidelines Course Information Course Syllabus Course Credits Tutorial Support Assignments Order Products Newsflashes Archief, E-mail addresses The Kiosk

VISIONS AND PROBLEMS

In the first section of this paper, I wrote that «The use of IT in education is roughly 25 years long». Thinking about what has been achieved in these 25 years on the technological side, we can only guess what will happen in the next 25 years. It is not difficult to imagine a virtual school with nearly as much opportunity for communication as in the real classroom. And the costs for communication will be so low that we can afford to study at home rather than go to a school for regular classes.

So far the bright new technological world, but as all of you know, we have problems here and now.

One problem which is often mentioned is the difference between countries which can afford to build up the necessary technological infrastructure and nations who can not. We can already see this today by looking on the blank spots for Internet with great parts of Africa as an example.

Another problem is that systems doesn't function as they should. Communication breaks down, printers doesn't function etc. A regular staff meeting here in Trondheim very often contain sections with complaints about malfunctioning of systems. I suppose it is the same in other places. This is a temporary problem but it creates much discontent here and now.

A serious problem when we look upon the use of IT in education and not only Distance Education, is that the teacher educators are so badly prepared both technologically and didactically for using new tools. We are educating a generation of teachers with too little understanding of using the new technology in the different subjects. This will make in-service training of teachers much more important. This fit's very well into that 1996 is the year of «life-long learning».

Another problem and also for the future is that tutoring is costly. We may have excellent conditions for all kinds of contact between students and teachers in Distance Education, but we can't afford it. This is a general problem in education. Look upon a classroom with 30 students and one teacher. How much personal tutoring gets each student?

We think and act in old paradigms when new ones are emerging. Teaching and learning in a virtual school is different from class-room-based education. Educators need to learn the necessary technologies first of all and also how to use them in education. From my experience in Norway and other countries, this is a critical factor.

When we can identify problems, we can also do something with them!

If I had been asked 15 years ago about the available technology for IT in education and Distance Education in 1996, I would not have guessed the situation today. I suppose it is the same situation 15 years ahead to 2011. We may have some visions for the future, and I think they are more soundly based than in 1981, but the technological development usually surpasses our imagination. Educational use of technology is another matter with different scenarios for the future. The worst scenario with only virtual schools, will not happen in my opinion. Man is essentially social and want to get together. Even the best videoconferencing systems can never substitute face to face contact. After all the human factor is the essential one, not technology in itself.

Discussion

UNIVERSITY TELETEACHING CENTRES: A CENTRAL AND EASTERN EUROPE PERSPECTIVE

Roumen Nikolov

DEPARTMENT OF INFORMATION TECHNOLOGIES
FACULTY OF MATHEMATICS AND INFORMATICS
OF SOFIA UNIVERSITY (BULGARIA)

1. GENERAL ISSUES AND TRAINING NEEDS

Like all other Central and Eastern European (CEE) countries Bulgaria is experiencing a dramatic change in all areas of its society and it is seeking to create democratic institutions and market economy. As the political and economic reforms are not at a satisfactory state, the Bulgarian economy is still in a deep crisis. There is a lack of modern economic and management practice in the Bulgarian companies and the lack of enough public support and understanding of the political and economic changes. In the long run, economics and management understanding is critical to a successful transition and economic growth. In addition, the urgent need to turn around the existing companies and at the same time to create favourable conditions for emerging private enterprises require better knowledge in economics, business, and company management. This makes economics, business and management education at university level of utmost importance to the development of the country. This fact is politically recognised by the Bulgarian government, which would support any valuable initiative. However a mass education could hardly be achieved without applying the methods of the new educational technologies based on Communication and Information Technologies(CIT). As the Bulgarian society and economy is getting more open, a mass foreign language education is also needed, along with training in application of CIT.

The education used to be the main instrument for ideological influence before 1989 and the advanced educational technology methods had not been widely applied. Only few teacher and lecturers are well prepared in this field now both at a secondary school and university level. Most of the teachers and lecturers have to be trained in applying modern curriculum and instructional design methods, instructional technology, educational instrumentation, etc.

Some new ways for opening the Bulgarian education towards the European standards are needed. The traditional forms of achieving it - by student and staff mobility, has its disadvantages, especially for the long term visits. The main problems are economical, political, geographical, social, etc. When a student goes for a study abroad the knowledge he/she acquires can not be easily disseminated in Bulgaria because the students usually leave and study in an isolated environment and in some cases - the students do not come back to the country. The teleteaching option, combined (when possible) with a short term student/staff mobility scheme, gives quite more opportunities and solves some of the problems which appeared. From the other side the teleteaching provides opportunities for developing a school and university presence on the Internet and thus making this institutions transparent for the outside world. In such a way the exchange of ideas, materials, multimedia educational software, curricula, and people would be extended, and the Bulgarian education would be drawn closer to the European standards.

There exists a belief that the traditional departmental structure of universities is reaching great obstacles in fulfilling its usefulness and that new organisational structures are needed if universities are to provide education for the masses with the diminishing resources which are available to them. At the same time, universities are facing increasing pressures from the outside. Tuition fees are rising far beyond the ability of middle class family in the CEE countries to pay, and government grants for research and education are drying up as governments face budgetary pressures. The telematics based Distance Education (DE) is considered as an answer of the new challenges in the field of education. It opens new dimensions for the educational systems of Bulgaria and the other CEE countries.

2. BACKGROUND

2.1. An EU Copernicus Project on Distance Education through Telematics Networks

In January 1995, the EU Copernicus Project COP1445: «Flexible and Distance Learning through Telematics Networks: A Case of Teaching English and Communication and Information Technologies» began. The partners were: Sofia University, Faculty of Mathematics and Informatics and Faculty of Economics and Business Administration, Sofia, BG; University of Twente, Faculty of Educational Sciences and Technologies, Enschede, NL; University of Exeter, Exeter, UK; The Technological University of Kaunas, Kaunas, Lithuania; and Glushkov Institute of Cybernetics, Kiev, Ukraina. The project aimed at:

- establishing Internet communication between the project participants:
- developing Project Data Base suitable for establishing a Telematic Research Network;
- developing pedagogical framework for teleteaching in individual and group mode and a conceptual model for flexible and distance learning system using Telematics networks.
- developing and delivering two sets of distance education courses: English (English for CIT and Business English) and CIT (CIT for Teacher Training and Business CIT);
- developing software tools supporting course development and delivery.

The Copernicus Project outcomes offer a good basis for developing the Sofia University Teleteaching Centre.

2.2. An EU Phare Project on Distance Education

The first steps in building a distance education network in the CEE (Phare) countries were undertaken in June, 1995, when the Technical Assistance Programme (TAP) for the implementation of the Trans-Regional Component of the Phare Pilot Project for Multi-Country Cooperation in Distance Education started. The TAP includes 70 experts from the European Association of Distance teaching Universities (EADTU) and the European Distance Education Network (EDEN) who will deliver technical assistance to the distance education network now developing in the CEE countries. The pilot project is based on the following main activities [2]:

- creation of a background and expertise for future adaptation of distance education learning materials in the Phare countries;
- creation of a common understanding in the Phare countries on the main European open and distance learning concepts;
- creation of a nucleus of DE trainers/experts serving as a basis in the future for the development of DE in the Phare countries;
- development of regional co-operation in human resource and DE issues in CEE countries;
- testing the feasibility of joint course development and implementation actions in the region leading to core course modules which can be adapted to national requirements and contexts;
- development of the necessary conditions for the co-operation with the distance teaching institutions of the EU;
- creating a common basis for the formulation of adequate policies and priorities in the Phare countries, at national and regional level, towards the development of relevant and efficient distance education methods and structures;
- raising awareness and creating cohesion about the national measures and actions in the field of quality assurance, customer care, accreditation and credit transfer, concerning distance education programmes and institutions;
- introduction of European standards in the CEE distance education.

A network of National Contact Points for DE has been established and in addition forty Regional DE Centres are envisaged to be developed during the second phase of the project. The paper analyses the opportunities of developing a network of teleteaching centres in the CEE countries on the basis of the Phare DE infrastructure and the on-going teleteaching projects.

3. OBJECTIVES

The main objectives of the Network of Teleteaching Centres (NTC) are:

- to provide information on the Internet for the on-line distance education courses offered by the NTC;
- to provide information about on-line courses offered by other universities and accessible via Internet, along with facilities for tree browsing, and keyword searches;
- to setup and support mailing lists and list servers;
- to setup and support: a central web server where instructors may put course materials and texts. The web servers will be configured as to allow people to send messages via e-mail as well as allowing establishment of web-based discussion groups;
- to provide access to the personnel database and statistics database;
- to support of distance collaborative training workshops and projects;
- to maintain databases containing students records;
- to provide software tools helping students and teachers locate information on the Internet:
- maintain a list of hypertext links to sources of distance education and mailing lists for discussion of teaching issues.

4. MAIN TASKS

The main objective might be achieved by developing:

- a common delivery and communication system with an user-friendly environment allowing access to the on-line multimedia learning resources;
- an appropriate pedagogical framework for teleteaching facilitating new learning services;
- and course delivery and stimulating both peer to peer and pear to tutor communication;
- a software based technology for course transformation from a traditional mode of delivery to a distance education through telematics networks mode of delivery;
- an adequate credit transfer system adopted for the needs of the NTC and with respect to the European standards;
- a joint set of modules determined as a common core curricula in the participating universities and a common accreditation scheme;
- a common standard for course and other teaching material and software preparation as to facilitate for an easier transition from a traditional type of education to a teleteaching type of education;
- a strict procedure for resource materials filtering and

their organisation in an appropriate data base;

- a procedure for on-going DE monitoring and evaluation based on case studies and «good» DE practice;
- quality standards for teleteaching products and services, and their production and delivery. On the basis of the on-going projects and new developments the first (experimental) teleteaching school year at Sofia University Teleteaching Centre might be offered in 1999. The teleteaching will not replace the traditional type of education but rather make it more flexible, efficient, and cost effective.

5. ADVANTAGES

The main advantages of the NTC are [3,4,5]:

- it provides education and training along with new types of university services, e.g. performance support, partnership, co-operative work, information access, consultancy, etc. on a national and worldwide scale using telematics facilities;
- it defines new roles for universities in their relations to large and small companies who are evolving toward learning organisations. They might jointly develop and deliver appropriate university services to such organisations, using telematics facilities. The NTC will offer services to broader audience:
- staff and students in higher education;
- professionals in organisations who need on-going
- support in order to keep up-to-date with new developments in their fields;
- training departments of organizations;
- enterprises which incorporate the advantages of telematics services.

The NTC might provide a diversity of courses and services and become a facilitator of educational clearing houses, providing learning materials, educational multimedia software and other educational resources both to the networked institutions and other regional organisations and enterprises. The NTC might also help such enterprises in development of their business presence on the Internet.

The NTC offers an opportunity for the universities to participate in a world-wide education and training which can be more profitable by involving new target groups of learners.

6. CONCLUSIONS

A multi-country network of university based teleteaching centres might be established as to cover some of the Phare regional centres but in some cases, depending on the telecommunication facilities which are available, such centres can be established at separate sites, e.g. institutions, big organisations and enterprises, specialised teleteaching units, etc. For the first five-ten years (until the majority of families in the CEE countries have computers and modems at home) the NTC could also provide access to telematics facilities for some students.

Commission II

PREPARING THE CHILDREN TO ENTER A SOCIETY BASED ON KNOWLEDGE: LATIN AMERICAN EXPERIENCE IN THE USE OF MEGA-TOOLS FOR DEVELOPING MEGA-ABILITIES

German Escorcia Saldarriaga

DIRECTOR OF THE LATIN AMERICAN EDUCATION RESEARCH CENTER (MEXICO)

The GENESIS and QUORUM projects sponsored by IBM under the agreements with the governments of some Latin American states proved an initiative which, in the philosophical sense, was designed to deal with a 21st-century task: creating a society resting on global economics and knowledge. This implies the shaping of a new personality model, a higher level of intellectual capacity and new super-abilities, which, in turn, calls for mega-tools and mega-projects.

International competition, the development of human resources and the geographical location of the Latin American countries were the principal strategic factors that in the last years of our century have turned modernization and reform of basic education into the top social priority.

The GENESIS and QUORUM projects were developed by researchers at the Latin American Education Research Center (LAERC) in collaboration with specialists of the Massachusetts Institute of Technologies (Teaching and Epistemology Group), University of Western Florida (Institute of Human Thinking and Artificial Intelligence), Hardford University (Institute of Technical Education), and the Technical Education Research Center (TERC). In addition, a number of Latin American universities and other leading educational establishments gave the project the benefit of their experience and vision of continuous education and raising the level of skills. Among the participants in the project were also Lego (Denmark), LCSI (Canada), IDEA (Spain), and other organizations in the United States, Brazil and Mexico.

Within the framework of the general philosophical approach an attempt was made to identify the key abilities that will be required in the next century, and to define the use of various technologies in the advancement of these abilities. Four mega-abilities were identified:

1. A powerful creative force, an ability for abstraction and critical assessment.
2. Systemic thinking, dynamic change of interpretation and feedback.
3. Continuous education through research, discoveries, the use of the trial and error method, and constructing/designing.
4. Mutual communications, uniting into teams (including virtual ones).

The role of computers and telecommunications as mega-tools far surpasses the ideas and concepts expounded by secondary school courses. They model flexible rational spaces and open up new opportunities for the required transformations. Mega-projects imply the involvement of governments, businessmen, politicians, educators and the public.

This concept was accepted by most private schools and other educational establishments, especially within the framework of the contracts for technological support and unification of services, specifically, by the National and Regional Governments of Costa-Rica, Uruguay, Mexico, Argentina, Colombia, Brazil, Chile, Ecuador, Guatemala, Panama and Venezuela.

After four years of research work in collaboration with the Institute of Human Thinking and Artificial •Intelligence of the University of Western Florida, the QUORUM project covers over 1,000 schools, 10,000 teachers and 1.5 million children in 10 countries; they have access to computer technologies, teaching tools and telecommunications. Within the project framework, a teaching environment «without boundaries» was created for the children's collaboration. Schools in Mexico, Brazil, Venezuela, Costa Rica, Chile and Florida (USA) are currently united by a telecommunication network using the standard local network on school servers, which are hooked up to the regional servers (Vnet and TCP/IP) and Internet.

The main merit of the QUORUM project is that it creates an environment oriented towards creating instead of the environment for consuming information, which is currently offered by Internet-type systems.

Apart from the use of computers to service the traditional subjects on the school curricula drafted within the framework of the existing educational models. GENESIS and QUORUM also offer other opportunities. Specifically, they promote the formation of a new level of responsibility and help teachers, students and the management to acquire practical skills through «New Windows», which can help train the users for work in the conditions of the third millennium. The learning devices, such as «Conceptual Maps» and «Cognitive Capacities», constitute part of the studies within the framework of the QUORUM project and are currently at the stage of development.

Despite the natural limitations inevitably present in the developing countries, the accumulated experience has proved useful for LAERC. It assisted the project heads in achieving the final goal, «putting the most powerful tools in the service of the most promising minds».

TRANSFORMING CURRICULA IN THE TRANSFORMING COUNTRIES: AN EXPERIENCE FROM SLOVAKIA

L'udovít Molnár,
Pavol Návrat

SLOVAK TECHNICAL UNIVERSITY, BRATISLAVA

ABSTRACT

The process of complex political, economical, and social changes in the countries of Central and Eastern Europe involves far reaching transformations. To transform educational contents, form and organization is one of the urgent needs, having in mind the semi-total isolation that lasted nearly half a century. In the paper, historical background of the ongoing transformations of the system of higher education is briefly outlined, with emphasis on analysis of its consequences for the current situation. The transformations must aim not only at overcoming certain weaknesses of the present system, but also cope with new challenges that any curriculum in a discipline developing so swiftly as Informatics is facing today. Approaches taken to transform the Informatics curriculum in Slovakia are discussed. A role of projects for international collaboration is mentioned.

HISTORICAL BACKGROUND

The isolation of Central and Eastern European countries has been most sensitive in areas of economical relations and human contacts. The isolation in economical relations had consequences mainly for the level of technology used in industry and education. No sophisticated equipments were available for education institutions. Moreover, education esspessially at technical universities had to be oriented to technology used in industry. The isolation in human contacts resulted in practical impossibility of taking part in international scientific events such as conferences, common research projects, standardization efforts. The consequences of the above isolation can be found e.g., in a generally lower numbers of publications in international journals, citations, patents. Research and development was therefore more oriented to theoretical, methodological and special technological problems where we have reached relatively good results. In Informatics, this resulted in production of computer equipments in Slovakia, but also in developing own software tools and applications. An analogous situation was in education. Theoretical level and structure of education were good enough what was recognized already at that time. We wish to mention that our graduates were the ones who designed several models of computers that were produced by the local industry. Informatics was introduced already in seventies to secondary education curricula.

NEW CHALLENGES AS CONSEQUENCES OF THE TRANSFORMATIONS

Transforming Central and Eastern European countries towards a civic society with free market economy is a complex task without a precedence in history. Despite that, there have already been achieved enormous results in transforming Slovakia, especially in the economic terms. The process of transforming contents and form of education must keep pace with these changes. Even more, it should be the forerunner of transformations, learning both young and older (here special emphasis should be put on retraining, distance learning etc.) people to understand ideas and concepts many of which were banned for decades. The ideas and concepts are related to various levels of generality. For example, the idea of a university as an environment for free sharing, communicating, and cultivating knowledge is a very general one. It is also a very important one. Slovakia has since 1990 a very liberal higher education law that grants to universities autonomy and full academic liberties. The experience of today's young generation acquired while being at a university is vital for straightening the democratic fundaments of the civic society in Slovakia. One should bear in mind that practically no one else in the productive age has a similar experience in the transforming countries, the teachers not withstanding.

Other important aspect is that the educational process takes place in conditions of an open, or more precisely progressively opening market. Students experience the competitive environment and recognise the role of an individual responsibility in shaping their own personal carriers. Universities are subject to market competition, too. For example, alone in the city of Bratislava, there are three universities offering a study in disciplines related to Informatics. Moreover, there are several other universities offering similar studies within a radius of 200 kilometres (including Brno, Vienna and Budapest) in the three neighborhooding countries. After the fall of the iron curtain, all these have become real options for students from the region, thus creating potentially one of the most competition conditioned regions in Europe. The fall of the iron curtain, geographical location of Slovakia and of Bratislava in particular, has also negative consequences in a brain drain. The brain drain has two forms. First, the classical, is that better conditions for work, most notably higher salaries lead highly educated personal of universities and research institutes to seek work abroad. The second, open market brings many companies to settle in Slovakia. They, as well as an increasing number of local companies are able and willing to pay salaries which are approaching the "western" levels, but which are multiples of average salaries elsewhere. Universities, who are generally underpaid, suffer extremely from this "escape" of their best people.

CONCEPTUAL FRAMEWORK FOR NEW TRANSFORMED CURRICULA

The centuries long European experience of university education is certainly an important source of inspirations for organizing higher education and for designing its contents as well. The very idea of an university as an environment for free sharing, communicating, and cultivating knowledge, which Slovakia shared with others during the whole history of universities in western civilization except during the period of the totalitarian rule, must be revived. This fundamental standpoint, along with their role in studying, maintaining and developing the national heritage, provides the basic conceptual framework for developing curricula for universities in the transforming countries. Our university was one of the first in the country to take part in TEMPUS joint European projects aimed at exchanging educational experience among European universities from both East and West in order to introduce up-to-date know how and technology into curricula. Since 1990, we actively participated in two projects:

- EPICS (Educational Programme In Computer Science), with universities from Great Britain, Spain, and some Central European countries [1],
- Neumann Network, with universities from France, Great Britain and some Central European countries [2].

Essentially, two outcomes of these projects are to be stressed. First, establishing professional and personal links among the institutions and people has added significantly to reestablishing a relatively standard situation within Europe. Second, the projects supported us in building well equipped laboratories where training of students can take place at a level comparable to any standard European university. Building on these outcomes, we have been able to enter into international research collaborations. The personal links and the level of mutual trust and knowing each other proved invaluable e.g., in formulating and successfully solving the research project "Large parallel databases" within the European

Copernicus programme (COST). Here, teams from different institutions collaborated so closely that common results were achieved [3].

It should be noted that the transformation of Slovakia has many facets. The ongoing growth of private enterprises, which can be partly "blamed" for the above mentioned brain drain from the universities, is on the other hand "responsible" for massive increase of utilisation of information technologies. As a consequence, we are witnessing a growing interest of students in studying Informatics.

Despite all the difficulties, lecturers at the universities realise that they must not only achieve results in scientific research, but also maintain industrial links. As an example, software specialists from the Department of Computer Science and Engineering of Slovak Technical University in Bratislava have been collaborating with Slovak Telecom in designing their integrated information system.

COMPLETING TRANSFORMATION

Achieving a "normal" state is a long term goal. On the other hand, in many aspects Slovakia is already now a standard country with a functioning democratic system, including the self-rule of the universities. In fact, it has achieved a respectable level of quality of higher education in many fields. Slovakia's graduates, especially in disciplines not so heavily afflicted by the indoctrination imposed by the former regime, have ever since been able to build successful carriers in free countries. In other words, in most cases Slovak graduates have been able to achieve at least a de *facto* recognition of their higher education diplomas, which can be interpreted as an implicit recognition of their universities' corresponding curricula. Now, the situation calls for a *de iure* accreditation. At the national level, accreditation of universities and of their curricula is a standard requirement that must be met by all universities awarding the particular degree. For example, Slovak Technical University has been accredited by the Accreditation Board to award full range of baccaularate, master and doctoral degrees in Informatics.

While accreditation at the national level is a necessary legal requirement for a Slovak university according to the current legislation, seeking an international accreditation for its particular curriculum is a matter of its serious consideration. On the one hand, confronting own concepts with those of others is a crucial aspect of the openness that is an assumed property of universities almost by definition. On the other hand, meeting the accreditation criteria may be an effort and resource demanding process, so the benefits of the accreditation should be clearly identified.

We at the Slovak Technical University have decided to make the necessary steps towards accrediting our Informatics (Computer Science and Engineering) curriculum internationally at the IEE first. Our reasons are:

- to achieve a higher degree of compatibility of our study programme with those typical in Europe [4],
- to promote introducing several up-to-date subjects into the curriculum which might not be considered as urgently needed yet in Slovakia due to the current situation of still existing underdeveloped industry in certain areas of high technologies, but which are going to become crucial within next few years.

We have already taken several steps towards achieving the stated goals:

- The complete Informatics curriculum is offered not only in Slovak language, but in English as well.
- After at least a decade of concentrated efforts, we have a very comprehensive library with a wide spectrum of international scientific journals, including all the major titles published by ACM and IEEE.

Slovak Technical University has been the first one in Slovakia to graduate last year its students who finished their studies after five years of studying completely all subjects in English. It is very likely that students from abroad, as was the case of these, will form an increasing portion of enrolment seeking an acknowledged quality of education offered in English. The curriculum in Informatics is an excellent example.

CANADA'S SCHOOLNET: BRINGING THE CANADIAN VERSION OF THE INTERNET TO ALL SCHOOLS IN THE COUNTRY

Gerald McConaghy

SCHOOLNET, WINNIPEG (CANADA)

This is a brief description of Canada's SchoolNet, a unique experiment committed to developing content and services on the internet for all of Canada's schools. Besides its pedagogical objectives, SchoolNet hopes to strengthen communications and sharing among teachers who are scattered across the country's ten provinces and two northern territories. SchoolNet can be seen also as a professional development movement designed to help teachers become skilled in using technology in their classrooms. As well, it is a repository of classroom lessons, Canadian in focus, and suitable for use with or without the computer. And at its very heart it has the goal of improving student learning.

Canada is a vast geographical territory, stretching from the Atlantic Ocean in the east to the Pacific Ocean in the west and from the American border in the south through to the northern land territories to Siberia. In contrast to its physical size, its population is quite small. Most of its 27,000,000 people live along a thin geographic line close to its southern border. However, there are scattered towns and communities in all areas of the country. Remote outports and isolated villages exist in its eastern, western and northern extremities. In addition to its disproportionate population density, Canada finds itself with ever increasing cultural differences among its traditional and recent peoples. The disparity of wealth and the distribution of its resources are evident as one travels throughout the country. Further, Canada has many layers of government and individual educational jurisdictions, which do not foster a national education focus. Yet, both in spite of and because of the Canadian diversities and complexities, the SchoolNet project has been created.

In 1993, SchoolNet began as an experiment among a few schools, a federal government department (Industry Canada) and a telecommunications consortium. The experiment was so successful that by late fall of that year, 1000 schools, located from coast to coast were using SchoolNet services. By 1995, 5000 schools were regular users of SchoolNet. It is now expected that all schools will be connected by 1998. A second experiment was tried. Computer equipment and access to the Internet were provided to a few rural schools, with the agreement that these schools would be open after regular school hours for the use of the community. Through a local co-ordinator, volunteers were recruited to help community members and businesses use the internet. Here, too, the response was enthusiastic. Last year, through joint funding between the federal government and the local community, 300 communities were connected to the information highway. The budget for such connections has been increased and it is projected that many more communities will become internet and SchoolNet users over the next three years.

Despite success of this rural community and business participation, SchoolNet's main focus is education.

SchoolNet is a partnership between various levels of government, the education community and the business community to provide quality services for schools, libraries, colleges, and universities. This vast project is tied together by an organization that has an advisory board made up of about 50 representatives from national education associations, provincial ministries of education, various federal departments, telecommunication and cable companies, and hardware and software companies.

Since education is a provincial responsibility, and provincial governments are quick to respond to any attempt by the federal government to encroach on their domain, SchoolNet ensures that it has the support of the provinces as it develops material for school use. The result is a grass roots organization which decides the net's content, monitors its progress, and evaluates its success. For instance, it has a number of subcommittees, made up of representatives from various provinces, associations and ministries, One of these is the Content and Services Committee which is responsible for advising as to the types of products that should be developed and does so, based on consultation with clients through focus groups and questionnaires.

Consultation with teachers indicates that they want educational materials which can be of direct help to them in their teaching, using or not using the internet. They also want to be able to communicate with other teachers across the country about lesson plans, teaching methodologies, etc. SchoolNet has set about trying to develop these kinds of services. Teachers who are active users of technology are encouraged to share their ideas and materials they have developed for use in their classrooms. As a way to stimulate the creation of teacher made products, SchoolNet pays $300 to any teacher who has material which can be put on SchoolNet for other teachers to use. It is expected that through this initiative a 1000 quality projects a year will be produced for the next three years.

More significant amounts of funding are also made available to schools and other organizations, profit or non-profit, to develop internet products. Each month SchoolNet receives and reviews proposals for developing products which will have educational value to schools. Four criteria are used to judge each submission:

- originality (is there anything comparable on the Internet?) ;
- sustainability (can the product be sustained by funding other than through Industry Canada after the first year?);
- audience (does the product have potential users across the country?);
- partnership (are there partners who support and will be involved in helping to ensure the success of the product?). The SchoolNet site at Carleton University

(http://www.schoolnet2.carleton.ca) is at present the repository for the products developed. Teachers can browse there and can get information on a range of topics. There are hyper links to web sites in North America and around the world. The menu remains under constant construction in an attempt to make it as user friendly as possible.

Encouraging schools and other interested organizations to develop products for SchoolNet has resulted in a rich stream of new material and services being made available. Each month new products appear on the SchoolNet site which have been developed by Canadians for schools. That does not mean that SchoolNet refuses to have non-Canadian products; there are many from other countries, mainly through hyper links. It does mean that the emphasis is on developing Canadian material for Canadian schools.

Most Canadian schools are not yet well equipped with technology. Many have older computers that browse via the gopher. Products must be developed which can serve these schools, now in the majority. At the same time there is an increasing number of schools who have powerful computers with multi-media capability and access to broader band width. SchoolNet actively seeks products that will be of value to these schools. It is sponsoring a multimedia showcase to be made up of school-generated multimedia projects. When the showcase is completed later this year, it will be put on the internet.

Funding is always an issue in the implementation and evaluation of major innovative projects. Who pays for what? How long will the financial support remain? Is the project fiscally viable? Presently, its funding comes mainly from the federal government through the Department of Industry and has been assured for a four year period from 1995 to 1998. It is mainly seed money as the expectation is that after 1998, SchoolNet will become self sustaining through the sale of some of its products and by corporate sponsorships and participation. Money is leveraged by asking organizations submitting proposals to develop products to contribute a part of the cost and to enter into partnership with others who can help support product development.

SchoolNet's content and services are growing but two important questions have to be addressed. The first is what kind of professional development do teachers need to use on-line resources in the classroom effectively? The second has to with the evaluation which needs to be done to ensure that the products developed are useful as learning tools for teachers and students.

The advisory board recognizes the importance of professional development and is currently exploring ways to deliver this effectively, taking into consideration the regional, linguistic, cultural and geographic differences of Canada. A pilot project is now under way with six urban and suburban school boards in the Ottawa area. With funding from SchoolNet and the school boards they have hired teacher education graduates, who have strong technical skills. They have been given special training to work directly with teachers to help them develop on-line skills and to, adapt their teaching to include resources from the internet. An evaluation of the project is being done. It is hoped that from this experiment a model can be developed which can be used in other urban areas.

Newfoundland, a province at the eastern extremity of the country, large in land mass but sparsely populated, has developed a professional development program suited to teachers in rural and small schools. A "train the trainer" model, one or two teachers from schools with a given area are invited,to a two day initial workshop. There are then a series of on-line units with a final workshop towards the end of the year. These teachers are then asked to work with other teachers in .the school. This model is less expensive than the Ottawa project and allows for greater coverage of teachers. There has been no formal evaluation to date. Informal feedback suggests that it works well in many schools, especially where the teacher who has taken the workshop training is skilled in working with other teachers.

It is recognized that if the internet is going to be used as a tool to improve student learning, teachers will need to know more than how to connect to it, browse and find material. There must be a new conceptualization of teaching and learning (Dede, 1995). The power of the internet will be seriously underused if it is seen only as a way to gather information. Its main benefit comes as a tool which permits teachers and students to create and construct knowledge (Stoddart and Niedhauser, 1992). Technical skills for the teacher are not as important as a thorough knowledge of how students construct their learning. The Internet must be seen and be used as a media allowing maximum interaction between the student and the material selected. Hopefully, the evaluation of the Ottawa project will give some insight as to the content needed in professional development to help teachers adopt a constructivist approach in using the Internet.

The question of effective evaluation is probably the most difficult issue to address. Because of the need to get as many projects on-line as quickly as possible, and the rapidity with which the over 1000 new projects have been coming on stream each month, there has not been careful attention given to evaluation *a priori*. Effective evaluation of both the products and the goals will have to be determined by this same grassroots approach. This is a complicated and long term process.

Teachers teach based on different philosophies and, therefore, will use SchoolNet resources in different ways. Students also have different learning styles. Do all students benefit from interaction with on-line material? Which models of use give students greater learning gains? As well, SchoolNet is not the curriculum but bits and pieces to help enrich it and make it more meaningful to students. What ways are there to evaluate these "value-added" components? Evaluation will likely need to be done through a number of case studies which looks at the context in which the teacher or a number of teachers, using the same philosophy and approach, use SchoolNet resources.

SchoolNet is an emerging organization. It will change in structure as new needs are identified and new ways of meeting them are proposed. It is presently examining how it can develop distributed or regional systems, allowing it to respond to needs identified in a various region or by a specific group such as the native community. It is also interested in collaborating with other countries as it and they try to develop valuable on-line content and services for students and teachers.

Commission III

THE POLICY OF INFORMATIZATION OF EDUCATION IN AFRICAN COUNTRIES

Mushobekwa Kalimba Wa Katana

MINISTER OF HIGHER EDUCATION
AND SCIENTIFIC RESEARCH
(ZAIRE)

Mister President,
Dear Colleagues,

I have the honour and pleasure to speak before the colleagues who are attending the meeting within the framework of Commission Three: the use of NIT in education: policy and co-operation.

At the present time one cannot neglect the connection between new information technologies and education. In 1989 on the initiative of France and the former Soviet Union UNESCO organized the First International Congress in Paris with the support of the interstate Programme on Informatics, the main subject being the trend towards «promotion of international co-operation». At the Congress some recommendations were formulated and some supposed top priority tasks were defined. These recommendations were mainly aimed at getting some advantage from a collective experiment and pooling limited resources in the area of new information technologies in education and consolidation of international co-operation in the field.

The main subject of the Second International Congress which is now taking place in Moscow is «The Educational policies and New Technologies». To prepare for the Congress experts from African countries had a meeting in Dakar in April 1996. Some recommendations were formulated as a result of their work. Special attention should be paid to the three recommendations given below:

«The commission of experts recommends the member-states of Africa to support the efforts on the introduction of new pedagogical technologies including the use of new information technologies in conformity with the approved policy which is presented in specific acts».

«This commission strongly recommends for each member-states to work out and to use the national plan for the development of informatics, particularly what concerns applications which are used as a means of education».

«Teaching informatics of the teaching staff should be in the foreground when introducing new technologies in education».

After considering these recommendations one can come to the following conclusions:

- *almost a total lack of approved policy which is to be presented in specific acts on using NIT in educational systems of the countries' subregion;*
- *almost a total lack of national plans and necessary means which could facilitate the introduction of NIT, as well as an insufficient training of the staff who cannot shoulder these new responsibilities.*

Some countries carried out experiments with national plans. The results were mostly satisfactory. However, there are certain difficulties, which are mainly due to the lack of man-power and financial resources.

The purpose of this report is to share some thoughts about the working-out of the national and regional policy concerning the introduction of NIT in educational systems; in this report these issues are considered in the four directions, started below:

The urgent need of national plan.
Stages in working-out of the national plan.
Mobilization of recourses and co-operation.
Conclusion.

1. THE URGENT NEED OF THE NATIONAL PLAN

It is quite obvious that when working out the national plan on the introduction of NIT in education the profitableness and success cannot be clearly defined. In reality, the introduction of NIT in education in conformity with the national plan could enable:

1. to define national priorities;

2. to avoid non-synchronized and «wild» introduction of NIT, which would result in wasting of man-power, material and financial resources and also time...

3. to ensure the efficient introduction of NIT.

II. STAGES IN WORKING-OUT OF THE NATIONAL PLAN

The working-out of the national plan is done in stages. In accordance with the national plan on introduction of NIT in education the following stages could be suggested:

1. The search for people who may be interested in the subject at all levels

At this stage the work is done to find out people who can set specific tasks and to involve them in the solution of these tasks.

2. The organization of the working group

To organize the working group including those who set tasks, specialists and any other people who are interested in the solution of the problem.

3. The immediate working-out of the national plan on the introduction of NIT in education.

3.1. *School curricula.*

1st step: organization of the working group;

2nd step: working-out of school curricula as a series of consecutive blocks.

3rd step: working out of school text-books in accordance with the approved curricula.

3.2. *Training of teachers and other specialists.* First of all thus training is intended for the main group of high level professionals in the field of education. This main group in its turn is to prepare teachers who must be able to introduce new programmes in education process and use new text-books.

Parallel to the training of the main group high level specialists the training of another group of high level specialists is to be organized to create software for education purposes, to work out concepts, to set up data bases and to install infoware, and also specialists in telecommunication and information networks. These specialists will be able to integrate all new information technologies.

3.3. *Acquisition and use of the equipment*

Short-term tasks

Organization of commission for working out of curricula and school-books.

Working out of curricula.

Working out of school-books.

Medium-term tasks

Acquisition and introduction of the equipment.

Adaptation and working out of software.

Training of teachers and technical personnel.

Gradual introduction of NIT in schools.

Creation of data banks containing school data.

Long-term tasks

Creation of data banks on main fields of national life.

Setting up and reconstruction of schools (school infrastructures).

III. MOBILISATION OF RESOURCES AND CO-OPERATION

The national plan of introducing of informatics into education can be carried out with success only in case of mobilisation of human and financial resources.

Nowadays many African countries have serious social and economical problems. These conditions reduce their ability to solve problems in education.

Mr. Colin Power, the assistant UNESCO director of education, emphasised the fact, that the African countries allocate from 38 to 200 dollars on education of one child, while the developed countries allocate from 2000 to 9000 dollars.

In spite of these conditions our governments understand the importance of the problem and do all they could to allocate enough money to accept the challenge. These efforts should unite formal and informal education and increase technological culture.

We should call upon international community to increase their efforts in this very field to make the gap between developed countries and other countries not so huge.

Two-sided and multi-sided co-operation, regarded as a supplement to the efforts of countries and regions, will be appreciated.

Nevertheless, UNESCO should be a catalyst and a co-ordinator of these resources.

African countries should not forget about their responsibility to unite regional and subregional resources for realisation of their projects.

We think that there are some other methods of promoting of NIT introduction in our educational systems by African countries themselves.

IV. CONCLUSION

Is it proper time now to work out the national plan on introduction of NIT into education?

Can we define the main stages in the process of working out?

Is the mobilization of recourses the main factor in the successful realization of this project?

How can we mobilize these resources?

Such are the questions which I put to you, and which you can consider.

I wish that a result of this consideration the measures could be defined that would enable our countries to solve the problems which still arise when introducing NIT in education.

Thank you.

Further we shall try to describe briefly the problems which arise when NIT are introduced in education.

I. THE MEANS OF INTRODUCTION OF NIT IN EDUCATION

1.If it is necessary then all kinds of education regarded as parts of private education, are tested to determine the profitability of these kinds of educational activities, which are to meet the demands of the users who directly use NIT.

2. NIT were mostly used in the systems of formal education to realize education using computers, for instance, in the field of medicine. It should be noted, that institutions of higher education are increasingly interested in using NIT in teaching and research activities.

More and more teachers working in the field of higher education acquire a lot of experience in using NIT. Pedagogics is also taking interest in NIT, which are *used in research connected with education and in training teachers. Some higher educational institutions are working out programmes for the distant training of teachers despite a low technological level. Special studies on the technology of education are carried out at some higher educational institutions. The increasing number of students regard didactic materials as an obligatory subject.*

3. Besides higher education, tele-education and radio education have also been tested at different levels of education. Taking into account that the number of teachers is not enough, some countries have investigated the possibilities offered by the radio and television to ensure the access to school education for the maximum possible number of children who live in remote areas.

4.The cost of hardware may often have been the impediment in the introduction of informatics in primary and secondary education. However, even in these areas of education private schools offer curricula which include using NIT.

5.Among possible ways of getting education numerous courses on primary education and teacher training according to modem requirements give you a chance to choose. These courses mainly aim at training teachers to use NIT in their professional sphere. In connection with this UNESCO/BREDA organized a great number of demonstration lessons. Even if the positive effect of these courses seems to be rather weak, however this training contributed to the acquisition by the teachers of the fundamentals of informatics. It is important to emphasize the need to exchange teachers from different countries, specializing in the field of informatics.

6.This is the grand total on the place informatics takes in African educational systems. Nowadays it is important that we should advance and work out new strategies taking into consideration the limitations mentioned above.

II. THE MAIN PROBLEMS

7. On the whole, African countries admit and appreciate the importance and the role of NIT in education. However, in our opinion, the use of NIT in education presupposes the necessity to solve some problems.

8. First of all, the initial difficulty is connected with labour resources and equipment, which are the main factors in using NIT. As far as labour recourses are concerned, the main difficulty lies in teacher training. In fact, only a small number of teachers in a small number of institutions were really welt trained to be able to use new technologies in education. Another difficulty is connected with an insufficient number of teachers who specialized in didactic materials in general and in using computers in particular.

9.Concerning the problem of material recourses, it should be mentioned, that the programmes of structural settlement make it possible to economize in difficult situations in some countries, simultaneously creating difficulties in acquisition of the equipment which is necessary, when introduction NIT in educational systems.

10.Apart from that, the problem of software arises. Sometimes the software which is available in the market cannot be adapted to the cultural context of a young African. Didactic materials, which can be used in education, are often imported products and are insufficiently adapted to (he school realities of the continent. Taking into account all these reasons, the governments should work out a reasonable policy that could enable to make NIT contribute to the development of their countries and the continent.

11. Imperfect basic infrastructures constitute another difficulty in introducing NIT in education. For example, electrification and telecommunications are almost completely absent in a great number of countries. This is the weak point and the situation can be improved if the competence of African specialists in the field of technology is increased. In some cases there is an impression that the level of technological competence change in opposite directions: where the adequate and sophisticated equipment is used, the personnel make mistakes, it is not numerous or efficient...

12. These problems result in the need to solve the question of support for software and hardware, .because NIT require specialists who look after software and hardware. In many countries the tack of support can be regarded as one of the major obstacles in the technological development of the continent.

13. Some critical remarks can be addressed to the manufacturers of the equipment. In fact, the equipment that is available in the market is often designed and realized not taking into account the peculiarities of the continent, especially parameters on dust and humidity in African climates.

14.It seems that among all the difficulties the main obstacle is the lack of national policy on the introduction of NIT in African educational systems.

15.Obviously, the solution of these numerous problems when introducing and using NIT in African educational systems, would enable the continent to approach the 21st century.

III. COOPERATION

IV. PARTICIPANTS

Interafrican Cooperation

17. The mechanism of this co-operation is gradually taking form with the help of regional and subregional initiatives.

The original is presented In French

INFORMATION TECHNOLOGY IN NEW ZEALAND SCHOOLS

Don Ferguson

SENIOR POLICY ANALYST
MINISTRY OF EDUCATION WELLINGTON
(NEWZELAND)

SUMMARY

In common with the rest of the developed world, uses of information technology in education in New Zealand have focussed in three broad areas:
educational administration;
the "ordinary" classroom;
facilitation of distance/open learning opportunities.

The most recent survey undertaken by New Zealand Telecom in late 1995 reported that there was one computer per 18 students in primary school and one computer per 10 students in secondary schools. Half of the computers in the schools were more than three years old. Statistics from a Ministry of Education survey show that there is a ratio of one computer per 15 students and that a high proportion of schools have one or more CD-Rom drives.

EDUCATIONAL ADMINISTRATION

The most up-to-date information available suggests that all tertiary institutions and secondary schools, and almost all primary schools, are using computer technology to facilitate elements of their administrative or office procedures.

Observers in the field report that all schools routinely use word processing software and spreadsheets for administrative purposes. More than 97 % make extensive use of facsimile and an increasing number make use of e-mail. Many use sophisticated software publishing programmes to develop news sheets for communication with their communities.

Primary schools are using a variety of data file-handling computer programmes to record and process roll, class, and pupil details. Various programmes are used to record and process financial and asset records.

Secondary schools use a variety of software applications (from fully integrated relational data bases to suites of separate packages) to record and process for example: timetable; roll; class; and pupil details; achievement profiles and records; and Financial and asset management information.

The Schools Electronic Network was originally established to improve information flows between schools and the Ministry of Education.

THE «ORDINARY» CLASSROOM CURRICULUM

Computers have been used in New Zealand schools for a variety of teaching and learning purposes since the 1970's. In primary schools most computers are located in individual classrooms while in secondary schools traditionally computers have been located together in computer labs. However, today there is. an increasing tendency to locate some of the computers in classrooms dedicated to particular subject areas, i.e. in the science area for data logging exercises; in the graphics area for computer-aided drawing. Information technology is considered important in the classroom for three fundamental (not necessarily exclusive) reasons:

• information technology as a tool for learning;

• as an aspect of modem life information technology needs to be learned about in its own right;

• information technology to enhance the delivery" or the learning of the traditional curriculum.

A TOOL FOR LEARNING

The most widespread applications in classroom learning are productivity tools. Word processing and publication programmes are very commonly used in the learning and practising of written composition, especially in primary schools; spreadsheets, and data analysis and presentation programmes are often used in numerically rich curriculum areas such as science and maths; data file programmes are often used in situations where students are developing classification skills such as in social sciences. Various kinds of computer aided drawing programmes are used in art, music and technical subjects.

Since the mid 1980s an increasing number of schools have been using e-mail to communicate with other schools and educational institutions. Some schools are also linked to the National Library and the New Zealand Bibliographic network. Today approximately 61 % of secondary schools and 39 % of primary schools report using on-line services. A small number of schools have full access to Internet and World Wide Web but costs of access are preventing other schools from making use of this service.

A number of educational computing applications that might be called "virtual learning environments" have proved useful in New Zealand classrooms and overseas. This genre of software includes simulations such as virtual laboratories and problem solving/decision making "games" which require students to apply thinking, communication, decision making, or mathematical skills relevant to their current area of learning.

LEARNING ABOUT INFORMATION TECHNOLOGIES

The need for students to become confident and competent users of information technology has been a motivation in most schools' decisions to introduce computers into classroom programmes. While in the 1980s computer awareness was an explicit rationale for computing courses today most schools have seen the development of computer awareness as an implicit rationale, that is a goal which will be achieved as a byproduct of achieving more directly curriculum related benefits.

While in earlier computing courses the teaching and learning of computer programming was an important aspect today most courses now concentrate on the use of application software for problem solving.

Some schools have also introduced students to the idea of computer control by interfacing computers to electromechanical (robotics) devices. Given a particular problem students design and then build appropriate devices and write computer programmes to control the devices in solving the specified problem.

COMPUTER AIDED LEARNING/COMPUTER MANAGED LEARNING

A number of educational institutions have used computer aided instruction and computer managed learning programmes. Some programmes are particularly engaging and students enjoy using them (particularly relative to "ordinary" classroom experiences). However, there is little evidence that the use of this kind of software produces better learning gains than "ordinary" classroom experience. The programmes have been most successful with students of lower ability or with students who have specific skills in need of redemption and which can be improved by repeated practice.

DISTANCE EDUCATION/OPEN LEARNING

New Zealand has a long history of successful provision of distance learning. Correspondence education was initially stimulated by difficulties of conventional school access for children in geographically remote locations. The clientele for distance education now spans primary, secondary and adult students with diverse reasons for not attending conventional institutions. Additionally many secondary school students who are enrolled in "ordinary" schools use distance education programmes delivered by The Correspondence School to study subjects which are not available at their schools.

At the tertiary level two universities offer distance education courses and the polytechnics have been active in providing a wide range of distance education courses.

In 1985 more than 70,000 students were enrolled in distance education courses.

Distance education in New Zealand has embraced the use of broadcast radio, telephone services and the use of 0800 numbers, broadcast television and recently satellite television, desk top video, delivery of audio and videotape materials, and computer disk based materials, including CD Roms.

The use of electronic mail and bulletin boards and audiographic networks is now an important aspect of distance education, particularly in rural areas in New Zealand. This has resulted in an increasing number of telephone lines coming into schools. Most primary schools, except small primary schools, have two or more lines and secondary schools have three or more lines.

TEACHER DEVELOPMENT IN THE USE OF INFORMATION TECHNOLOGIES

A major emphasis in New Zealand over the last six years has been the training of teachers to use new information and communication technologies effectively in the classroom. Over that period the Government has committed over $5.0 million to teacher training in the use of IT and more than 8000 teachers have received school-based training. These teacher development courses have been evaluated by independent researchers who have provided feedback to the Ministry of Education on how successful the programmes were in providing effective training for teachers. These teachers are now confident and competent users of technology in their classrooms and are often involved with assisting other teachers to be more effective users of technology. In The Correspondence School is the sole provider of distance education for primary and secondary school students in New Zealand.

Addition most trainee teachers in Colleges of Education undertake training in the use of information and communication technologies.

The snowball effect of this group of teachers growing ever larger as they share their skills with others is leading to a leaching force who are, more and more, making effective use of technologies in the classroom. However technology is changing at a rapid rate and teachers are having difficulty in keeping up with the advances, e.g., use of Internet. A further problem is that teachers skilled in the use of information technologies are actively recruited by industry.

FUNDING OF INFORMATION TECHNOLOGY IN SCHOOLS

Up until the end of 1989 almost all computer equipment in schools had been financed by parent contributions or community fundraising schemes to the value of about $60 million. Although there is no conclusive evidence available it is reckoned that most of the further $55 million worth of computing equipment placed in schools since the review of educational administration in 1989 has also been financed directly by parents or local communities. Since 1989 schools have been bulk funded for operations and schools have been able to use funding from their Operations Grant to purchase information technology equipment. Rural schools have also been able to obtain funding through a proposals pool for innovative curriculum delivery.

As a rule of thumb it is generally held that a sum equivalent to about 40 % of initial capital cost should be budgeted annually for: costs of software and consumables such as paper or floppy disks, line usage, maintenance costs, and for provision for replacement. On this basis schools should be budgeting about $46 million annually to cover the ongoing costs generated by the currently installed equipment. No Figures are available about what schools actually budget for these costs. However over the last two years many schools have realised the need to budget in this area and an increasing number have information technology plans. Recently the Ministry of Education put out a planning kit to help individual schools develop an information technology plan for their school.

Government initiatives in the information technology area have been focussed mainly on teacher development and on providing seeding funding for pilot projects such as the use of audiographics, development of CD-Roms, use of satellite television, desk top video conferencing, schools electronic network, and exploratory studies in educational computing.

CURRENT AND RECENT INFORMATION AND TELE-COMMUNICATION TECHNOLOGY PROJECTS

Development of interactive CD-ROMS

The Ministry of Education contracted The Correspondence School in 1993 to produce interactive CD-ROM's - one in beginning Japanese and one in translation geometry. (This was at a time before there were any commercial developers of CD-Roms in New Zealand.) These were trailed in schools and are being used in distance education courses. A more extensive CD-Rom in Japanese is currently being developed.

Electronic Network Linking Schools

The Ministry of Education has a text-based network the *Schools Electronic Network* linking approximately 500 schools and with approximately 4000 active users. Over the next few years this network will be expanded to eventually link all primary and secondary schools. The network includes bulletin boards and electronic conferencing facilities. New Zealand Telecom also has an educational network. *New Zealand On Line.* to which about 500 schools are linked, and Massey University has a smaller educational network linking about 200 schools. In all nearly one half of New Zealand schools are connected to electronic networks.

Audiographics for Rural Schools

Over 60 schools are connected in various clusters via audiographic networks. This enables teachers in schools to have classes spanning several schools. Over 20 subjects are delivered in this way. Funding ha:, recently been made available to further rural schools to implement this technology and so be able to offer students a wider range of courses.

Desk Top Video

Two remote schools and one city school were linked to The Correspondence School for this project. Courses in languages and social sciences were delivered to students. Both teachers and students were enthusiastic about the potential of *desk* top video for delivery of teaching and learning to small groups. At the time of the trial it was considered that until costs of hardware and software became more reasonable this technology was beyond most schools budgets. Since this trial some schools have been using the See You See Me product (slow scan video) and report favourably on its use.

Satellite TV Delivery of Educational Programmes

In 1995 the Ministry of Education contracted The Correspondence School to undertake a pilot study in the delivery of languages and technology education via satellite. There are 90 official trial schools and 30 other schools who receive the broadcasts. Programmes in three languages and technology are broadcast daily. This is the first use of satellite delivered TV in New Zealand by any institution or commercial organisation. To date the trial is going very well.

Use of World Wide Web (Internet) for the Delivery of Educational Materials and Programmes

The Ministry of Education has home pages on World Wide Web (http://www.govt. nz/ps/mi.n/edu/) where information about curriculum and administration is available. A trial is being undertaken with ten schools to determine the viability of using World Wide Web as a replacement for the text-based schools electronic network mentioned earlier. It is estimated that currently approximately 100 schools access World Wide Web through a commercial provider.

FUTURE DIRECTIONS

TECHNOLOGICAL ADVANCES

The rate of increase in the number of possible applications of computers has been as rapid as the change in computing technology itself. Developments in multimedia which enable users, in an interactive way, to access text. sound, still and video pictures, potentially provide a number of rich learning opportunities. The rapid growth of the Internet and the resulting access to vast amounts of information, to international discussion groups, and access to up-to-the minute research provides exciting learning opportunities for students. As "broad band" technologies become available these technologies have great potential for facilitating educational interactions between students and learning materials, and between students at physically remote locations. Technologies such as video conferencing and Internet provide an infrastructure for more open learning opportunities.

Educational outcomes

A great deal of the literature on the use of information technology in education reports on: the enthusiasm and engagement of students; the changed but important role of the' teacher; the apparently enhanced role of the teacher; greater productivity; and enhanced co-operation between students. These findings are important because the changes in learning behaviours which students exhibit when using computers appropriately, are strong indicators that enhanced achievement will result. Papert in *The Children's Machine,* explains that the extension to human capability conferred by modem information technology changes the nature of knowledge itself. The fundamental questions of learning are no longer "what?" but "how?" "why?" and "how do I know?" Access to information has the potential to change the role of the learner from just seeker of answers to asked of more questions. Recently schools have been set up whose curriculum is supported by an information technology-rich learning environment. While it is too soon to say what the long term effects of such schooling are interim conclusions are positive. It is important to observe such experiments.

A further issue is whether in fact developments in information technology will make schooling less relevant and students of the future may learn from home, or other community institutions such as the library, using information technologies. This perspective ignores some of the important outcomes of schooling including socialisation. While some students may prefer to learn in this way it is still considered in New Zealand that in the foreseeable future most students will still attend schools. However, advances in technology will change the role of the teacher and of the school. In some curriculum areas students will learn mainly through information technology and in other areas through more traditional teaching methods. Information technologies will generally support and enhance the work of teachers.

Funding

Two particular thrusts are being considered by Government in New Zealand: provision of one computer per five students in schools and secondly to ensure all schools have Internet access. The costs of providing a ratio of one computer per five students together with on going maintenance software and replacement cost have been provided to Government and are Still being considered by Government. With regard to Internet access some clusters of schools are organising joint purchasing arrangements with providers, but this is moving slowly because of the high costs of Internet access in New Zealand.

Principles

Whatever possible roles are considered for government, whether that be intervention strategies, or support for research or development projects, it is proposed that the following principles be adapted as a basis for future decision making.

Information technologies should he considered for use in education only if there is good reason to believe that they will:

- increase student choice; and/or
- increase access to learning opportunities; and/or
- provide enhanced learning opportunity, and/or
- increase the productivity of students: and/or
- provide unique opportunities to learn IT skills.

CONCLUSION

The past six years has been a time of great change in New Zealand education. A new administrative structure has been put in place and major curriculum reforms, involving the total curriculum, are now more than half completed.

The importance of including technology as an essential area in the curriculum has been recognised as has the need for students to be able to access and use information and communications technologies for a range of purposes. Government has accorded in-service professional development programmes for teachers a priority. A range of initiatives are underway for ensuring that teachers are confident and competent users of technology; in encouraging the use of new information technologies in the classroom, and for distance education and open learning. Some of the initiatives, it is hoped, will be a catalyst to encourage schools to undertake further initiatives. As evaluations of these initiatives are undertaken these will give an indication of where future funding is best directed in terms of the use of new technologies for enhancing teaching and learning.

Exciting developments are occurring in information and telecommunications technologies. The potential of these technologies to support and enhance teaching and to provide new and exciting approaches to learning for students is being recognised by Governments' world-wide, particularly as part of wider social and economic reforms designed to increase productivity and competitiveness.

Theme 6

INTERNATIONAL CO-OPERATION

PLENARY

UNESCO INTERGOVERNMENTAL PROGRAMMES IN THE FIELD OF COMMUNICATION INFORMATION AND INFORMATICS

Henrikas Yushkiavitshus

ASSITANT DIRECTOR-GEERAL FOR COMMUNICATION, INFORMATION AND INFORMATICS OF UNESCO

Mr President,

Distinguished Delegates, Ladies and Gentlement!

I am grateful for the opportunity to address this Congress which has brought together such an impressive number of decision-makers, educators, informatics specialists and representatives of governmental and non-governmental organizations from all over the world.

My colleagues and I have been following with great interest the deliberations that have taken place here since Monday and are impressed with the scope and depth of the debate. Now that the different specific aspects of the main theme have been analysed, the topic of international cooperation gives me an opportunity to present it, as seen by UNESCO, in more general terms and in the broader context of the emerging Information Society, of which both informatics and education are major building blocks.

There is no doubt that economic and commercial interests are the main driving force for the building of information highways. However, it is also obvious that the development of education, culture and science, as distinct and integral parts of our civilization, cannot be left totally to market forces. Information highways must not simply provide new and more powerful channels for electronic consumption. They must have large spaces for knowledge and value sharing, artistic creation and public debate.

From the outset, it is important to understand the nature of the relationship between education and training on the one hand, and the information revolution on the other. While education and training are certainly essential for accessing and mastering new information and communication technologies, these techologies must in turn be used to solve today's critical problems of education, particularly in developing countries.

The sad reality of today is that information-wise, just like with regard to economic wealth, the world is divided into "haves" and "have-nots". The industrialized countries have an overwheiming lead in technological advances, while for a great number of developing nations even "old" technologies, like television, telephone or even electricity, are still only a dream. However, a closer look reveals that the new information and communication technologies offer immense opportunities to all societies and individuals for alternative, truly universal and often cheaper ways of accessing and disseminating information.

The concerns of developing countries regarding their participation in the Information Society bear less on whether it should be accorded high priority, than on how to effectively apply information technologies to development so as to reduce, rather than widen and deepen the gap between "haves" and "have-nots" and worsen inequality across the technological divide.

Whether humanity as a whole is to benefit from these opportunities will depend not only on the transfer of technology, but first and foremost on enhancing human capability to make the best possible use of information technology In this context, the importance of education and learning cannot be overestimated. The emerging Information Society, based on the rapid development of information and communication technologies, is changing radically the learning needs of humanity and the traditional perception of education The key word in describing and understanding tins phenomenon is "acceleration". It took humanity over two million years to invent printing, another five hundred to offer itself the first computers, and only 3 to 4 decades to come up with lap-tops, cellular telephones and direct satellite communication. Nowadays, practically every year brings a new technological breakthrough.

In this context, learning is, more than ever, the mechanism through which human beings cope with and in turn contribute to change. The very pace of change and consequently the volume of ever more diverse knowledge and skills required make it impossible to "squeeze" them into several years of traditional schooling. Learning is increasingly becoming *a lifelong* requirement, rather than a mere preparation at the early stages of one's life. The possibility to engage in learning throughout one's life is thus essential for survival as well as a condition for continual quality of life. Without such a possibility, and the will to use it. individuals and whole communities risk to be excluded from the Information Society of tomorrow.

Regretfully, these new learning needs remain, to a varying extent, unmet throughout the world. That is not new: humanity has known unmet learning needs as long as education has been a conscious concern of societies. What is new now is that such unmet learning needs can no longer be seen as isolated phenomena within the boundaries of particular countries or distinct parts of the world, because the emerging Information Society will inevitably be a global society.

But what is the global reality? As we approach the end of the second millennium, there are still some 900 million illiterate people in the world. New illiterates are created every day as the result of inadequate school systems and insufficient conditions to prevent relapse into illiteracy once people have become literate. About 130 million school-age children world-wide do not go to school. Millions of those who do go to school often end up with learning achievements that do not correspond to their immediate needs, nor guarantee the sustainability of learning throughout their lives.

There are many literacies - and consequently illiteracy's. The inability to read and write is but one form of illiteracy. Technological illiteracy, political illiteracy, intercultural illiteracy, and so many other ways in which people are hindered in their ability to act and reflect upon their environment are just as dangerous. More than ever, there is an acute need to address these problems which in a global society are no longer exclusive problems of specific countries and ministries of education, but rather challenges to humanity as a whole. There is simply no way that one can ignore a billion people.

With regard to the world of work, learning is no longer simply a prerequisite for entry into the labour market. In the past, one used to learn in order to get a job and earn a living. Nowadays it is often insufficient merely to have learned. To be a productive part of society, one needs to be able to continue to learn and to respond to the availability of different job opportunities. Linear career paths are being replaced by career networks in which people might explore totally different environments and move in entirely different directions at various stages of their lives.

Furthermore, since labour is no longer a scarce resource, human beings spend on average less time on job-related activities and more time doing other things. Quality of life is thus less a function of self-realization in the formal work environment. It is increasingly related to how people are prepared for the world of non-work. Learning is thus a pervasive aspect of life itself. Both as a condition of survival and as a determinant of quality of life, learning is a basic human right.

The technological development which has posed so many challenges to society is also providing humankind with the means to adjust to the new conditions it has itself created.

In the field of education, information technologies can complement traditional educational techniques and enable education systems to adapt to the different learning and training needs of societies. Computer simulation, telematics and teleconferencing, alongside educational TV or radio, have great potential to reach larger audiences than the traditional classroom process, and to make learning more effective, attractive and stimulating. The increasing variety of interactive media (e.g. compact disks and interactive TV) enlarges the scope and possibilities of self-directed learning. These tools provide an unparalleled opportunity for "reaching the unrelated" and for making lifelong education for all feasible, particularly for learners for whom access is limited by time and space, age, socio-cultural environment, work schedules and physical or mental handicaps. This does not mean, however, that people will spontaneously seize the emerging opportunities to learn, nor does it mean that for those who do, learning will automatically become a less demanding activity. The traditional educational environment will be increasingly transformed into open learning environments characterized by: accessibility, flexibility and interactivity. In these new environments, the roles of both learners and teachers will change significantly. Learners will have to take greater responsibility for their learning, while the role of teachers will be increasingly that of mentor and guide, rather than a mere information dispenser. Most importantly, the new learning environments must ensure dialogue - the main factor in effective learning - both among learners and between learners and sources of learning.

While the traditional school will no doubt continue to exist, the processes taking place within its walls will gradually change. In conjunction with the family environment, society at large, and the media, schools will play a crucial role in preparing new generations for lifelong learning, which itself will take place largely outside the school. Beyond school, people will learn at home, in the work place, in different community settings, using their acquired capacity for self-directed learning as well as the organizational facilities and resources provided by the learning society, a concept which overlays that of the information society.

The use of new technologies raises a number of social, economic, cultural and ethical issues. For example, information technologies and products originate primarily in the developed world. The content of the messages they carry typically reflects the values and interests of that world and the linguistic options are limited to several major languages. This is seen by many developing countries as a threat to local customs, values and beliefs. It is, therefore, important, while promoting the use of information technologies in education, to ensure the preservation of linguistic and cultural diversity.

No country or even group of countries can hope to solve, single-handed, problems related to education and the Information Society. International cooperation in this area is thus a necessity and UNESCO is aspiring to contribute to this cooperation.

Under its very Constitution, UNESCO is required to contribute to "advancing the mutual knowledge and understanding of peoples, thorough all means of mass communication", "promote the free flow of ideas by word and image", to "maintain, increase and diffuse knowledge", and to "give fresh impulse to popular education and to the spread of culture".

With the advent of the information age, these tasks have not only retained their relevance but have taken on a new urgency and UNESCO must seek appropriate responses adapted to the new technological environment. As the distinction between different forms of information and the way in which they are transmitted begin to blur, the principle of the "free flow *of* information" - which until recently had been considered only in terms of mass media - must be extended to include all types of information needed for the advancement of education, science, culture, peace and democracy.

These tendencies and challenges are at the heart of debate within UNESCO and its governing bodies. Thus at the twenty-eighth session of the General Conference of UNESCO last November, a special joint meeting of all the programme commissions analysed "Educational, scientific and cultural challenges of the new communication and information technologies". The General Conference stressed the societal problems of information technologies and the need to:

a) ensure that the rapid development of the new communication technologies is properly and comprehensively assessed through interdisciplinary and intersectional reflection to determine their role as a factor of development;

b) initiate a wide-ranging discussion of the consequences of the development of such technologies for UNESCO's programmes in order to ensure that the Organization is able to anticipate and adapt to these changes;

c) reaffirm UNESCO's ethical mission and contribute to harmonious development of these technologies while ensuring respect for linguistic and cultural pluralism and for the right to privacy;

d) prepare, together with the various partners concerned, specific projects, in particular in the fields of distance education and virtual libraries.

Taking account of the results of the consultative process and the directives of UNESCO's governing bodies, a policy paper, entitled "UNESCO and Information Society for All" has been prepared and some of you have already read it.

UNESCO's recent activities in this area have aimed at widening and deepening international dialogue and at testing various initiatives through pilot projects and activities. Let me briefly mention some of these activities and cooperation modalities.

An important factor in UNESCO's work in this area is collaboration with the International Telecommunication Union based on the cooperation agreement between the two Organizations signed in October 1992. A study carried out jointly by UNESCO and ITU entitled "The Right to Communicate At What Price?" presented a number of strategies and recommendations which together constitute a promising approach to ensuring access to telematics facilities at affordable cost to users in development-oriented sectors.

UNESCO is also cooperating with the study groups set up by the ITU Development Sector to formulate recommendations to strengthen the role of telecommunications in development. It is also participating actively in the work of the United Nations Commission on Science and Technology for Development to prepare a policy report on "Information Technology and Development" for consideration by Member States and UN agencies and programmes.

UNESCO's INFORMATIC programme, launched in 1990, aims at helping African countries to introduce informatics in educational systems. The activities consist of training in informatics of teaching staff, management and administrative personnel in education, training of maintenance personnel, and training in the production of educational software with the participation of teachers and computer specialists.

Within the framework of INFORMATIC, UNESCO organized the first international conference and exhibition on "Computer-based automation in developing countries (AUTO-DC '95)" held in May 1995 at Enugu, Nigeria with the participation of 198 experts from various fields such as educators, researchers, computer consultants, computer companies, planners and users.

The Regional Informatics Network for Africa (RINAF) project of UNESCO's Intergovernmental Informatics Programme (IIP) has mobilized more than $ 1 million from several bilateral donors, notably the Government of Italy. Several training courses for African network managers and technicians have been organized and four African countries helped to connect to the Internet. A Strategy meeting and training course were organized in Libreville in April 1996 to plan activities to extend network connectivity to the Central African sub-region. A model information highway project has been initiated in Ghana under the sponsorship of the International Development Research Centre (Canada), the ITU, the UN Economic Commission for Africa and UNESCO. It is designed to improve access to and use of telematics facilities by promoting coordination and capacity-building in the sectors of public concern. A feasibility study has been completed and extra-budgetary support is being sought, including a request to the World Bank's Info Dev programme.

The African Regional Symposium on Telematics for Development was organized in Addis Ababa in April 1995 by the ITU, UNECA, UNESCO and IDRC. The Symposium brought together more than a hundred specialists from actual and potential telematics user organizations, service providers, telecommunication operators, and concerned government agencies as well as representatives of about 20 regional, international and bilateral agencies active in cooperation in this field in Africa. It formulated a number of national and regional strategies which were endorsed in May 1995 by the ECA Conference of Ministers responsible for Economic and Social Development and Planning. The Symposium will serve as a model for similar symposia planned for the Arab States and Latin America and the Caribbean in 1996 and 1997 respectively.

Following the Ministers' recommendations, UNECA, with the collaboration and support of the other sponsors of the Symposium, established a High-Level Working Group on Information and Communication Technologies in Africa which prepared a regional action framework called the African Information Society Initiative (AISI) which was approved by the ECA Conference of Ministers meeting in May 1996. At. the international level, planning and fund-raising are underway for a $ 11.5 million programme entitled "Harnessing Information Technology for Development" - led by UNECA, the World Bank, UNESCO, the ITU and UNCTAD - to help "kickstart" the AISI as part of the UN System-wide Special Initiative on Africa.

A series of UNESCO-ITU pilot projects on Educational Application of Interactive Television is being implemented in India, Mexico and Morocco. These joint projects are designed to test whether this technology can be affordable and appropriate for educational applications in developing countries, and to provide feedback to the ITU standardization process in this area.

The needs of the international scientific community concerning information highways were discussed at the first meeting of the International Advisory Council on Global Scientific Communications - ACOSC (September 1995) and the ICSU-UNESCO Conference of Experts on Electronic Publishing in Science (February 1996) which recommended that UNESCO contribute to the elaboration of a code of conduct for electronic, scholarly scientific publishing and to pilot projects for the establishment of electronic journals in developing countries. The. Physics Action Council (PAC) organized with UNESCO support network training programmes in Ukraine and the Russian Federation, as well as several regional if network strategy consultations for scientists. Networking cooperation is also underway in the area of environment, particularly within the Intergovernmental Oceanographic Commission and the Man and the Biosphere Programme.

A training course on use of the Internet by journalists was organized with UNESCO support at the Symposium on Information Superhighways: What Strategy for Africa? (Dakar, December 1995). Collaboration is underway with the Panafrican News Agency (PANA) in the development of its African Network for Integration and Development (RAPIDE) which will build on cooperation among public and private media and information services in the region to provide news, market data and legal, administrative and cultural information through the Internet in order to promote investment, commerce and development.

In March 1996, an International UNESCO symposium on communication and copyright in the Information Society was organized in cooperation with the Spanish government in Madrid. The creation, dissemination and use of electronic works, with particular attention to the challenges of ensuring access by the public to such works while protecting the moral and economic rights of their creators and producers were discussed. Dialogue and cooperation between legal specialists and information technologists, and also between users and right holders, were seen as important in meeting these challenges. As a follow-up, a series of regional expert meetings will develop practical recommendations on intellectual property rights and on the organization of cultural industries at the national level.

In May 1996, South Africa hosted the Information Society and Development Conference (ISAD) designed as the continuation of the consultation process within the G-7 group with a view to including in this process the developing world. It was recognized that technological infrastructure was the starting point for the building of the Information Society but, in the long run, content and appropriate use of IT were more important. While the private sector should be the main driving force in the construction of the global information infrastructure, end users and the civil society should not be passive recipients of technology but play a central role in the design of applications and infrastructures, so that the development of the information infrastructure is demand-driven and meets the real needs of society at large. In this context, all societal aspects of IT, including ethical and legal questions and the preservation of cultural diversity, were stressed. The participants also emphasised the role of international organizations in harmonizing various approaches at the regional and international levels. UNESCO actively participated in the conference and will be closely involved in its follow-up.

A project proposed for DANIDA and ITU financing envisages the establishment of pilot programmes in four African countries on mobilization and upgrading of information professionals and community library and information centres to provide multiple development-oriented services, making use of appropriate electronic technologies. In Asia and the Pacific, UNESCO's work on rural Community Learning and Resource Centres (CLARCs) will be extended to make appropriate use of information and communication technologies through pilot projects in several countries of the region. The basis for these activities was discussed at a seminar on the role of communities in the information society (South Africa, May 1996) organized with UNESCO support to coincide with the ISAD Conference.

UNESCO is organizing an International Symposium on Ethical, Legal and Societal Aspects of Access to Digital Information in Poitiers, France, in March 1997, in order to lay the basis for enhanced participation in the information revolution of libraries, archives and information centres, as well as of their users.

A world Forum on the Protection of Folklore, to be held in Phuket, Thailand, in April 1997 in conjunction with the World Intellectual Property Organization (WIPO), will consider the role of information and communication technologies in protecting and promoting intangible heritage for cultural development and intercultural exchange.

UNESCO is actively participating in the preparatory work for the diplomatic conference convened by WIPO in December 1996 to adapt intellectual property rights to the information age by adopting a new Protocol to the Berne Convention and possibly a new instrument to upgrade the protection of performers and phonogramme producers. Efforts have centred on preparing consensus on a balance between the interests of authors and producers, copyright owners and public interest, and copyright exporters and importers through participation in major specialized consultations such as that of the European Commission on Copyright and Related Rights on the Threshold of the 21th Century (June 1995) and the Intellectual Property Conference of the Americas (July 1996).

Regional coordination of training is being promoted in the Arab States and in Africa where UNESCO is working to promote the development of common curricula and international cooperative action for the training of planners and technical specialists in networking and application development, taking account of the roles of communication, information and informatics. Close operational links are being established in this context with other concerned international organizations. A Sub-Regional Arab Workshop organized in Cairo in March 1996 on "Designing and Building an Information Highway" is being followed up in training courses planned in Accra and Tunis in 1996 and in Bamako in early 1997.

Since we are in Russia, I am especially pleased to inform you of the launching this month of the STACCIS project (Support for Telematics Applications Cooperation with the Commonwealth of Independent States) in which our Russian counterparts are playing a central role. With more than $ 500,000 received from the Commission of the European Communities, STACCIS will promote, over a period of three years, regional development and East-West cooperation on telematics applications in the key areas of research, education and environment. Each European CIS country involved in the project will develop its own coordinating mechanism consisting of a principal focal body with responsibility for the overall development and promotion of telematics, and a coordinating committee ensuring the participation of specialized institutions in telematics applications.

Furthermore, an agreement has been reached to establish a UNESCO Chair in Informatics at the Moscow Institute of Electronic Engineering.

These regional and thematic international consultations and piloting are part of a worldwide cooperation framework which UNESCO is proposing to consolidate through a world conference on Information, Communication and Development to be held in 1998. This conference will focus particularly on the critical social, cultural, legal and ethical issues concerning development in the Information Society and will provide a forum for all concerned organizations in the search for international consensus. It will naturally involve consolidation and follow-up of the different initiatives which are addressing these issues, including the Second International Congress on Education and Informatics. More specifically, it will provide an opportunity to evaluate the pilot projects being implemented in various parts of the world under the auspices of international instances such as the United Nations system and the G7, and thus to further develop a framework and methodology for concerted international action.

To summarize, a broad framework for international cooperation in the area of information and communication technologies is already in place. UNESCO, like many other international organizations both within and outside the UN system, is very much aware of the challenges posed by the new information and communication technologies. It sees its mission essentially as an ethical one. It strives to make sure, through the widest possible dialogue, consensus-building and promotion of appropriate policies, that account is taken of the educational, scientific and cultural needs of all nations and individuals, thus promoting a genuine symbiosis of cultures based on mutual respect and enrichment.

However, and I would like to say this very clearly, all international efforts in this area can only hope to succeed if they are matched with commitment at the national level. This commitment must not be limited to simple declarations and expression of interest. It implies a serious and responsible re-examination and adjustment of national priorities and policies. Let me give you just one illustration. We often hear from some poorest countries that they have no financial resources to provide even basic education to their population, let alone access to information highways. That is true. But it is also true (and paradoxical !) that these same countries are often the most active arms buyers and, percentage-wise, spend more on arms than the most industrialized nations. That is why I would like to conclude with one very simple message: if we as a global community want to succeed in building a harmonious Information Society, let us, first of all, revise our priorities.

Thank you.

INTERNATIONAL COOPERATION IN OPEN AND DISTANCE LEARNING

Armando Rocha Trindade

INTERNATIONAL COUNCIL FOR DISTANCE EDUCATION

One of the more interesting characteristics of modern societies relates to the increasing role played by information and communication technologies in everyday life; the pervasiveness of the media and the way common citizens can keep abreast of events, news and ideas produced elsewhere and everywhere in the world is an example of the previous statement.

This does not mean that we are involved in a process wherein all man - made physical reality will become immaterial or virtual; but just that most human activities require more and more incorporation of information, of essentially massless nature. Transporting people and material goods, farming, mining, manufacturing, building and food processing still require spending significant amount of energy to transport mass and to reshape or transform matter; individual services demand interpersonal, face-to-face contact, requiring displacement of individuals from one place to another.

Nevertheless, almost no human productive activity can survive without storing, processing and retrieving information. Consequently, there are many products and services which qualify under the general designation of "massless" (weightless) goods. This means they can be conceived, produced and delivered without neither physically or irreversibly transforming raw materials in any visible way nor actually transferring mass from one point to another.

Producing and broadcasting news; auditing or managing businesses; writing books, articles and theses; developing software; playing the stock exchange; doing banking operations; teaching and learning; developing theoretical research; producing many different forms of entertainment; discussing issues and taking decisions — are just so many examples of human activity that can mostly be done just by transferring data digitally between different places.

This is why the expression "Information Society" is becoming more and more frequently used to characterize either the present corpus of tendencies of social organisation or some unknown (and probably still unforseeable) steady-state of the developed societies of the future.

We shall concentrate, in this paper, on just one such recognized tendency: the absolute need to provide lifelong education and training for all citizens of the world, irrespective of the level of technological and economic development of the country they belong to. Professionals need to refresh, to refine or even to reconvert their qualifications in order to match the ever-changing needs of the employment markets; common citizens need to update their basic skills at exactly the same pace as technology keeps invading their day-to-day life. The fabric of society itself will be changing continuously in keeping with the onset of new societal organizations, new daily schedules, new relations between the individual and the community, new ways of using information and communications. Hence, citizens need to keep abreast of all these changes, so as not to drift away from the decision-making process and to maintain their full capacity of intervention in their own societies and in the world at large.

In this context, it is obvious that conventional education and training can not provide adequate responses to the growing needs of literally millions of users; nor traditional ways of learning will be compatible with current jobs, family obligations and distance between residence and school or training centre. Flexibility needs to be an intrinsic part of any type of continuing education, and this includes flexibility of time, of place and of learning contents, so as to fit the diversity of individual situations, needs and degrees of freedom.

Open and distance learning methods have been used for decades to face this problem. From the beginning of the 70's, many educational systems began operating all over the world using this methodology; their basic principle of operation deriving from the postulate that all individuals are able to learn by themselves (if properly motivated), provided the appropriate learning materials are made available to them and a minimum amount of interaction exists between the teaching systems and its users.

All forms of communications are, of course, relevant for the success of this learning regime: mail, telephone, fax, radio, television, audio and video recordings; e-mail, videoconferencing, computer conferencing; multimedia and all kinds of interactive materials. However, the conventional printed word on paper continues to be an essential element for efficient learning.

It is obvious that some kinds of skills and a number of subject matters can not be taught just to an isolated user, studying at home, even if linked to the teaching system by the most sophisticated telecommunications network. In same cases, experimental work can be computer-simulated (as virtual or "dry" laboratories). However, many other kinds of skills can not, or should not, drift away from the actual handling, touching or manipulating reality itself; the same applies to learning abilities of intrinsic interpersonal nature, like the ones required in medicine, psychology and some social sciences. The way out of the dilemma is to mix the distance-learning mode with the necessary amount of presencial activities, even if the pragmatic nature of distance education recommends these activities to be concentrated within a limited period of time, so as to reduce this amount of rigidity within an essentially flexible regime.

Distance teaching systems can be planned and installed as dedicated institutions, wherein the main regime of operation is based on the distance learning rationale. The more complete ones display all the functionalities necessary for this regime: developing curricula and designing learning strategies; authoring books and other subject documents; producing and distributing or broadcasting learning materials (from written, audio and video ones, to multimedia); selecting and enrolling students; providing them with appropriate mechanisms of scientific, pedagogic and administrative support: assessing knowledge acquisition and performance of students; providing academic or professional accreditation; monitoring and evaluating the operation, quality and productivity of the whole system.

A pragmatic approach to the same kind of *single-mode institutions* may mean the sacrifice of some of the above functionalities: using learning materials designed and produced elsewhere; giving the power of assessment and accreditation to another institution; in the extreme, just being the provider of learning materials produced by someone else, to the marketplace. Excluding this last case (whereby the organization can no longer be considered as an educational institution), the corresponding savings may have some disadvantages. In most cases, learning materials include cultural references (or culture-determined styles of approach) specific to the origin of their design and contents, which may clash if transferred to another cultural context, thus making it necessary a sometimes very expensive reconfiguration or adaptation. The same reasoning applies to giving the power of assessment to an external entity, which may have criteria of proficiency divergent from the teaching institution.

A different kind of approach to the organization of a distance learning cooperation has been followed, with increasing frequency, by formerly conventional educational institutions which recognize the need to provide learning to extra-mural students prevented, for some personal reason, to attend classes. By introducing a distance learning opportunity just for these students, the institution becomes a *dual-mode system*.

This option have been adopted by a growing number of conventional universities in different parts of the world, as a way to solve the dilemma created by the conflicting tendencies of the increase of demand by large contingents of prospective students and the one of shrinking operation budgets in higher education.

A more comprehensive approach to solve the same difficulties, while probably increasing the quality of teaching, would be to adopt a *mixed-mode* model of operation. Within a given institution, some subjects would be taught in the conventional, classroom way, while other ones, not requiring experimental and laboratory work, nor a significant amount of face-to-face interaction, would be dealt with in a pure distance learning mode, this solution applying to all the students within the organization. Some experiments in this particular field, involving a network of higher education institutions within the same country, are under way.

Even if a mixed-mode model of operation is not formally adopted, institutional cooperation between distance teaching systems and conventional ones, belonging to the same linguistic and cultural area, is always extremely fruitful. This cooperation is a must for single-mode institutions, so that experimental work can be made accessible to their students within conventional universities; these ones can benefit from high-quality learning materials produced by a distance learning system, to be used by their own students; cooperation in scientific and methodological research benefit both parties; interchange of academic staff will be both motivating for the individuals and profitable for all the institutions involved.

The Distance Learning approach has been used successfully in vocational training, either at the initial stage or as continuing, lifelong training. When applied to the workforce of a given enterprise it frequently takes the shape of in service training, learning activities being supported by an Open Learning Resource Centre located within the physical environment of the company. This kind of training facility usually includes a multimedia library, workstations for accessing learning materials and a number of rooms where face to face sessions can take place, led by qualified trainers. Learning activities may be formally organized at fixed times or be left to the initiative of the trainees, according to internal rules; the mixed mode strategy, combining presencial sessions with the self-learning approach, is most frequently used.

Training agencies, both public and private, provide this some kind of services to enterprises which small or medium dimension and their lack of qualified trainers prevent them to install and to sustain a permanent training facility.

Even taking into account the diversity of organizations and institutions providing open and distance learning services and products, both for education and training, in many countries, we are still . far from having a strucutured market in this field. The offer of these services and products is mostly spontaneous, rather then oriented and determined by the demand; from the latter side of the market, experience has shown that. users seldom know how to characterize their exact needs and objectives. Finally, quality of products offered and of services to be rendered is difficult to evaluate for lack of clear and complete specifications; consumer protection is, in most environments, virtually inexistent.

The significant price of ODL education and training services, when provided by private operators, make them too expensive for the current individual end-user. The fact that continuing education has not yet been recognized as an individual and social right prevents the underprivileged categories of users to access its benefits on a permanent basis.

Given the ongoing expansion of ODL systems everywhere in the world, as well as the effect of local and regional alliances currently taking place in order to share the cost of development of new products and to multiply the number of their prospective users, there is some hope that economies of scale cause the corresponding prices to drop in a significant way. This will stimulate the demand, both from enterprises and from individuals, thus furthering the tendency for decreasing the price of these services.

We can understand the structure of costs of a comprehensive ODL system by analyzing the different functionalities it is supposed to assure. Contrary to conventional teaching systems which can be considered as manpower-intensive, distance learning systems are organized as a capital-intensive organizations, requiring powerful technical infrastructures. The logistic and administrative component must be powerful and efficient enough to deal with tens of thousands of students scattered in many different places, possibly very far from the physical centre of the system, and to be able to cope with their needs using a *just in time* approach. Careful planning is obviously the key for success in this operation.

The concept of self-learning is based on the availability of quality learning products, in written and multimedia format; their production is a lengthy process which needs to be finely tuned to the ever increasing pace of technological innovation, of the evolution of standards and of the trends concerning the private possession of communication facilities, to be used by the current students.

In terms of human resources, apart from those operating these infrastructures, the teaching staff splits into two different functionalities, high level specialists of contents, as well as in educational strategies, are needed for authoring the learning products; the tutoring function has to be assured, so that a minimum of student support, educational dialogue and interactivity complements the self-learning process, either in a face-to-face or in a distance communication mode.

Due to the number and specificity of these functionalities as well as to the number of students benefiting from them, ODL systems are complex structures of significant dimension. It is only reasonable that they are designed to serve different purposes and vocations, providing many different streams of education and training, according to the nature of their users. Besides individuals, who enrol in courses and programmes on their own initiative, institutional users, both in the private and in the public sector, are frequently clients of Open and Distance Learning Systems.

Experience gained in international interchange among these systems has shown that public administrations all over the world have been using extensively this kind of facilities for in-service training of civil servants in priority areas like education, health, armed forces and local administration; teacher training and training of trainers are the most common first sectors to be addressed.

In the private sector, we recognise that institutional clients of large dimension use extensively open learning techniques to provide recurrent training to their workforce, covering a large spectrum of qualifications. This makes good sense, for they may have a large number of operating sites across a territory and ODL provides opportunities for significant reduction of the displacement of qualified trainers from one point to another. The argument is even stronger when the company operates at a transnational basis.

Small and Medium Enterprises can not usually afford the creation of their own training centres; they may even lack the know-how needed for a precise specification of their training needs. On the other hand, they are extremely vulnerable to losing competitivity by technological or methodological obsolescence. Besides needing to re-train their operating staff regularly, it is usual they require updating of qualifications of their top and medium level directors and executives in terms of improving organisation, modernising commercial procedures and marketing, introducing information and communication technologies in their whole operation.

The poor structuration of the ODL market of products and services makes it difficult for offer and demand, not only to match, but even to be accurately known by both sides. This means that, besides good and credible providers of these services, others may exist in the field which do not feet minimum requirements of quality; consumer protection mechanisms are also at an incipient stage. This is the reason why governments have given a high degree of priority to stimulating and supporting continues training activities in SME's, frequently through the intervention of national training agencies.

On the other hand, in what respects individual users of distance education and training many countries have created a national ODL system in the public sector, so that either costs to the user are kept at a mostly symbolic level or appropriate financial support is provided by the State, under the shape of scholarships or student loans. In the industrialised countries, given the usually adequate network of formal education institutions, covering the needs of the classes of age from childhood to the young adults, distance education systems are mostly addressed to providing second-chance studies for the adult population, sometimes as part-time students. Adult and Community Education are other streams of operation for these systems, as well as initial and continuing vocational training; central governments or local authorities frequently take the initiative and provide financial support to these learning activities.

The situation is rather different in the most disfavoured regions of the world, on to accounts. First there may be a serious deficit in technological infrastructures, like communication networks, computer systems, even energy distribution; second, the number and distribution of conventional formal education institutions may be clearly insufficient to cover the basic needs in this field. An appropriate answer to these difficulties is to try to boost teacher training to the highest possible level, using distance education techniques and the very conventional media; another one is to develop teleschool systems, defined as conventional classes supported by radio and/or television, more addressed to support the teacher than to teach the learners.

International co-operation is of paramount importance to pool experiences, to reduce costs, to create synergies and economies of scale. While being careful about the transfer of learning materials from the geographical, social and cultural context where they belong, to a very different one (and this requires a significant effort of conversion and adaptation of these materials, in order to perform their cultural re-contextualisation), exchange between national distance education systems is made easier when they belong to linguistic and cultural regions presenting some degree of affinity, regardless of geographical distances.

The recognition of this fact has led to the creation of many different associations linking distance education systems across their national borders. They may have been driven by the use of a common language, by their geographical or political proximity, their social and economic strategies. We have found that ODL transnational associations frequently follow the common interest strategic alliances between countries.

At the global level, the International Council for Distance Education, ICDE, is the federative organisation of most existing ODL systems, represented in 109 countries in all the continents. It is a non-governmental organisation, recognised by the UNESCO as a category A NGO, governed by an Executive Committee including a President, Vice-Presidents representing the various regions of the world and a permanent Secretariat General set in Oslo, Norway. The very recent explosion of ICDE membership, now including educational and training governmental authorities from many countries, as well as powerful international corporations operating in the field of Information and Communication Technologies, has led to the setting up (still on its way of expanding) of a network of regional branches of the Secretariat General, in different continents.

A change in the ICDE Constitution, aimed at increasing and improving the representation of the different regions of the world, not only in geographical but also in linguistic and cultural terms, is now under way. Other new provisions have been introduced to increase the intervention capacity of the ICDE in the international scene, to improve the support given to regional and national associations and to the institutions themselves.

We believe that a clear change in the educational paradigm is nowadays occurring, whereby the autonomy and the initiative of the individual student is being given more recognition and an increased amount of self-learning materials tends to be mixed, in appropriate amounts, with conventional classroom teaching. In organisational terms, this means that a convergence between presence teaching institutions and their distance learning counterparts is also taking place, leading to a subtle change in the role of teachers: instead of being the source of all knowledge, they will become more and more the catalyst of the learning process, working together with their students in the search for a better understanding of fact, phenomenon, environment, society, science and technology, human creativity and human values and references.

The ICDE is giving its own contribution to the analysis of the paradigm shift, through one of the permanent working groups it has constituted for this purpose. With this and many other initiatives under way, in collaboration with national authorities, transnational organisations and international agencies, we intend, as a global even if ambitious aim, to improve, to democratise and to reinforce education and training opportunities all over the world.

The original is presented in English

Commission I

WHAT IS IFIP AND WHAT DOES IFIP DO?

Peter Bollerslev

CHARMAN OF IFIP TC-3 (DENMARK)

I have been asked to give a presentation explaining what IFIP is and how the organisation operates.
I am very thankful that I have been given this opportunity.
I will in my presentation especially focus on the relations to Education.

WHAT IF IFIP?

IFIP, the International Federation for Information Processing is a multinational federation of professional and technical organisations concerned with information processing.

IFIP came into existence in 1960. It was established to meet a need identified at the first International Conference on Information Processing which was held in Paris in 1959, under the sponsorship of UNESCO.

The official relationship with UNESCO is classified as category B, which means, that we are "able to advise in a particular field". In practice this has been carried out through a number of UNESCO contracts, including one on setting up a curriculum in computer science for developing countries.

IFIP has also established official relations with the World Health Organisation, and we have the status of a Scientific Affiliate of the International Council of Scientific Unions, ICSU.

STRUCTURE AND AIMS

From each country, only one organisation can be admitted as a Full Member of IFIP. A typical member is a national computer or information science society. At this moment nearly 60 countries are represented in IFIP.The aims of IFIP are to promote information science and technology by:

- fostering international co-operation in the field of information processing;
- stimulating research, development and the application of information processing in science and human activity;
- furthering the dissemination and exchange of information about the subject;
- encouraging education in information processing.

To fulfill these aims IFIP has set. up a number of so-called Technical Committees (TC's). Each TC is composed of representatives of IFIP Member organisations.

Each TC supervises a number of Working Groups (WG's), which deal with specialised aspects of the field of their parent TC.

Working Groups consist of specialists who are individually appointed by their peers independent of nationality.

TECHNICAL COMMITTEE 3

The Technical Committee number 3 is the Committee on Education.

The active WG's under TC3 are:

- WG 3.1 Informatics Education at the Secondary Education Level
- WG 3.2 Informatics Education at the University Level
- WG 3.3 Research on Educational Applications of Information Technologies
- WG 3.4 IT - Professional and Vocational Education in Information Technology
- WG 3.5 Informatics in Elementary Education
- WG 3.6 Distance Education.

As it is the case with the TC-members, the members of a working group do the work on a voluntary basis. Very often their participation in IFIP activities is subsidised by their work place or by their national computer society.

TYPES OF ACTIVITIES

The working groups arrange different types of activities as for instance:

they may

- give input to TC3 conferences;
- give input to IFIP Congresses;
- produce booklets;
- give consultancy, often in co-operation with UNESCO;
- organise run workshops and working conferences.

At the working conferences they try to fulfill the purpose of an IFIP working conference, which is:

- to discuss in depth a specific subject;
- to convene people working on this subject so that they can benefit from the personal contact and expand their knowledge of the subject;
- to disseminate the collected information and the results of the discussions to the field by means of the proceedings volume;
- to support the activities of the WG.

THE HISTORY OF TC3 AND ITS WG 3.1

Soon after the invention of the computer, it became apparent that computers could not only be used for mathematical calculations, but that they could also be used for various purposes in information processing, that a wide range of people had to learn how to use them and that there was a need to disseminate information about their use. Therefore, to support and coordinate national and international activities in developing curricula and producing education material, IFIP's Technical Committee on Education, TC-3 was established in 1963.

Computer science/Informatics developed rapidly, with its own theoretical foundations, its principles, methods, techniques, and ever broadening spectrum of applications. Moreover, it offered new tools, new ways of working and new kinds of thinking to other disciplines and thus became a basic science with a fundamental character similar to that of mathematics, physics and chemistry. Anticipating this trend, TC-3 started discussing the question of teaching informatics in schools very early in this process.

WG 3.1 Informatics Education at the Secondary Education Level was the first working group and one of its main concerns was teacher education.

WG 3.1 has arranged several working conferences during its 30 years of existence. I can mention some of them to you:

- Informatics and Mathematics
- Microcomputers in Secondary Education
- Informatics and Elementary Education
- The Computer in the Home
- Informatics and the Teaching of Mathematics
- Educational Software
- Informatics and Changes in Learning
- Integrating Information Technology into Education,

and this summer a working conference will be held in Israel on Information Technology: Supporting Change Through Teacher Education. In 1997 WG 3.1 will arrange two working conferences:

- Secondary School Mathematics in the World of Communication Technology: Learning, Teaching and the Curriculum;
- Capacity Building for Information Technologies in Education in Developing Countries.

BOOKLETS

The main concerns of working group 3.1 have always been the impact of informatics on education. This started already in the late 60'es when members of the WG published a series of booklets on the theme of computer education for teachers in secondary schools.

The titles were:

- An Outline Guide to Computing Concepts
- Aims and Objectives in Teacher Training
- The Use of the Computer in Teaching and Learning
- Elements of Information and Information Processing
- Analysis and Algorithms.

These booklets had wide circulation within IFIP Member Organisations, and the WG joined with OECD, the Organisation for Economic Co-operation and Development to help formulate governmental policies.

The booklets are now 15–20 years old and ought to be outdated, but if you read parts of them today you will find to your surprise that their message is still of current interest.

I will leave it to you to decide what that means!

THE HISTORY OF TC3 AND THE OTHER WGS OF TC3

Soon it became clear that the area of information systems was a key component of this discipline. To satisfy the demand for training in this area WG 3.2 was established under the name "Organization of Educational Seminars". An early project undertaken by WG 3.2 was the development of a model curriculum on information system design education. Because of the relevance of informatics to many other disciplines, the scope of WG 3.2 was enlarged and the title changed to "Advanced Curriculum Projects in Information Processing" and later to its current form "Informatics Education at the University Level". Emphasis was placed on developing curricula for Computer Science/Informatics programs. Care was taken to construct a modular curriculum that could serve countries with a wide range of human and computer resources.

The emerging awareness of the impact informatics had on our lives, and the increasing availability of computers, together with new educational theories stimulated the development of many computer-based tools for teaching. There was even speculation (unwarranted!) that teachers could be replaced by computers. During this period TC-3 chartered WG 3.3 "Instructional Use of Computers". During the following years it became clear that several of the activities of this Working Group fit into the specific framework of the other working groups of TC-3. The WG was therefore re-established with the title "Research on Educational Applications of Information Technologies" which better reflected what was needed internationally.

As the number and the size of computer centres grew rapidly, programming and operating computers was no longer restricted to a small number of educated people. It had become necessary to support computer education at the post-secondary and vocational training level. Thus WG 3.4 on "Post-Secondary Education and Vocational Training" was formed to meet this need. The WG title was changed to "IT - Professional and Vocational Education in Information Technology" in 1995.

The advent of microcomputers posed new educational challenges. Computers became part of daily life and even children began using them. In order to avoid misuse because of lack of guidance, and to give all children the opportunity to learn how to play and work with computers in a sensible way, WG 3.5 on "Informatics in Elementary Education" was founded. This working group focused on developing curricula and organizing workshops to assist elementary school teachers to use computers more effectively in the classroom.

Almost everybody had to become computer literate: Mass education was needed. The new communication technologies on the other hand made mass education possible via teleteaching, distance learning, or remote education. The world-wide interest in this new form of teaching has led to the formation of the newest working group, WG 3.6 on "Distance Education".

CONFERENCES AND PUBLICATIONS

In the past, TC3 has tried to be at the forefront in detecting new trends and new demands and to convert insights into appropriate action. One of the main activities of TC3 and its Working Groups has been organizing seminars, conferences and workshops and publishing the results. TC3 has successfully organized its own series of World Conferences on Computers in Education (WCCE)

- Amsterdam, 1970
- Marseille, 1975
- Lausanne,1981
- Norfolk (Virginia), 1985
- Sydney, 1990
- Birmingham, 1995.

The next WCCE will be held in 2001 in Copenhagen.

Let me here try to give you an impression of what is an IFIP World Conference in Education. I will show some video-shots from the previous conferences which was held in Birmingham, UK in 1995. You will see in glimps how such a conference contains large plenary presentations, small discussion groups as well as interaction with pupils, often organised in untraditional ways. *(Video show to be shown).*

I mentioned earlier the many proceedings from working conferences and the booklets and guidelines produced for OECD.

A number of reports have also been produced in cooperation with UNESCO. According to UNESCO two of their all-time "best-sellers" (actually given away for free!) have been, "A Modular Curriculum in Computer Science" (1984, with an updated version in 1994) and "Informatics for Secondary Education - A Curriculum for Schools". The latter curriculum has been translated into French, Spanish, Chinese, Polish, Russian, Japanese and Indonesian.

At present some of the WG's are producing other publications; some are for sale, others are free. Among the latter is a series of "Guidelines for Good Practice" covering up to five titles: "Informatics Education in Secondary Schools", "Integration of Information Technology into Secondary Education", "Telecommunication in Education" and "Integrating Social and Ethical Issues of Informatics into Secondary Education" (in preparation) and finally also in preparation "Guidelines on Informatics in Teacher Education". The working group on secondary education is the initiator of this series.

The working group on elementary education has produced and published a book with the title "Computers in Education: Pedagogical and Psychological Implications". The book consists of essays on the issue, mostly papers written by working group members. Under preparation is another title:
"Improved Information Technology Environments Through Teacher and School Development".

TC3 has also supported the publication of a book on "Success Stories". This publication was the result of a competition among teachers from all over the world. The prize winners were announced at WCCE '95.

FUTURE

What is the future of IFIP TC-3? And where do we go? The establishment of new Working Groups as described earlier shows that the committee is committed to meeting new challenges. We continually follow new developments in the field. A new WG on "Information Technology in Educational Management" is soon to be established.

We will try to strengthen our links with UNESCO in order to help bridge the gap, and we will try to work more closely with computer educators in less-developed countries. Through the auspices of UNESCO we plan to continue disseminating the results of our work to colleagues in developing countries. In addition, we plan to organize, in collaboration with local colleagues, activities and events in developing countries.

We have just launched a new journal "Education and Information Technologies". This journal should be of interest to both experienced professionals as well as those relatively new to information technology. It will be truly international, and it is intended for teachers and trainers, informatics specialists, policy makers, curriculum designers, vendors, vocational trainers and academics at all levels from elementary and primary to secondary to tertiary and vocational education. TC3 members will form the core of the editorial group.

The general trend in most countries is to integrate informatics into existing traditional subjects which are taught in school. The work in TC-3 reflects this trend, and as a consequence we also expect National Informatics Societies to engage more in matters concerning general public education in the future. Along the same lines we will try to attract more members dealing with computer education and the integration of information technology into education into the WG's of TC3.

We are trying to address the "gender issue". There is an imbalance in the membership of the WGs and also in the TC itself. Finally our goal is to make the Committee and its WG's more truly international by actively seeking members from developing countries in all parts of the World.

In TC3 we are also starting to look at Special Education. A high percentage of the populations all over the world has a special learning need. Whether it is a physical or a mental handicap, Information Technology can often enable these learners to participate in ways that were not possible before.

CONCLUSION

Let me finish by mentioning a major concern.

Technology advances rapidly and curricula are normally very slow to change. We should however remember that the use of information technology in education can be the best and the worst thing in the world. It is not so that education will automatically become better because of technology. That's wrong. A bad teacher using technology is still a bad teacher - indeed his or her lack of qualifications may even be amplified. But the proper use of technology can be of tremendous help in education and training - and this in return implies a tremendous effort in the education and training of teachers for elementary as well as secondary and vocational education. I will therefore stress that the issue of education and training of teachers and trainers ought to be very much in focus in the discussions and considerations as well as in our work with bridging the technology gap.

TC3 will continue to play a critical role in producing and disseminating information concerning the best integration of teaching practice with learning strategies by use of technology. Informatics continues to be a rapidly growing discipline which will produce many innovations important to education - either as knowledge to be learned or as tools to be used. An increasing number of people all over the World, children and adults - need education about informatics and its uses. Challenges for IFIP TC3 are greater than ever!

THE IMPACT OF NEW TECHNOLOGIES IN THE SCHOOLS OF EUROPE AND THE G7 NATIONS

Mike Aston

DIRECTOR,
THE ADVISORY UNIT: COMPUTERS IN EDUCATION
(UNITED KINGDOM)

ABSTRACT

The author has been involved with a variety of pan-European research projects seeking to establish the 'state of the art' of educational computing and communications in schools. The findings are rather disturbing. This paper, based on a considerable amount of data collected from over 20 nations, mainly in Europe, seeks to highlight issues concerning the information technology curriculum in schools, national policies towards IT, student access to IT, multimedia, electronic mail and on-line information service provision. The data suggests that many nations are not treating IT in schools as a priority and are very much 'out of step' with IT policy makers in the European Commission. The paper concludes with a suggestion for a much improved partnership in this field between the EU and its constituent nations.

PREAMBLE

In the past few years there have been an increasing number of pan-European programmes that have seemingly focused on Informatics and Learning. The latest of these is the European Commission DG XIII's Telematics Applications Programme which is funding 23 Projects (with 9 on the reserve list) in the Telematics for Education and Training sector. Many of the key actors in the programmes are IT specialists from Universities, non-governmental organisations, research institutes etc. and, no doubt, they all have good intentions towards the various projects with which they are involved. There is real concern that the pan-European approach to improving teaching and learning through the use of informatics, telematics, information technology, computers and communications technology - call it what you will - is supported (or otherwise) by very shaky foundations in the various nations of Europe. The great majority of the member nations of the European Union have tittle in the way of policy towards new technologies in Education and few of them back any kind of strategy with real resources and a realistic teacher training programme. The evidence is that the school Information Technology provision across Europe lacks vision, is certainly under-resourced and is extremely unevenly delivered.

THE REALITIES

Over the last year, a substantial amount of data about IT in schools throughout Europe has been collected, some quantitative and some qualitative [1], [2], [3]. This was in itself a difficult task as a considerable number of Ministries, national and provincial, do not have any meaningful data about IT in their schools. Arguments against collecting data range from *'everything is moving too rapidly* to *'we don't see a need'*. On the one hand we have EU Commissioners and the G7 summit talking about the IT Revolution and on the other, major European nations unable to monitor any changes in teaching and learning that is taking place in their schools.

THE CURRICULUM

If we think of the curriculum as what happens in classrooms in schools ie what is taught and what is learned together with the 'how' - then there are as many variations on the theme as there are members of the EU. In fact more, since a number of nations eg Germany and the United Kingdom, have 14 lander and 4 provinces respectively, each with considerable autonomy on the curriculum. Even with centrally prescribed curricula, local authorities can add regional flavour, schools work with the community and teachers add their own characteristics to classroom practice. Mother tongue apart, a child's curriculum in inner city Athens may be unrecognisable to a child of the same age in a Lapp school in Northern Finland.

INFORMATION TECHNOLOGY IN THE CURRICULUM

Very few nations prescribe any kind of IT in the elementary or primary school phase. Only Belgium, Finland, Denmark, The Netherlands, Sweden and the United Kingdom offer positive IT curriculum support for children below the age of 11. Some parts of Germany are revising curricula to include IT. Britain and Denmark are alone in offering every primary age child an IT curriculum entitlement. If we look at the figures for computers in the elementary schools, we can see from Table 1 that many countries could not offer much in the way of practical IT to primary school children, given the very limited resources available.

The story in the secondary or high school phase is somewhat different, but there are a number of nations, including Austria, parts of Germany, Greece, Italy and Switzerland that have no provision in their curricula for students to gain experience in the use and application of IT. Portugal can only claim to have an average of 4 machines per secondary school - giving, students less than 10 minutes access time per week.

When we search for a commitment to use IT across the curriculum for example in support of the teaching and learning of science or mathematics, we see very little of substance. Denmark and the UK are the only two nations to support initiatives in this area with both written and software resources. It is the case that National Curricula take a long time in the changing. A number of ministries claim to be in the process of revising their Curriculum to include IT but, no doubt, shy away from too much clarity on a student's IT entitlement because of the resource implications.

Table 1

Mean number of micros per school (end of 1994)	Elementary	Secondary
Austria	1.3	15.0
Belgium	5.0	25.0
Denmark	25.0	50.0
England	9.9	85.1
Finland	3.1	10.3
France	1.0	31.0
Germany	2.1	13.0
Greece	0.0	3.6
Italy	3.0	2.9
Northern Ireland	12.0	90.0
Norway	3.2	42.0
Portugal	1.5	4.0
Ireland (Republic)	3.6	12.0
Russia	N/A	*4.8
Scotland	7.0	40.0
Spain	3.2	22.0
Sweden	6.0	55.0
Switzerland	2.0	10.0
The Netherlands	5.3	26.0
Wales	7.0	75.0

* – mean for all schools

NATIONAL POLICIES FOR IT IN SCHOOLS

In any innovative process in education, it is important for the main actors in the process, namely the teachers, the principals, the educational advisers and administrators, to have a clear set of goals over and above the curriculum. It is very rare indeed to find a clear policy on IT in schools. Even in the UK, which has an IT curriculum entitlement for children aged 5 - 16, there is no governmental policy, suggesting for example, that all teachers should aim to have an IT capability demonstrable by the year 2000. The National Association of Advisers for Computers in Education (representative of England, Wales and Northern Ireland) has published a set of Aims for IT in education, namely:

All pupils should develop a capability with IT which enables them to:

make effective use of IT to manage and support the learning process;

choose IT effectively and use IT appropriately to improve learning outcomes;

assess the social effects and implications of IT.

NAACE has also published 10 Objectives for IT in education - one of which is ***"All teachers are capable of using IT resources and applying them effectively".*** The document has yet to become Government policy.

Student's Access to Computers In Schools

There is a very considerable disparity in student's access to IT across Europe, between nations, within nations, between the rich and the poor, between the inner cities and the remote communities and between the genders. Some children have better access to IT in their homes than they do in their schools. Others rely entirely on the school for any access at all. It is impossible to quantify the numbers, but we know many students have no access to IT at all. We are not talking about remote parts of Africa, we are talking about Western Europe.

It is noted, of course, that schools vary in size from 3 pupils in a remote island primary school to over 2000 students in a city high school.

Technological Development

Studies show [2] that many countries in Europe have not kept pace with the technology. Within the G7 nations (Canada, France, Germany, Italy, Japan, United Kingdom and the USA) it is noticed that the nations that pioneered the use of computers in secondary education (and later primary) are more likely to have a greater proportion of obsolete equipment. These are Canada, France, UK and USA. It is very interesting to note that Japan, and to some extent Germany and Italy, have a more up-to-date, and more powerful, installed base.

Moreover we see that there is almost a 'de facto' standard developing in Europe for an educational operating system or environment. Over 85 % of new machines going into schools offer Windows and/or DOS, the remainder being Apple Macintosh or the RISC OS from the British Acorn company. When we look at the installed base, the picture is very different. In France, for example, we find around 40 % of micros in Primary schools being described as pre MS-DOS, with 20 % similarly in Secondary schools. The 1994 Centres de Documentation Pedagogique national catalogue, published in Paris, lists 31 Thomson Nanoréseau packages, 81 MS-DOS, 2 MS-Windows, 1 CD-ROM and 2 Videodisks - demonstrating the lack of investment in software to support the newer technologies. There is not room in this paper to explore the fragmented educational software market in Europe. Suffice it to say that the range and depth of educational software available in any particular country say a lot about how seriously the use of IT is taken by the educational decision makers. It is recognised world-wide that market forces alone will not provide sufficient software to satisfy the needs of the new curricula.

Multimedia in Schools

Data collected at the end of 1995 shows that the penetration of multimedia systems into schools has been slow in a number of countries. The figures in Table 2 show approximate percentages of all schools in a sample of countries, with one or more multimedia systems [3].

Table 2

Country	Primary	Lower Secondary	Upper Secondary
Austria	very few	few	50%
Belgium	100%	*15%	
France	10%	*33%	
Germany	2%	*10%	
Hungary	very few	*few	
Irish Republic	15%	*23%	
Italy	0%	10%	35%
Spain	2%	10%	27%
Switzerland	N/A	-13%	

* - Lower and Upper Secondary combined

We may be witnessing the classical 'chicken and egg' syndrome with multimedia. Schools will not purchase systems until there are more CD-ROMs in the appropriate mother tongue available. Publishers will not invest in software until there are more systems in the schools (and homes?). In the meantime, international publishers like Dorling Kindersley and Microsoft are producing CD-ROMs in the English language and flooding the market places of Europe.

Student's Access to Electronic Mail and on-line Services in Schools

In general, most students, in schools do not have individual access to either electronic mail or other online services such as the World Wide Web. If a school does have a subscription to the Internet, it is very unlikely that all the students will have even limited access without considerable mediation by teachers or school librarians. A very few schools have ISDN connections, thus allowing some simultaneous access, perhaps via a local area network. In practice, the management of schools access to global networks is still on the drawing board and we are witnessing a divisive technology which favours those with access via the home to those with extremely limited or no access at all in the school.

The Professional Development of Teachers and Teacher Confidence with IT

Perhaps the most startling revelation in the G7 research [2] was the lack of support given to teachers' IT development and the low levels of confidence in using IT. The two tables below [2] show comparisons between the European G7 nations and the other three Canada, Japan and the US.

Table3

Teachers' Professional Development (percentages)

	Primary			Secondary		
	Awareness	Short IT Course	Accredited IT Course	Awareness	Short IT Course	Accredited IT Course
Canada	*80	50	30	*80	50	30
France	*80	30	*10	*80	30	20
Germany	*10	*5	0	50	50	*5
Italy	0.	0	0	*25	^5	*10
Japan	24	16	1	43	16	3
UK	91	69	2	83	51	*3
USA	50	50	*5	50	50	*8

* estimate

Table 4

Teacher Confidence (percentages)

	IT Teachers	Subject Teachers	
	Secondary	*Primary*	*Secondary*
Canada	many	50	very few
France	many	few	few
Germany	60	few	50
Italy	few	none	few
Japan	42	8	18
UK	92	56	34
USA	high	low	low

The percentage of secondary school teachers that feel confident about using computers in support of their subject teaching is, in the majority of G7 nations, very low. Only German and British secondary teachers have shown any significant capability in this area. In the Primary sector, it is only in Canada and the UK that a notable proportion of teachers are confident of using IT with their pupils.

Even those teachers with responsibility for teaching computing, are not altogether confident with the subject. The UK is the most successful G7 nation in terms of equipping computing teachers for the job, with Italy and Japan trailing.

Schools without Computers

In the primary sector, 10 % of French, 95 % of German and 57 % of Italian schools are reported to have no computers at all. Of the G7 nations, Italy has around 38 % of its secondary schools yet to install even one computer.

Conclusion. We are witnessing the extraordinary phenomena of significant efforts in concertation from the European Commission in Brussels and a great degree of disorder in the constituent nations. There are some standards emerging in terms of wide area networking, hardware and software environments but none on curriculum, teacher training or policy aims and objectives.

If the European Union is unilaterally to embrace Information Technology in its schools, it needs to consider a number of fundamental issues before investing in too many 'blue skies' initiatives that will disenfranchise even more European citizens of tomorrow. It could be argued that the limited resources of the European Commission should be spent in giving every student a minimum entitlement to IT in school. The constituent nations of the EU would need to be encouraged to commit national resources to attain that entitlement. Only then can Europe begin to involve all of its citizens in the information based society that is rapidly approaching.

Commission II

EDUCATION AND NEW INFORMATION TECHNOLOGIES

Jean A.Vergnes

CONSEIUER DU RECTEUR
RECTORAT DE L'ACADEMIE
d'AIX - MARSEILLE

SCHOOL AND SOCIETY

Nowadays governments of all countries are faced with problems concerning the modernization of education systems, their adaptation to changing conditions and their efficiency. Despite of these systems variety, the problems are formulated almost identically - in the same categories and their solution influences learning programmes, contents and methods of education and all the range of means and methods of data transfer - from classical to the newest ones.

In other words, the world of education and professional training, the world of the *School* broadly speaking (from primary to higher school) should satisfy the requirements of the rapidly changing world community. The member countries of this community, their economy and culture exist according to the rules and are managed with the methods, that have nothing in common with the organization of modern educational systems, which, mainly transfer theoretical knowledge, not the knowledge one needs to live in modern social and economic environment. Moreover, now we know, that the knowledge, obtained after leaving school, cannot be regarded as «final».

The problem appears to be even more complicated, when we start to realize, that it is impossible to ensure that everybody learns even the basic skills in reading, writing, counting, social integration, and, quite recently, typing, the skill necessary in keeping up correspondence, getting access to knowledge and self-education.

In such situation it has become clear from the accumulated experience that the so-called information and communication technologies» could play a decisive role in increasing the School's efficiency and in adaptation of education strategies to the real needs of modern society.

All this is indicative of the fact that the world of education is on the verge of deep transformations -with regard for national peculiarities, the role of the family and associations, interests in industry and national interests, the presence and completeness of basic skills, social differences, globalization of economy and the freedom to move.

All this indicates that the transformation of the School, its tasks and the strategies how to solve them is inevitable. If this did not happen, the School in the forming social situation would be like a railway station, from which no trains depart, while passengers are continuously arriving and thronging the platforms.

All this indicates that we are to build the School which would be more flexible, adaptable to. the requirements of the rapidly developing society and to national peculiarities - a new School for a new society in a new millennium. This will be the «information society», many countries have already joined this society and obtained some advantages. This society will be unlike any other society of the past, and it will be based on the system of social and cultural values, methods and mechanisms of production and distribution, communication between people, between man and machines, between machines, that have no analogues in today's life.

NEW TASKS FACING THE SCHOOL IN THE AGE OF NEW INFORMATION TECHNOLOGIES

New tasks

Is there the need to define the School's tasks anew at the end of this millennium and to start a new big project in the sphere of education? The project can only be realized if new educational and communication technologies available and if leaders of countries and heads of international organizations will be far-sighted.

Why it is necessary to define the tasks of the School anew?

Because too many people do not feel how dangerous the present situation is, when the world of education is at the point of unstable balance, and this instability may be threatening for the foundations of society, because it is deeply rooted: first and foremost is insufficient adaptation of education system to the needs of society. This lack of understanding is often due to the pedagogical illiteracy of those who voice their opinion on educational problems through the mass media.

Recent research, numerous experiments and studies of society's main requirements to the specialists show, that the new School, which we are going to create, from the very beginning of a long-term education cycle (today many pupils cannot complete this cycle at all, or do so poorly) should ensure the acquisition of basic knowledge and skills, not only the knowledge of basic rules of social behavior, speaking, reading, writing, counting, reading comprehension and putting one's thoughts in writing - the skills which were necessary at all times and everywhere - but also skills, which have become necessary only recently, such as understanding of basic environmental problems, basic computer literacy, self-education skills and those needed in search for information, etc.

This basis is to be mastered, taking into account the peculiarities of every given country, to claim that a full course of education is completed.

Compulsory general schooling should teach pupils to learn, thus providing them with one of the most important skills which they will continue to use for the whole life (particularly, in one's career) because the School is unable to teach everything, and the knowledge acquired at school can easily become obsolete.

The survey conducted in 1995 by the Economic Society of Cooperation and Development (ESCD) revealed the illiteracy rate in developed countries, to be more exact the percentage of those unable to understand simple texts. First of all the results of the survey show significant and unexpected difference in these figures in different countries. Absolute values of the illiteracy index vary from 7.5% to 42%. They are shocking, puzzling and causing arguments among many specialists, passions run high, which is natural -high rates of near illiteracy can indicate the failure of education system.

But comparing this index of illiteracy/near illiteracy with the budget allocations for education per capita in investigated countries we can see, that *the amount of allocations cannot explain everything: the illiteracy/near illiteracy rates in two countries can be different, while the budget allocations are the same (or almost the same).* In other words, the efficiency of education system (and, therefore, a safe economic and social integration of the educated individual) does not entirely depend on financing: according to the figures in the ESCD study, the well-known formula «rooms, teachers, money» is not a panacea. Everybody knew about it or guessed it long ago, but it is important, that this guess-work was confirmed by statistics.

Therefore, the efficiency of education systems will depend not only on financing, but also on how we will be able to solve such problems as:

• Structures and methods of management which become outdated: these systems are inflexible, the programmes are behind the times, the projects are economically groundless, there is a considerable difference in the stages at which are pupils in one class, the teachers are confronted with great difficulties in their work etc.

• Negative influence of such factors as «diploma hunting» (the rush for the higher education at any cost), low prestige of manual labour, etc.

• Unwarranted centralized management which results in the projects not fit to be realized on the national scale.

• Insufficient information available to families, moreover - the whole society about the purposes and possibilities of education, while the general public has wrong views on the subject.

• Insufficient use (or no use at all) of information and communication technologies and pedagogical methods, connected with them.

• Insufficient competence of the executives and the authors of projects, their lack of knowledge of local situation'. It results in the fact that numerous commissions, that are to analyze, evaluate, carry out opinion polls, develop and discuss projects in the field of education in general, and in the field of information and communication technologies in particular, do not take into account the multitude of factors including the integration and mutual influence of the cultures worldwide.

UNESCO Congresses

The discussion about the problem of interaction of the School and information and telecommunication technologies[2] has been going on for about twenty years in all countries in which they are introduced and given serious attention.

For more than ten years now these countries have been realizing major projects, such as «Intormatics tor Everyone», which are to attain far-reaching plans and where the problems of education take an important part.

Seven years ago the First International Congress «Education and Informatics» organized by UNESCO took place in Paris in April 1989. UNESCO organized regularly and helped to hold other international congresses under the title «Introduction and Contribution of Information and Telecommunication Technologies in Education»[3].

The interest this United Nations organization gives to the subject shows what hopes mankind pins on the development of information and telecommunication technologies and also the difficulties connected with their introduction in education[4] which become obvious, and the problems connected with realization of the recommendations of all these international congresses and conferences.

It should be mentioned that the rate at which these technologies are introduced in schools has probably become lower, in spite some considerable breakthroughs in the area such as:

• transfer to digital codes and the development of data compression technologies;

• rapid growth of the capacity of information processing means;

• development of computer networks connected to global networks of the Internet type, which is going to be a new social phenomenon when the problem connected with the capacity of communication channels will be solved.

WHY DOES EDUCATION NEED INFORMATION AND TELECOMMUNICATION TECHNOLOGIES?

There are main reasons for that:
• obvious pedagogical effect;
• the fact that education falls technologically behind society;
• economic necessity.

Obvious Pedagogical Effect

There is no need to enumerate technical methods and means, to describe numerous pedagogical experiments, but it should be just mentioned that information and communication technologies ensure new incomparable opportunities of access to information, the cultural exchange, individual approach to education and self-education, including distance education, the choice of necessary programme modules, etc. These technologies being not yesterday that they came into existence, but people are unable to use them correctly, although the fact that there is a great park of these means «standing» everywhere, could make us believe in the opposite.

Taking into consideration great positive experience gained in the field of education, there is no need to prove that information and telecommunication technologies greatly contribute to the development of 'teaching strategies. But the development of these very technologies calls upon us to work out a new strategy of education, in which the teacher will inevitably have to play a new role, because a practical application of these constantly renewable technologies leads mass education to a new model: the most popular will be the most comprising partly individual training and the set of personalized configuration modules[5].

Moreover, it should be emphasized, that the role of the teacher in information and telecommunication technologies is to be regarded in the new light; it is noted by everyone that the fact that these technologies will have to make a great contribution in education is mostly unknown to the general public.

It goes without saying that modern systems of education will not be able to remove easily all the «growth» at the bottom of its ships which hinders its advance: the «ballast» of old projects, reforms, plans, technical means, changing fashions[6] and so on - the whole mountain of hopes which so often were frustrated, will lay obstacles on the way of new means. It is worthless stuff, accumulated because of self-sufficiency and the groundless belief that all these means will be introduced into education of their own accord, that there will be no mistakes, that there will be a general support on the part of schoolchildren, students, parents, teachers, industry and trade[7].

Education is technologically behind society

The following factors are indicative:
• constant growth of personal technical means connected with information and telecommunication technologies in developed countries[8];
• open access to computer terminals in state-owned and public establishments (schools, municipalities, libraries, clubs and associations);
• case with which children master these new technologies;
• opportunity to have access to new multicolor visual information - pictures, new publications;
• development of the global network on the worldwide scale and the opportunity to get know each other better;
• sharp increase in capacity and number of applications of these technologies;
• spreading of these technologies all over the planet, constant reduction in prices and maintenance expenses (as a result of ubiquitous applications of such electronic components as printed schemes, chips, etc.)

Economic Necessity

Even if the means offered by information and telecommunication technologies have not work miracles in the field of education, one cannot possibly imagine how the system of education could ignore them, because these means are increasingly used both at home and at work.

It means that besides various pedagogical considerations it is necessary that schoolchildren and students should master these modern means, which are now regarded as the main working tools and a necessary condition of social and professional integration.

Actually, one speaks about
• means used in new jobs;
• means which change the form and context of work, means of production, consumption, communication, transfer of «know-how», renewal of knowledge;
• means which enable to realize the plans of redistribution of industries over territories, to bring to life remote deserted rural regions, to solve the problems connected with environmental pollution, etc., fully in line with the policy of any government.

The statement of these facts enables to realize the problem: pedagogical opportunities of the given technologies are ignored by the sphere of education (it is more obvious in some countries, less obvious in others), it can be seen in the programmes on all the subjects, in pedagogical strategies, in teacher[9] training[10], in the rates at which the programmes[11] are revised and in the projects financed by the state.

WITHIN THE PRECINCTS OF THE SCHOOL

One should remember that in the 80s the means of information and telecommunication technologies were additional to the teacher's tools. At the time the foundation of the education systems was stable but the efficiency of the given systems did not increase considerably.

Today we are aware of the fact that the pedagogical efficiency of information and telecommunication technologies will be fully obvious only .if the basis of education undergoes drastic changes: education must become partly individualized.

These technologies will inevitably lead to the radical reorganization of such fundamental functions of our sphere as *education, professional training, access to knowledge, know-how, methods of information and skills transfer, preparation for «grown-up» life.*

In these conditions the walls of the School seem to have collapsed. But actually they have become less solid first of all because computer networks, new multimedia carriers and new means to transfer data (such as the Internet, CD-ROM, etc.) have come into existence.

Many more groups of population have come to the School now, and it tries to adapt to different rates of learning, thus ensuring an individual approach. Moreover, because you cannot now have a store knowledge which will be enough for the whole life, people have school and then come back, and this is a life-long process.

The School begins to encompass areas and regions which are located far from traditional educational centres. As a result the developing countries get access to knowledge which was accumulated by the developed countries easily and at low costs, tanks to, for instance, such means as encyclopedias on CD-ROM, self-education programmes on CD-ROM, programmes of progress evaluation on CD-ROM, information data-banks, distance education, cultural exchange through the Internet, etc.

Schools get access to culture and know-how of the whole world regardless of their geographical location. They open their doors and welcome other cultures, new groups of pupils, new specialists, other schools, the whole world.

The School begins to involve the whole society (the professional world, cultural centres, various associations, pupils' families, ministries, etc.) to fulfill its main function — education, 'professional training, and society uses its experience, its experts, etc.

The School becomes more open to the community:
in some classes the latter can better control the teaching/learning process, the way it is organized (getting access to information of the school administration, information about pupils' progress) to learn the results of competitions, correct answers to sums, correct answers to exercises, how to enroll in the given educational establishments, etc.

THE CHANCE THAT YOU SHOULD NOT MISS

The age of new media-technologies does not eliminate most difficult problems which the world of education faces now and which must be solved in any case: whether the new technologies are adopted or rejected. This is, for example, reconstruction and reorganization of school space and school time, the control of this space and time, the reorganization of teachers' training, programmes, content of education, etc.

Nevertheless, the requirements of the training process, social and professional requirements, globalization of Communication, Education arid Economy, political projects of building a new society presupposes the introduction of information and telecommunication technologies into Education.

The School now faces the situation when it must choose these technologies and must solve the problems that go with them, otherwise it may run the risk of finding itself in the opposition to the world of industry, which has mastered the methods of digital coding of information and how to work with them, and also multimedia networks long ago.

In this situation society needs:

- the new Teacher who has mastered all these new means;
- the new School (from primary to higher school), which has turned its face to the new life of society;
- which is new because of its purposes, programmes, content of education, new because it opens its doors for greater number of people, greater number of different categories of people.

But working out such policy, providing necessary material and people resources, working out long-term programmes of realization of these decisions require optimal expenditures, realistic approach, and no sharp changes in the adopted course, if we want it to be a success. We have arrived to such a conclusion because of the experience gained when numerous projects in the field of informatics were carried out in the 80s.

Information and telecommunication technologies give all the nations a new chance which they should not miss: for the developed countries it is a means to reconstruct the «skidding car» of education, for other countries it is the chance to get access to knowledge and know-how of all the nations of the world, to the treasure house of knowledge from all over the world.

To solve the problems of the 21st century it is necessary to define the tasks of the School and the Teacher. To do that it is necessary to understand deeply the interaction between two worlds - the world of education and the world of information and telecommunication technologies and to realize that the world of education should reconstruct its basis thoroughly.

Following this way, the School will be able to regain the hope to increase the efficiency of training, to make education meet the real social and economic demands of society, now and in the future, and to ensure young people the chance of successful social integration.

RECOMMENDATIONS TO THE INTERNATIONAL CONGRESS'

The obstacles on the way to the solution of these problems are numerous, but I am speaking about the greatest challenge in the history, which society should take to be able to survive.

But how these obstacles can be overcome?

The International Congress should formulate appropriate recommendations. There are often very many of them. However, the following five recommendations could be given as the main.

1. It is necessary to give those who make decisions all the information that is necessary for them to understand how important it is to work out a new strategy in education based on information and telecommunication technologies[12], such technologies which cannot go together with old technologies (in this case they will not be effective), but in which have to change old technologies, and in some cases to replace them.
2. It is necessary to ensure good and sufficient training of the teaching stuff for them to be able to use these technologies. This recommendation has been inevitably included in resolutions of all international congresses devoted to these problems for the last ten years.
3. It is necessary to make inventory and the description of all resources accumulated by humanity in the field of pedagogical use of information and telecommunication technologies (the experiments that have been carried out, the programmes that have been worked out, the experience that has been gained, etc.) and to set up the World Data Bank, available through the Internet.
4. It is necessary to work out the main strategies in the development of information and telecommunication technologies and the minimum requirements for their use in education, these requirements should be rather general, so that any country could decide on its own approach and take into consideration its peculiarities.
5. It is necesary to adopt the conception of «partly individualized education based on information and telecommunication technologies» as the one that is to be gradually introduced worldwide[13].

[1] This can explain the low quality of some projects, erroneous evaluation of a situation in submitted reports and the hostile attitude of many teachers to them as far as the problems of introduction of information and communication technologies are concerned a good knowledge of a local situation is necessary as well as the constant renewal of this knowledge if we want to increase the efficiency of projects.

[2] The expression «information and telecommunication technologies» have finally replaced the term «informatics» of the 80s. The word «new» in the term «new technologies» has also disappeared, because what is new for some technologies is not necessarily new for others.

[3] In particular, in December 1990 in Lome (Togo) in the framework of the UNESCO programme «The priority is Africa» the congress was held under the title «Informatics at the serve of Africa». In 1992 under the auspices of UNESCO the international conference «Education without bounds» took place. The resolution of 28th session of the General conference of UNESCO also should be mentioned, it was dedicated to these problems («New Technologies, Communication, Information and Informatics»).

[4] One example of such difficulties is the following fact: the question has been debated for ten years now how to introduce information technologies in schools and further education institutions - as a theoretical or as a practical subject (practical professional training).

[5] What is meant here is partly individual education: 'partly' because traditional classroom education is usually understood as the process of training connected with self-education which is adapted to each pupil and which taken place outside the traditional school (at home, in the 'extended' sessions after classes, in the library, etc.) Under existing conditions information and communication technologies are to play a leading rote. This function has been mentioned in the programmes of all the congresses dealing with education, but it has only found a limited application in the field of education.

[6] The fact that the LOGO language has disappeared without any obvious reason can only be explained by changing fashions. It was a successive teacher's means which came into being because of the development of information and telecommunication technologies in pedagogical sphere, the means which gained recognition throughout the world due to its use in primary schools.

[7] Let us remember that we are speaking now about education as it will be in the next few years, when, according to the experience of the past years, some regular drastic technological changes will take place, which will produce a deeper influence on the world of education than anything that has been invented in the 20th century,

[8] Parents often make certain sacrifices to buy their children personal computers, CD-ROM drives; etc.

[9] Some teachers were quick to master the means of information and telecommunication technologies to use them in teaching. There is various reasons for that: besides purely pedagogical or personal considerations teachers would not like lag behind their own pupils who often turn out to be real computer experts.

[10] The teachers training in the use of information and telecommunication technologies is absolutely insufficient - it is not long enough, it does not in the line with the content of the subjects taught. Very often there is no training at all, more often teachers are given the opportunity to engage in self-education. This statement should not overshadow the fact that teachers themselves try to master these technologies, they should be given the chance to do it and to introduce these technologies into the teaching/learning process.

[11] Everyone remembers that the ball-point pens were not allowed in schools in those days when only pens with metal tips were used. The same happened with calculators. Can we really ignore the fact that the important role the book plays is on the distance, and that the work of teacher, irreplaceable as he is, will undergo changes in due course.

[12] Let us remember that the introduction of information and telecommunication technologies results in a radical reorganization of the two elements in the system of education: teaching function and contents, it will take place by all means, if not now then in the future.

[13] Nowadays this approach is becoming more popular all over the world, every country should give it a serious attention and to find out what has to be done in this respect on the national scale.

The original is presented in French

FLEXIBLE AND DISTANCE LEARNING THROUGH TELEMATIC NETWORKS

Ivan Stanchev

UNIVERSITY OF TWENTE (NETHERLANDS)

1. THE PROJECT

The main mission for the Copernicus Program is: Transfering and developing knowledge to contribute to the rehabilitation of the economy.

In this project we have the following participants:
- University of Twente, The Netherlands;
- University of Exeter, UK;
- Sofia University, Bulgaria;
- Institute of Cybernetics (UNESCO - IIP) Kiev, Ukraine;
- Kaunas University of Technology, Lithuania.

The main project activities are organized around the following two case studies, represented as courses on the Internet:
- Communication and Information Technologies:
- English as a Second Language.

The duration of the project is from 1995 till 1997.

1.1. Project Specifics

1) High communication and information technologies in low-level infrastructure
   - Infrastructure upgrade;
   - Policy making.

2) Transfer of Educational Technology knowledge to Eastern Europe
   - Combined with local subject matter expertize;
   - New approach to education - multiplication opportunities.

3) Open products and architectures

- Extendible with new developments — multimedia, interactivity;
- Updatable content.

4) Mass implementation
- Distance learning centers.

1.2. Project Objectives

• To *establish Internet communication between participants.*

This objective has been met totally. Now the project network is operational and stable, reducing the need of staff mobility and exchange of printed materials. The network includes E-mail discussion groups in six main areas of the project work and an integrated set of WWW sites. Policies and user manuals for use of the Project Network have been developed and distributed between participants.

• *To develop a common project database and the choice of appropriate for the Telematic Research Network (TRN) DataBase Management Software.*

The structure of the database have been developed and approved by all partners. In order to structure also the big amount of Internet and paper references, discovered and used by participants, an electronic catalogue (EC) has been introduced. Now both the database and the catalogue are operational and used by the partners. After evaluation of different alternatives, a combination of WWW and Gopher servers has been chosen as management software (DBMS). The experience from the use of the database leads to the conclusion, that more searching capabilities might be necessary, when the data are growing. Since the database has an open architecture, these capabilities can be added as extensions to the existing WWW server.

• *To develop a pedagogical framework for feleteaching (PF) for teleteaching in individual and group mode and a conceptual model for flexible and distance learning system (FDLS), using telematic networks, creating methods and techniques for courseware development, with respect to different instructional approaches and distance delivery methods.*

The pedagogical framework and the FDLS model have been developed, thus reaching partial objectives for the reporting period. The work is started to be operationalize these theoretical findings into guidelines and instructor manuals. Both CIT and English courses make use of them.

• To *develop and implement CIT and English teaching courses.*

Comprehensive needs analysis have been done for both courses, in cooperation between educationalist and content experts. Special attention have been paid to the needs assessment at the validation sites. The curricula have also been developed, structuring courses into modules to meet different needs. Further, based on the assessed needs, different instructional strategies have been adopted for the courses. The work on CIT course is already at the stage of course micro-planing and technical development. Prototypes of three of the five modules are on the World Wide Web.

• *To develop an appropriate toolbox (software tools and shells) to support course development and distance delivery through telematic networks.*

This objective is planned mainly for the second half of the project, since the toolbox depends on specifications, derived from the actual development work for the courses. The partial objective, achieved during the reporting period, is the analysis and evaluation of the existing software, which could be used for course design, development and implementation. In this scope, comparative study of existing systems for computer conferences and development environments for the Internet has been conducted.

1.3. The cooperation

The coordination and cooperation between project partners is based on the folowing principles:

• Distributed responsibilities, joined effort
Kiev: CIT course, pedagogical framework;
Kaunas: project database;
Sofia: software toolbox;
Exeter: English course;
Twente: research on telematic networks, project management;

• Computer discussion groups on each topic;

• Common standards for exchanging information over Internet - the Net Codex;

• Course prototyping on the World Wide Web;

• Shared electronic catalogue of relevant resources.

2. THE WORKING MODEL

2.1. The work in the project is organized arround 6 Work Packages (WP)

2.2. WP 1 - Communication architecture

The main goals of this WP are to establish Internet communications between the Project participants, installing appropriate hardware and software. Practical results include guide-lines, supporting materials and institutional policies for use of the Internet. These goals have been achieved totally, despite poor communication infrastructure in East Europe and lack of experience in using Internet there. Now the project network is operational and stable, reducing the need of staff mobility and exchange of printed materials. This WP is practically completed.

2.3. WP 2 - Information resources

Creating a Project DataBase and access procedures and creating an Electronic Catalogue (EC) of information resources across the Internet, related to the Project are included in the WP2 as main tasks. A clear structure of the DataBase and the catalogue has been designed and implemented. A lot of useful entities for the electronic catalogue has been selected and annotated at each site, but more coordination effort need to be spend on their integration. The DataBase is operational and used by the participants. The exploitation of the database have shown a need of more enhanced searching capabilities, which can be implemented in the remaining time and effort for this WP, so changes in the Work Plan are not necessary.

2.4. WP 3 - Models and Methods

The main goals of this WP during the reporting period are to develop Pedagogical Framework (PF) for teleteaching in individual and group mode and a conceptual model for Flexible and Distance Learning System, using telematic networks. These two deliverables have been developed at very good quality level, having the potential to be operationalized into guidelines and instructor manuals, which are the future goals in this WP.

2.5. WP 4 - CIT and English Courses

The curricula for both courses have been developed based on thorough needs analysis, in particular for the English course. The content selection and course micro planning have been done in good cooperation between content experts and educationalist from different sites. As a result, a modular structure for both courses have been adopted, in order to meet different needs. The two course are based on different instructional strategies, which, gives opportunities for further research and comparison. Four of the six modules of the CIT course are ready, earlier than the target date.

2.6. WP 5 - Software

An important set of practical results, connected with the theoretical platform of the Project, is reflecting on the development of appropriate software tool - box. Benchmark evaluation of existing software tools and shells, which are supporting the course-development and delivery at a distance has been done, as well as comparative study on the offered computer conferencing software products. Their results have been used successfully for decision making about the tools to be used and as a reference for technological opportunities and limitations in other WP's. The rapid development of such tools in the mean time requires that this evaluation have to continue, with more effort put into developing of benchmarks and specifications for software adaptation. Better communication of the results in this WP among the partners is also necessary. It appeared, that software reviews need to be done prior the main development work on the courses, so they have been started earlier than planned.

2.7. WP 6 - Organisation

An telematic organisational infrastructure have been developed, based on discussion groups, integrated WWW sites and other project management software and policies for their use, thus reducing the need of coordination meetings. All project activities are regularly monitored, so that they are completed in time and in the budget, by shared effort between partners.

3. COURSE BASICS

The courses could be viewed as a case studies for:

- instructional design principles for on-line courses,
- technological framework for course implementation.

These courses are based on the self-study as an instructional design principle, enhanced by following Internet features:

- hyper-text for structured presentation of the material,
- interactivity, allowing experiments,
- communication with the tutor and study follows,
- multimedia (in the future).

The following technological framework is used for these courses:

- World Wide Web (WWW) as delivery platform,
- integration of other Internet services - E-mail, computer conferencing.

3. 1. Curriculum for the CIT Course

CIT course has a modular structure with the following three parts:

- basic part or content environment part (this part includes all main aspects, that are connected with communication and information technologies);
- applied part or implement dependent part (this part includes an educational material "how to use these technologies for implementation of some learner activity");
- examples and assignments for basic and applied parts.

3.1.1. The global objectives of the course are following:

- to learn a different telecommunications media;
- to use telecommunications media as a new form of teaching and learning;
- to work co-operatively to each other in classroom and far away on on-line learning tasks;
- to understand key aspects of technologies that support distance education and new types of educational activities with CMC support.

3.1.2. The expected results of teaching:

- a student "will be has to understand and correctly apply vocabulary and concepts relevant to present-day discussions of distance education and on-line learning";
- a teacher "will be able to use the Internet as a designer of educational resources".

3.1.3. Introductory, Technological and three Applied Modules of the CIT Course

This on-line course will help to learn how to use the Internet: electronic mail, computer conferencing, World Wide Web, on-line databases and global networking for distance learning. This is a four-months on-line course. The course has modular structure:

- Introductory module - about communications between people, computers, etc;
- Technological module introduces existing features in CIT;
- Applied modules deal with using CIT in different areas: education, engineering, business.

The course aims are:

- To give students an opportunity to discuss and test the strengths of the Internet as teaching and learning medium;
- To provide students with new forms of teaching and learning using ideas and techniques of distance learning;
- To familiarise students with telecommunication applications in education, engineering and business.

The course will help:

- To gain first-hand experience of potential uses and limitations of electronic mail;
- computer conferencing, FTP services, TELNET logins, newsgroups, World Wide Web, the Internet informational resources (Gopher, Veronica, WAIS);
- To use the Internet as a teaching and learning medium; design an on-line course;
- environment to suit your own open and distance learning situations and objectives and discuss them on-line with other participants and teachers;
- To develop authoring skills with WWW publishing;
- To work co-operatively from a distance solving different learning tasks.

3.2. Curriculum and Outline for the English Course

The main aims of the course are to:

- build on Copernicus links to establish functioning distance learning networks between participant institutions;
- introduce and develop pedagogical and technical concepts relevant to distance and flexible learning, with particular reference to English Language Teaching;
- help participants to experience the potential and problems of distance education;
- develop IT and course design skills of participants to a level where they can plan and carry out their own courses;

- support participants in the production of a course appropriate to their own teaching environment;

By the end of the course participants should;

- know more about IT and its applications to distance learning in an ELT context;
- be familiar with the basic issues in flexible and distance learning;
- understand some of the practical questions related to distance course design and implementation;
- be able to use up-to-date Telematics methodologies to communicate, particularly e-mail and World Wide Web;
- be able to contribute to the MAPS course Web page;
- have planned a course specific to local student needs.

The overall course outline is only a framework. Much of the detail is flexible and there are a number of areas where negotiation will be required between participants. Participants will also be able to call on other members of Copernicus teams for support, for example in a technical context. Some of the main course elements are described below.

4. MAIN RESULTS AND ACHIEVMENTS SO FAR

4.1. Expectations for Implementation and/or Exploitation

The two courses to be developed (CIT and English) are expected to be included, after the validation phase, in the regular distance education programs at the participating institutions.

The preliminary teacher training course (see Major Achievements, p.5) is already included in the regular Continuing Professional Development programme at Exeter University, School of Education.

The M.Sc. Program "Educational and Training System Design" at University of Twente, Faculty of Educational Science and Technology currently uses the results and expertise from the project for developing Internet based courses. It may use them too for moving all existing core courses to the Internet platform for distance delivery.

The main scientific results wilt be disseminated both through the traditional channels of publication and conferences and by using the Internet in its current and future forms, for the benefit of research community.

The technological, communication and informational infrastructure, especially the electronic catalogue and the database, will be used to create a community of practice which will continue to grow after the project is itself completed.

New information technologies applied within all phases of education have a significant effect on basic literacy of a population, permitting a widespread application of Communication and Information Technology (CIT) in commerce and industry. Making use of English language is a very important advantage for all users of new information technologies.

CIT application to flexible and distance learning directly and through pre- and in-service teachers training will cause to rapid integration CEE countries and NIS into European Community. A prerequisite for this application is a good command of English language, which also can be built.

4.2. Major achievements till now:

- Internet connections and working practices between 2 EC (The Netherlands and UK) and 3 CEE and NIS (Ukraine, Bulgaria, and Lituania) countries have been established for collaborative research and teaching.
- A model for lifelong, Flexible and Distance Learning System (FDLS) in communication and information technologies has been developed, which is appropriate for the CEE and NIS countries, and valuable for EC countries. A pedagogical framework for teachers has been developed as practical application of the model.
- A modular World Wide Web based course in communication and information technologies has been designed and partly developed to support professionals in different areas (teachers, engineers, businessman) in Bulgaria, Lithuania, and Ukraine.
- A method for user involvement (English) teachers) in design and development of a World Wide Web based course in English as second language has been developed and applied. The course itself has been designed in cooperation with the selected user group. This method includes a preliminary course, given to the teachers to help them to collaborate in the design and development process.

4.3. Expected end-products:

- Pedagogical Framework for development and implementation of open and distance courses.
- Internet based training course in Communication and Information Technologies (CIT).
- Internet based teacher training course in FDLS for English Language Teaching.
- Software toolset for development of training courses on the Internet.

4.4. Problems encountered

The poor telecommunication infrastructure in participating countries from Eastern Europe makes difficult the cooperative course development on the Web, especially during the phase of making interactive WWW pages. Even the expensive leased lines are not of sufficient quality.

The purchase of necessary equipment for the East European partners have been obstructed by the custom formalities. Although there is an agreement between EU and participating countries from Eastern Europe for duty- and tax-free import of the equipment, there are long and unclear procedures to make use of this agreement. These formalities delayed the establishment of the Project Network more than one month and were repeated during the next equipment purchases.

5. COURSES DELIVERY AND EVALUATION

One of the main goals of this project is the following distance courses to be delivered: Communication and Information Technology (CIT) course and English Course. At the end of the year all the courses should be on the WWW. This two courses will be developed for three target groups: pre-service teachers, students in engineering and students from a MBA program. So we will have 6 user's groups: pre-service teachers (CIT course), pre-service teachers (English course), students in engineering (CIT course), students in engineering (English course), MBA students (CIT course), MBA students (English course). First two groups will be located in Kiev, next two groups will be located in

Klaipeda (Lituania), and last two groups in Sofia.

The groups in Kleipeda will include nine students each from University of Kteipeda (KU), with visiting lecturer (one time per month for two days) from Kaunas. Students of KU are seeking for master degree, in Computer Science specialisation, fifth year students. Students are full time employees in companies, offices and SME. All of them are interested to use flexible and distance education possibilities as an alternative for face-to-face seminars and lectures. Student in Klaipeda have classes on PCS with Windows and email boxes. They don't have other access in classes, but could have access in free time.

The groups in Kiev will be actually four (two for English Course and two for CIT course), with about fifteen students each, from two different Universities in Kiev. Each group will have technical assistant and responsible lecturer. Students will work 2 times each week for two hours for the whole period - four months. Students are pre-service teachers in their fourth and fifth year and are interested to use flexible and distance education in their future practice. They have classes on PCS with Windows.

The groups in Sofia will include: one about twenty students from University of Sofia having 60 hours (15 weeks X 4 hours each), and other about 16 students having no regular classes but working in their free time, possibly from a distance. Each group will have technical assistant and responsible lecturer. Students are seeking for master degree in MBA in their fourth or fifth year. More of the students are part time employees in companies, offices and SME, which have their own Internet connections. Students have classes on PCs with Windows95, MACs and SUN Workstations. They have full Internet access in classes, but could work also in their free time.

One of the main contributions of users groups should be in the development of conceptual model for flexible and distance learning system (FDLS), using telematic networks and for creating methods and techniques for courseware development, with respect of different instructional approaches and distance delivery methods. Practical results are connected with elaborating guidelines and instructor manuals for courseware development and implementation of the framework in training and courseware development intensive courses with teachers and instructors.

Another contribution will be in the adaptation and the development of the supporting materials as well as in the course delivery (pilot experiments), course evaluation and other necessary follow-up activities for the course refinement and improvement.

The overall contribution of all these groups to the project will be twofold:

- they will help to test, evaluate and improve the courses developed;
- they will contribute to the course content and delivery, having to complete course works directly linked to the overall course objectives.

The two courses to be developed (CIT and English) are expected to be included, after the validation phase, in the regular distance education programs at the participating institutions.

In order to enhance the courses with multimedia capabilities and to strength the implementation opportunities by involving new partners and create new courses, a proposal for a follow-up project has been made under INCO-Copernicus Program - "Multimedia applications for educational telematic networks". The proposal was selected by the EC for financial contribution.

The preliminary teacher training course, delivered to the user representation group, is already included in the regular. Continuing Professional Development programme at Exeter University, School of Education.

The M.Sc. Program "Educational and Training System Design" at University of Twente, Faculty of Educational Science and Technology currently uses the Pedagogical Framework and expertise of the project participants for developing Internet based courses. The program plans to continue this cooperation in moving all existing core courses to the Internet platform for distance delivery. In this case a Bulgarian small enterprise - VIRTECH Ltd. - will be commissioned to do the technical development, making use of the software toolset, developed under the project.

The technological, communication and informational infrastructure, especially around the electronic catalogue and the database, will be used to create a community of practice which will continue to grow after the project is itself completed. This has not been foreseen as a commercial service in the mean time, but as a open forum for instructional designers and course developers across Western and Eastern Europe.

6. END PRODUCTS OF THE PROJECT

6.1. Pedagogical Framework for development and implementation of open and distance courses

The pedagogical framework is based on a theoretical model of Flexible and Distance Learning Systems, developed under the project. Its purpose is to help the teachers and content experts in design, development, and evaluation of distance education and training courses, especially delivered via telematic networks.

The framework consists of a Teachers Guide and a Student Package.

The guide mainly deals with distance education from a methodological point of view. Although many aspects of distance education are quite similar to traditional education, the guide stresses on the specifics of distance education and particularly on the use of new information technologies as instructional media. The guide also describes activities which have to be performed during the development and implementation phase.

The student package describes the tool students need to follow the courses, developed under the framework, the ways these tools will be used and the preliminary knowledge and skills students need to use them.

6.2. Internet based training course on Communication and Information Technologies (CIT)

The course has modular structure.

Introductory module is about communications in general - between people, computers, etc.

Technological module introduces existing features of the Internet literacy and beyond.

Applied modules deal with using CIT in different areas: education, engineering, business.

Each CHAPTER will highlight a different aspect of CIT.

When a student has learned all the chapters of the course, he will gain experience of teacher-mediated discussions, one-to-one and one-to-many communications by e-mail, and group collaborations, and independent work with the Internet resources (FTP, TELNET, GOPHER, WWW, etc.)

By the end of the course a student will be able to apply some useful concepts and techniques you will gain from the course to your own contexts.

Course aims:

- To familiarise students with telecommunication applications in education, engineering and business.
- To give students an opportunity to discuss and test the strengths of the Internet as a teaching and learning medium.
- To provide students with new forms of teaching and learning using ideas and techniques of distance learning.
- To gain first-hand experience of potential uses and limitations of electronic mail, computer conferencing, anonymous FTP services, remote TELNET logins, newsgroups, World Wide Web, the Internet informational resources (Gopher, Veronica, WAIS).
- To use the Internet as a teaching and learning medium; design an on-line course environment to suit your own open and distance learning situations and objectives, and discuss them on-line with other participants and academic staff teachers.
- To develop your skills as an author of your own WWW pages. On completion of the course you will be given a certificate describing the course coverage and recording your participation.
- To work co-operatively with each other in a distance solving different learning tasks.

Benefits:

- Gaining first-hand experience of potential uses and limitations of electronic mail, computer conferencing, anonymous FTP services, remote TELNET logins, newsgroups, World Wide Web, the Internet informational resources (Gopher, Veronica, WAIS).
- Using the Internet as a teaching and learning medium; design an on-line course environment to suit your own open and distance learning situations and objectives, and discuss them on-line with other participants and academic staff teachers.
- Developing authoring skills for WWW publishing. On completion of the course students will be given a certificate describing the course coverage and their performance,
- Co-operative work with other students, possibly from different countries, solving different learning problems at a distance.

6.3. Internet based teacher training course in FDLS for English Language Teaching

6.3.1. Course aims:

- introduce and develop pedagogical and technical concepts relevant to distance and flexible learning, with particular reference to English Language Teaching;
- help participants to experience the potential and problems of distance education;
- develop IT and course design skills of participants to a level where they can plan and carry out their own courses;
- support participants in the production of a course appropriate to their own teaching environment.

6.3.2. *Structure*

Module One:...........Introduction to telematic Communication.

This deals with IT concepts and methods of distance communication.

Module Two:...........FDLS pedagogic.

This looks at the parameters and issues related to FDLS and compares them with traditional learning methodologies.

Module Three:........Examples of teaching and learning materials.

This will provide examples of distant ELT materials and will compare them with classroom-based approaches.

Module Four:.......... Course Design.

This will look at the various stages of designing a distance ELT course.

Module Five:.......... Local case study preparation.

This is a specific location-based module designed to support participants in the preparation and delivery of teaching materials appropriate to their own situation.

6.3.3. Benefits

By the end of the course participants will

- know more about IT applications to distance learning in the context of English Language teaching;
- be familiar with the basic issues in flexible and distance learning;
- understand some of the practical questions related to distance language course design and implementation;
- be able to use up-to-date telematics methodologies to communicate, particularly e-mail and World Wide Web;
- be able to design educational Web pages, in particular pages for language teaching and support;
- be able to plan a course specific to local student needs.

Since the participating academic staff teachers will be able to design and develop distance courses in English language teaching, a cascading effect is expected in developing custom-made courses of this kind in participating institutions, countries and regions.

6.4. Software toolbox, containing software tools and shells to support course development and distance delivery through telematic networks

The purpose of the toolbox is to facilitate and speedup the development of training courses on the Internet and to support the implementation and delivery of these courses.

To fulfil these requirements, the toolbox will include:

- High level integrated authoring tools for WWW pages. Both static information presentation pages and interactive exercise pages will be supported. No technical knowledge on HTML or programming skills will be necessary.
- Tools for automatic publishing of the produced materials, version and project management.
- WWW server extensions and gateways to other software (e.g. databases) to support monitoring of the student activities, provide personal feedback to students and student administration.
- WWW based tools for communication, discussions and cooperative work.
- Design templates for different instructional strategies and course models, based on the Pedagogical framework and teacher guides, developed under the Project.

6.4.1. Benefits

For content experts, academic staff teachers and instructional designers – opportunity to produce effective technology enhanced training and educational materials without a need of technical development staff. This could result in shorter development time, better control over the whole process and cost reduction.

For publishers and software developers - reduced development time and partial overcoming the lack of knowledge on instructional design, as well as improved consistency and user interface of the end product.

7. CONCLUSION

7.1. Contribution to the application domain

The proposed research is expected to build a technology-based bridge between CIT Teacher Training in the CEE & NIS and EC countries. It will offer a model for FDL that allows learners to acquire skills and knowledge at their own pace, to choose the location of study (at home, at a workshop, at school, etc.), to choose the time for the group sessions, to navigate in a modular curriculum by using flexible learning materials based on CIT. We expect a significant contribution to the development of CIT Teacher Education in all participating countries and corresponding impact on the society.

Properly designed educational software, learning materials and activities will allow teachers and students to process and analyse scientific data, to have discussions with distant partners, to collaborate for producing technology-based learning materials.

The modular teacher training course on CIT that utilises the FDL model will allow to overcome a paradox situation in the education when CIT became really open to general use but they couldn't be. effectively applied because teachers can't manage to include them to their didactic repertoire. The creation of a telematics network for teacher educators provides an important infrastructure which will improve the quality of teaching and research across Europe as well as supporting flexible and distance learning. TEFL will also be considered as a first case to inform the development of similar networks for other disciplines and will be the first telematics network of its kind in the world. It is expected that the courseware, protocols and pedagogy will be transferable as will the technical developments and some of the equipment.

The language engineering aspect will provide new forms of computer-aided language learning (CALL), which will not only enhance the teaching and learning but permit teachers to adjust materials to, the wide range of students, including the pressing needs of university staff. This will be a step towards development of language engineering standards.

The case of English as a foreign language has been carefully chosen also to enhance the use of telematic networks and CALL internationally including the CEE and EC. Teachers of English will also support their colleagues within their own countries and they frequently support clients in commerce and government too, as least in the early days of an innovation. In addition universities prepare teachers in the schools and thus the next generation. This project therefore has important multiplier effects throughout the community within and across countries and will influence the development and uptake of systems for business, home and personal use.

7.2. Dissemination activity and plans

The main scientific results will be disseminated both through the traditional channels of publication and conferences and by using the Internet in its current and future forms, for the benefit of research community.

The two courses to be developed (CIT and English) are expected to be included, after the validation phase, in the regular distance education programs at the participating institutions.

The preliminary teacher training course (see Major Achievements, p.5) is already included in the regular Continuing Professional Development programme at Exeter University, School of Education.

The M.Sc. Program "Educational and Training System Design" at University of Twente, Faculty of Educational Science and Technology currently uses the results and expertise from the project for developing Internet based courses. The Program aims to continue this cooperation in moving all existing core courses to the Internet platform for distance delivery. In this case, the actual development work will be done by a small Bulgarian enterprise - VIRTECH Ltd.- making use of the guides, manuals and software toolbox, made under the Project. A preliminary agreement between the Project Coordinator, the M.Sc. Program management and VIRTECH have been reached.

The technological, communication and informational infrastructure, especially the electronic catalogue and the database, will be used to create a community of practice which will continue to grow after the project is itself completed. Members of academic staff at University of Twente and GMD (Germany) already make use of the electronic catalogue.

The educational services, offered at a distance by participating institutions have been enhanced by adding flexibility, openness, interactivity and more communication capabilities, which are included in the courses, developed under the Project.

The internet course development services, offered by Internet publishers or software enterprises can be enhanced by use of the software toolbox, guidelines and manuals, developed under the Project, in terms of reduced development time, proven educational value of the courses and professional user interface.

The combined application of the Pedagogical Framework, teacher and developer guidelines and the software toolbox could develop a new service - direct development of Internet based distance courses by content experts and instructional designers, without need to involve software designers and programmers.

The leading design principles and technology in Web development have been catched-up and applied to the field of instructional design

The expertise and know-how in open and distance learning from leading Western Universities have been transferred to the participating institutions from Eastern Europe, thus putting them in the leading position in Eastern Europe and creating opportunities for further spreading of expertise in this region.

7.3. The main conclusions from the project so far are:

- The adaptation of educational pre-normalisation & standards (including software and hardware) for CEE and NIS countries will facilitate the development of portable- technology-based learning materials appropriate for different educational settings and cultures.
- Properly designed educational telamatic applications, learning materials and activities allows teachers and students to process and analyse scientific data, to have discussions with distant partners, to collaborate for producing technology-based learning materials.
- The modular teacher training course on CIT that utilises

the FDL model helps to overcome a paradox situation in the education when CIT became really open for general use but they could not be effectively applied because teachers cannot manage to include them to their didactic repertoire.

- The language engineering approach to the English course provides new forms of computer-aided language learning, which will not only enhance the teaching and learning but permit teachers to adjust materials to the wide range of students, including the pressing needs of university staff.

7.4. The main future possibilities foreseen now are:

- To analyse and utilise from educational perspective the new technological developments in telematics, in particular multimedia and enhanced interactivity, and to incorporate them into the developing courses.
- To derive clear specifications for the software toolbox, based on the conducted reviews and on the experience earned during the course development, and to develop the toolbox.

DISTANCE EDUCATION IN NEW INFORMATION ENVIRONMENT

V.S. Meskov

DEPUTY CHAIRMAN OF THE STATE COMMITTEE
FOR HIGHER EDUCATION OF THE RUSSIAN FEDERATION

Apprehension of the fact that the future of the mankind, its survival, is connected with the future progress of science and education, had led to the considerable enlargement on the share of learning young people of corresponding age groups. By the beginning of 1990s the number of learners in the world had increased threefold in comparison with 1960, and amounted more than 900 million. The entrenched traditional systems of higher education became unable to accept the increased flow of students. Besides that, they turned out to be unable to waive theirs principles of classical university education, and to re-orient the process of learning on the training of specialists in economy, while the demand for them was enlarging constantly, being afraid that excessive professionalization of education might water the universities down and convert them into highly specialized educational institutions.

The way out from that controversial situation was founded in partial professionalization or university education, creation of a network of new type educational institutions in the system of higher education, targeted training of specialists in the sphere of economy, considerable expansion of extra-mural tuition on the basis of new information technologies, and, in addition, general recognition and new impulse for development was received by distance education (DE).

The numerical growth of students was accompanied by the creation of absolutely new (non-traditional) types of institutions of higher education. Since the beginning of the century the number of it increased more than 700 times.

The stable growth of the share of extra-mural students who work and study at the same time is followed by rapid development and broad application of various technical means, that provide higher quality of this education. Among them there are the following technologies:

- computer and information technology;
- satellite systems of communication;
- educational television (including cable television), videotapes;
- mass telephonization, enabling to link up to information systems;
- global and regional networks, Internet, etc.

A number of students prefer DE deliberately, because of the purely financial considerations - the extra-mural education allows students to keep their employment and thus to support themselves.

A demographic factor plays its significant role in the progress of DE.

There is another positive factor for the benefit of further DE development. Through it the number of educated people increase more rapidly than that through other forms. An insignificant number of tutors can teach a great number of learners, including those who were unable to gain higher education at a "normal" student age, and those, who cannot attend traditional educational institutions' because has physical lacks.

The higher educational establishment has faced difficult tasks, connected with the extension of lifelong education programs, in-service training and re-training of specialists.

The philosophy of UNESCO and other international organizations acting in sphere of education, is that reform and innovations in higher education should be aimed at conversion of various theories and conceptions of lifelong education in reality, and rigid, inflexible, and elite systems of higher education should be made accessible to all.

Distance education is called to give an adequate answer to the educational challenges of the future society.

According to the Concept of RF Ministry of Education, the introduction of distance education in the system of personnel training will broaden the number of consumers of educational services, including the inaccessible and sparsely populated areas, in remote regions. Distance education, is considered as one of the forms of the lifelong education system, which is intended for realization of the human right to obtain information.

According to the Concept, *distance education is understood as a complex of educational services. offered to broad strata of population both in the country and abroad with specialized information-educational environment on any distance from an educational institution.*

The information-educational environment of distance education is a system of communication means, information resources, protocols of interaction, hardware and software, methodological provision, aimed at the satisfaction of consumers' educational needs.

The traditional educational system is based on lectures, seminars, laboratory studies, games, independent learning. The book is the educational basis, and the teacher is the interpreter of knowledge.

The distance education Concept is targeted at the introduction of other educational models in the process. These models foresee the teleconferences, information performances (i.e., students' work with databases, student projects, ratings, etc.). The application of new organizational forms of education changes radically the method of learning, together with the interrelation between the student and the teacher. In these models, databases and books are the information source, the teacher is the co-ordinator of the learning process, and the student is the interpreter of knowledge. So, the teacher's role in the educational process is changed. So his/her functions are to co-ordinate the learning process, to correct the course, to advise in connection with the development of individual curriculum, to guide the student's projects, etc. He guides student groups of mutual help, helps students in their professional self-determination. The student's activity changes from the reception of knowledge to independent search for the latter, to creation of independent educational curriculum.

The technology of distance education is an aggregate of methods, forms, and means of cooperation with a student in the process of independent, but guided learning. As the information and education environment is being filled with the necessary content, and provision of universal distant access to the environment is secured, an open information-educational environment will be created. Information to learners may be presented in the form of printed materials (sets of textbooks and methodological literature, and tasks), electronic materials (computerized educational environment, databases, electronic textbooks), audio- and video-materials, and television broadcasts.

The ultimate goal of creation and development of the distance education system is to grant school-students, students, civilian and military specialists, the unemployed, general public in any area of the country and abroad, equal educational opportunities, and to raise quality of education through more active use of scientific and educational potential of leading universities, academies, institutes, leading training and re-training centers under the branches of industry, institutions for re-training, and other educational institutions.

As it was mentioned in the Concept, at present the development of an unified system of DE in Russia is a pressing issue, since it will be able to the most adequate and flexible react to the needs of the society, and provide for realization of the constitutional right to get education by each citizen of the country. The system of distance education corresponds with the logic of development of the educational system and the society as a whole, where the needs of an individual are of paramount importance. Besides the system of distance education may play a role not only of an instrument which satisfies, but also forms educational needs of a human beings, according to the interests of the each human being and of the society.

Connecting the problem of bridging distance between a teacher and a student with technical capabilities of modern electronics, scholars come to the conclusion that the solution of an issue on methods (ways) of bringing distance causes a fundamental change in opinion on the essence of the learning process itself. This is substantial for the countries which do not have national DE systems yet. The introduction of modern technologies makes it possible to surmount substantially conservatism and rigidity of the frameworks of traditional educational systems and "totalitarianism" of tutors, and to create an open educational environment, where a student is not an object, but a subject of education.

The prospects of further DE expansion are connected with the new achievements in the means of communication. An important role is given to the development of communication satellites, which enable to create inexpensive special purpose translation networks for learning.

Information technologies of distance education may be divided into three big categories: *non-interactive* (printed and audio-visual materials), *computer-based instruction* (including the most up-to-dated multimedia), and developed means of telecommunication *videoconferences*.

The means of computer-based instructions and telecommunications provide distance education with radically new opportunities, and they are progressing rapidly in the form of electronic textbooks and hypertext transmission technology via e-mail.

Developed means of telecommunication, satellite communication and transmission of video image via computer networks, have recently entered the practice of distance education only, primarily because of absence of developed communication infrastructure at early stages of DE formation, and high cost of lease of communication channels and transmission and receiving equipment and information.

Looking forward, one can see already now, in what way new technologies come forward to the scene of distance education. Almost all of them are based on digital methods of information processing. They are used both in hipermedia programs, which allow the student to operate the used information, and large-scale data and knowledge bases, accessible via global computer networks, and integrated data systems, allowing the student to have access to video-programs, audio-materials, databases, software, both from home and office.

It is recognized that a information society needs to establish an open educational environment, that is why it is advisible to fulfil under the UNESCO umbrella the following tasks:

- to form a global bank of distance learning sets, distance educational programs;
- to develop multichoice programs and sets for distance learning which take into account national peculiarities of consumers, countries that have insufficient educational services;
- to develop a unified multi-language educational system of educational terms, including the DE terminology;
- to set up conditions for free use by countries of the global community.

LOOKING SIDEWAYS

John Middleton

CHIEF, THE WORLD BANK
INTERNATIONAL BANK FOR RECONSTRUCTION
AND DEVELOPMENT
NEW PRODUCTS AND OUTREACH DIVISION

In addressing issues of international co-operation, the Commission may wish to consider three key issues. First the technologies will be only as useful as the knowledge they carry. Where will this knowledge come from? Who will it be for? Second, while knowledge alone is a important to the human spirit, knowledge in use is the key to positive social and economic change. What can be done to enable individuals and institutions to use knowledge more effectively? Third, we know that global corporations are at the cutting edge of the use of new technologies for learning. How can this experience be shared? These issues are explored for their implications for international co-operation.

The commission will address issues of international co-operation in the promotion of the new information technologies (NIT) for education. The Main Working Document ably identifies the many issues associated with the technologies and their implications for learners and teachers, social, economic and cultural development, and educational policies. The issues identified for international co-operation are mainly focused on UNESCO and on the technologies, and properly so.

However, I would suggest additional issues that the Commission may wish to consider in addressing the role of UNESCO and the broader international community. First the technologies will be only as useful as the knowledge they carry. Where will this knowledge come from? Who will it be for? Second, white knowledge alone is a important to the human spirit, knowledge in use is the key to positive social and economic change. What can be done to enable individuals and institutions to use knowledge more effectively? Third, we know that global corporations are at the cutting edge of the use of new technologies for learning. How can this experience be shared? I will briefly explore these issues, and conclude with a few tentative thoughts about their implications for international co-operation.

ISSUES

Knowledge From, Where and for Whom?

It is not just information technology that is changing. Many nations are undergoing both economic and political transitions. These transitions bring with them enormous demands for knowledge, not just from students, but also from the public at large; not just from public officials, but also from the private sector. Much of this demand is for knowledge that is built on the experience of other nations and other citizens. The new technologies offer the potential, realized in some nations but far from all, to provide access to this knowledge. But who will provide it? How can we increase the chances for knowledge to flow, not from the rich to the poor, but among nations and citizens as information equals?

Putting Knowledge to Work

At the center of our concerns for equitable access to technologies and the knowledge that they can carry should be the continuing global effort to reduce poverty through sustainable and equitable development. Economic growth is a necessary, although not sufficient, means to this crucially important end. Four decades of economic research has provided us with important lessons about how growth can be achieved. Policies that open economies to international trade, a reduced role for governments in those parts of the economy best managed by a competitive private sector, a stable legal and regulatory environment, and investment in both physical and human capital are widely accepted as essential to growth. Governments play a key role in ensuring equity and in providing those public goods, such as education, that enable citizens to share in the benefits of growth.

Recent research suggests an additional important factor. That is the efficiency and effectiveness with which nations use resources, both physical and human. A recent study by Mancur Olson provides a powerful example for human capital. The incomes of migrants from poor to rich nations rises much more than can be explained by access to the greater resources of the receiving nation. Olson concludes that the difference represents "...human capital, entrepreneurial spirit, and cultural traits..." that were under-used in the country of origin.[1]

We are all aware of the many and complex factors that could lead to less than effective use of knowledge. Indeed, capacity building has been a central concern of global development effort. But we must also recognize that this effort has been only partially successful. Thus both economic analysis and the record of experience suggest that the new technologies will be effective in putting knowledge to work only if they are accompanied by a fresh approach to capacity issues. Good policies and investments will help, but institutional factors will matter as well. What role should the international community play in building the capacity of citizens and nations to use their knowledge to improve individual and social welfare?

Experience of the Private Sector

I recently attended a presentation by a team of course developers working for two global automobile manufacturers who are developing management skills training programs for subsidiary organizations in a dozen countries. Team members were based in the US, Switzerland and Spain. They work together effectively via computer and telephone links despite technical obstacles. Several elements of their experience are worth considering. First, two companies are collaborating. Partnerships are possible. Second, collaboration at a distance required the development of new working methods and relationships. Another global corporation with which I am familiar has replaced most of its residential employee education and training programs with instructional materials on CDROM, notebook computers, and a toll-free international telephone number. Costs of training have been reduced by half.

Of course, the international community is not an integrated corporation, and should not be. However, the practical lessons being learned in the private sector would be invaluable not only to learning at a distance, but collaborating at a distance. How can this knowledge be tapped to the benefit of developing countries?

through new (and old) technologies, still emulates traditional didactic instruction: the teacher (or the computer) teaches; the students learn and are assessed. This can be efficient and effective, but it assumes a knowledge source and a knowledge receiver raising, as the Main Working Document suggests, the possibility of dependency relationships. International distance education is developing along these lines, such as the UK Open University's graduate business program.

Such programs are quite valuable, bringing the knowledge of rich nations to learners in transition societies. But the burden of adaptation and of knowledge use is on the individual learner. Programs of this kind add to individual human capital, but do relatively less to develop the social institutions through which knowledge is used. Could the international community, perhaps with UNESCO leadership, seek to help educators look sideways across national boundaries to develop distance education programs together, with knowledge from all sources? Can collaboration at a distance become a global reality?

Citizens of many nations in transition do not have access to educational institutions during the formative period of their lives, much less as adults. But they are likely to have access to radio and television. The digital revolution, cable distribution, and advances in satellite communication are vastly expanding the capacity of broadcast media to carry knowledge to even the most remote populations. International broadcasting is expanding rapidly and there is a shortage of programming. At the same time that the world contemplates electronic networks, it will be important to think through new partnerships that help broadcasters contribute to the exchange of knowledge between the citizens of developing countries. Important initiatives are under way, such as the Television Trust for the Environment, WETV in Canada, and others. The Economic Development Institute of the World Bank has begun producing documentary television series on development experiences as a contribution to South/South learning. Presently these initiatives are not well linked: helping to do so could be a natural role for UNESCO, given the organizations distinguished history in broadcasting development.

Putting knowledge to work will, I think, require some new thinking about human resource development. We know that the economic returns to investment in education and training come through productive use of knowledge and skills. We have, however, narrowly viewed this as a linear relationship: get educated, get a job. The evidence that knowledge is often wasted

IMPLICATIONS: LOOKING SIDEWAYS

In his exploration of the implications of new technologies for modem organizations, Nobel prize winning physicist Arno Penzias identifies 'looking sideways' as a key characteristic of organizations that use technology well to increase their effectiveness.[2] Lateral relationships in networks, facilitated by technologies, are becoming an essential feature of organizations for which knowledge is the main product. I believe this concept has important implications for each of the issues that I have discussed.

Most distance education, even when made interactive compels us to rethink this relationship. Knowledge and technology are both changing continuously. Lifelong learning, always needed, is now a reality in much of the corporate world. Many modern corporations now think in terms of 'intellectual capital,' which is the sum of human resources, information technology, lateral networks and client relationships. Could this concept help in building the capacity to put knowledge to work in developing countries?

I think it could. One of the practical implications for establishing lateral networks would be to build first on functioning national and regional networks of institutions, adding the technology linkages to facilitate collaboration in developing and expanding teaching and learning activities and materials. The four elements of intellectual capital could provide a framework for assessing the capacity building needs of such networks. The idea alone that relationships with clients form an important element of an organization's effectiveness has implications for all forms of public service delivery, including education.

In an era of declining official development assistance, sustained development of both national and international capacity to collaborate in teaching and learning will require high levels of efficiency. A 'network of networks' that enables all to learn from the experience of others could help avoid duplication of effort and also to avoid costly mistakes. To mention just a few of the present initiatives: the Economic Commission for Africa's program for telecommunications development, USAID's Leland Initiative to build Internet access in Africa, the Soros Foundation's similar work in the Former Soviet Union, and the World Bank's INFODEV program in which the Bank and the private sector are cooperating to improve launching pilot projects to establish international I both telecommunications policies and applications. The Economic Development Institute of the World Bank, is Internet networks in the FSU and with the African Economic Research Consortium for the purpose of developing and sharing knowledge.

In developing such a 'mega-network' we should be careful to look sideways. The international community can use the power of the Internet to regularly share information on their initiatives. At the outset, this is as simple as maintaining comparable windows on agency sites on the World Wide Web that report on networking activity, with hyper-links to other agencies. With an open architecture, this network could very quickly enable both national and international members ,to supply information and seek advice. It is also possible, though certainly not assured, that global corporations would share non-proprietary information through this network. Perhaps the development of this architecture and the identification of the initiatives that it could link would be an appropriate 'catalyst' role for UNESCO.

Part VIII

CLOSING CEREMONY

PLENARY

SPEECH

Yu. L. Ershov

CO-CHAIRMAN OF THE INTERNATIONAL PROGRAMME COMMITTEE OF THE CONGRESS
DIRECTOR OF THE RESEARCH INSTITUTE OF MATHEMATICAL AND INFORMATION FUNDAMENTALS OF EDUCATION AT NOVOSIBIRSK STATE UNIVERSITY
(RUSSIA)

Dear Chairman,
Dear Ladies and Gentlemen,
Colleagues!

I am glad that I have an opportunity to participate in this important and interesting Congress, I am glad. that I have an opportunity to speak before you. From numerous conversations with the participants in the Congress 1 know that many of them are rather pragmatic and they expect that some concrete problems will be solved at the Congress or, at least, they will be given advice and recommendations how to solve them. I hope that at least some of their questions have been answered during the plenary meetings, the meetings of the commission and the seminars.

Some of the pragmatically-minded participants do not like speeches on philosophic and general methodological problems. Let me apologise in advance before them, because I am going to speak about very general issues. I believe that the- most general issues can and must be discussed at such a large forum as this Congress. In the materials of the Congress such concepts as the pupil and the teacher, the expert and the person making decisions are used, but actually even particular person can play simultaneously a few if not all of these social roles. Thus. yesterday, for example, the majority of adult population of Russia look part in the Presidential elections and. consequently played the role of the people who make decisions I personally have always preferred the role of the pupil. Both at the Congress and while preparing for it I have been trying to understand the problems which are connected with the influence of new information technologies on education and their role in our lives.

The main working document of the Congress has enabled to focus the discussion on those queslions which are believed to be the most important at the present time. However, at this Congress 'be problems were discussed that were not mentioned in ihe working document and the urgency of which was realised only recently, I mean such brilliant speeches as those by V.G. Kinelev, Vice Chairman of the Government, Russian Federation, and Academician Blagovest Sendov, Chairman of Parliament, Bulgaria. Obviously, these problems are going to be among the main at the next Congress, which, I hope, will soon take place.

To formulate some of the future problems I would like first to consider one important concept. Such terms as «information age», «information society», have become quite common and are used to describe lhe coming 21st century. There have been a number of successful attempts to show what they mean. to describe this concepts using precise scientific terms I shall try to explain my understanding, giving not strictly scientific description of these important concepts.

Thus, let us imagine that a new continent has emerged on this planet. Let us agree to call it Infoland (nowadays such terms as cyberspace, *kiberprostranstvo,* and many others are used). I will refer to this new continent as Infoland. It is both beautiful and ugly. having Wonderfields, Disneylands and Las Vegases, having wells of wisdom comparable to the Lenin Library, the Congress Library, USA, the British Museum. On this continent there is all the beauty of ihe world and the masterpieces of art, the paintings from the Hermitage and immortal arias of the Milan Opera. On this continent there are also places where all information dirt is accumulated and it is spreading. There are certain diseases on the continent. One of them was mentioned in the report by professor M. Larijani from Iran who called it *"infomania".* It is very easy to get to the continent and it takes little time. there is no need to get a visa or the permission of the parents for children. To wander over the continent you need neither teachers nor instructors (by the way, here arises a new pedagogical problem). This continent is created not from material but from information. Academician Sen dov believes that lhe concept of information is fundamental in the same way as the concept of matter and energy. The information age begins, in my opinion, when such a continent emerges, and I believe that this continent has already emerged, that is the information age has begun I also believe that it came into existence not when the first computers were introduced, but when ihe global information networks having powerful information channels were introduced.

The emergence of the new continenti on lhe Earth is undoubtedly influencing and will continue to influence life of the whole planet. That is why it is so important to understand the nature of civilization on this contineni. Fortunately, there are at least «traffic rules and regulations» on the continent. We should be grateful for it to the specialists in network technologies who carry out in time technical protocols which enable to keep order on rapidly spreading highways of Infoland.

And what about law, morals, culture and philosophy on the continent? As the discussions indicate, including those conducted at this Congress, there have only appeared sprouts of these most important components of civilization. I think that alongside with a further development of Infoland the most important problem at the beginning of the information age is the creation of such a civilization on the continent that will help all the old continents on the Earth to use its many fruits to be able to create a just, free and prosperous life. This is the most difficult task. To build such a civilization is the common cause of the whole planet, the cause that will help to develop international cooperation and mutual understanding of all the nations and countries.

At the same time the solution of this problem is a challenge to education: *how to educate the new generation most efficiently for it to be able to live in the information age, to respect it*. In two reports, apparently irrespective of each other, in the report by Konstantin Kolin from Russia and in the report by Jose Valente from Brazil the term «society of knowledge» is used and what is more, both these reports contain a prediction or, I should say, an appeal to create an ideal way of development: the transition from industrial society or consumption society to the society of knowledge and I agree that in the society of knowledge the care of science and education, of acquisition of knowledge is the top priority for the state. I believe that it is in this very society that the above mentioned problems of creation of information civilization and education of the generation that is prepared to lead a successful life in two civilizations - a traditional one which exists on the Earth and handmade information civilization - can be solved most efficiently. Because Infoland is not a material continent, its geographic description is certainly neither full nor precise. Moreover, a rapid growth of the continent, irrespective of its location, would result and in a sense will result in the expansion,of the whole planet.

Let me use one more analogy or one more image. In the report by V.G. Kinelev it was it was emphasised that the most important gift of the 19th century to the 20th century is the understanding by the humanity of the notion of relativity. Speaking only about the theory of relativity by Einstein, it showed that we live not in the three-dimension spatial world but in the four-dimension spatial and temporal world. Now, I daresay, that the 20th century presents the 21st with one more dimension, that is informational. This dimension is not a unity, using a technical but quite common and intelligible term, it can be viewed as a hypertextual dimension. By the way, the 20th *century has not been long enough* to be able to understand rather fully our four-dimension world. I cannot say that everyone knows well, feels and understands what is the gist of it. Will the 21st century be long enough to understand even a greater number of dimensions of our world?

Summarising what has been said, one can arrive at the following conception: at this Congress new information technologies have been considered as new means to solve traditional education problems of adaptation of the coming generations to be able to live a successful life in the information age will come to the foreground. Let us hope that living in the information age, *in the society of knowledge, the humanity will* successfully solve all the problems it faces.

The original is presented in Russian

MANY QUESTIONS, A FEW ANSWERS

Jef Moonen

FACULTY OF EDUCATIONAL SCIENCES AND TECHNOLOGY DEPARTMENT
OF EDUCATIONAL INSTRUMENTATION UNIVERSITY OF TWENTE
(THE NETHERLANDS)

1. INTRODUCTION

Mister Chairman,
Ladies and Gentleman,

The theme of this Congress was: Educational Policies and New Technologies.

I am very grateful that the Russian organizing committee gave me the change to elaborate on this theme during this Closing Session of the Congress.

I have listen with great care to many of the presentations, and I was very impressed with their quality, their scope and their vision. Many questions were raised. In my presentation I will cope with some of these questions and try to give some answers.

To make sure there is no misunderstanding, when I speak about new technologies, I mean new information and communication technologies.

2. FRAMES OF REFERENCE

What I have experienced very strongly during this Congress, is that we need much communication in order to understand each other. Speaking different 'languages' is certainly one part of misunderstandings that can occur, but much stronger in this respect is the fact that we operate from different 'frames of reference'.

It was very strongly emphasised during the opening sessions on the first day (and repeated several times during the following days): the need to. be able to maintain our own cultural, ethical, personal and organizational identity. In other words, to be able to operate in the environment and the context we are familiar with.

This emphasis on individual identity and individual differences is strengthened by the current technology, which makes individual choices much easier. This is happening in education, but even much more strongly in the consumer market and our daily lives. Current societies emphasise the chance and the right to be different, and, more important, the opportunity to be different. This applies to individuals and to schools, as well as to educational systems at large.

As there are many people, many schools and many educational systems there are also many individual differences and therefore many frames of reference. Those frames of reference are the result of our culture and our personal development. It would be wrong to even try to make them equal.

3. CHAOS OR STRUCTURE?

However, when every individual, each school, and each educational system wants to be 'different', chaos will be the regular pattern and conflict will be the result. So, how to deal with this dilemma?

The solution is that we should agree upon the goals of what we want to accomplish with our schools and our educational systems. And from those goals, criteria should be derived in order to evaluate our actions.

This reasoning is basic to my thinking. This is my approach from which I try to answer the fundamental question that should be raised by all of us: why are we using technology in education?

4. WHY USE TECHNOLOGY IN EDUCATION?

'Why are we using technology in education?' is a question we all should deal with sooner or later. There are at least three answers to this question:

a. because the technology is there,
b. because we believe that technology is good for education,
c. because there is empirical evidence that technology makes education better.

It depends on our own frame of reference, which position we will take. Please reflect for a moment and make up your own mind.

If I had asked the participants of this Congress to answer this question, my guess is that 30 % would choose for answer one, 50 % for answer two, and 10 % for answer three. And to keep in pace with the Russian tradition, 10 % would choose for 'none of the above'.

Whatever our answer, we should live up to our choice. This means that we have to make sure that when we support the use of technology in education, we have to be convinced that the criteria, related to our particular choice, are being fulfilled.

Let us overview each of the choices in more detail.

If the answer is 'because the technology is there', the criterion is very simple. Technology is all around us and that can very easily be verified. When you made this choice, however, you have to realise that you will have a difficult time to keep up with the very fast changes of technology. What is there today, will have changed tomorrow. It will not be possible to continually implement the permanent changes of technology in education. After a while, you will have to give up. Therefore the first answer to the question cannot be sustained. Maybe it is acceptable as an answer in the beginning, but gradually, the answer should evolve to one of the other two.

When your choice was: 'because we believe technology is good for education', we have to derive a criterion that operationalises 'good' education.

What is considered 'good' education is very strongly determined by the frame of reference we use. 'Good' education in one setting could be interpreted as 'bad' education elsewhere. Therefore there are no universal criteria to describe what 'good' education is. Consequently there is no absolute way to determine if using technology is indeed 'good' for education. 'Good' can only be operationalised in a particular situation, with reference to a particular frame of reference. The fact that the derived criterion will be a specific one as well, does not dismiss us from the obligation to check if using technology in our particular situation fulfils the promises put forward by the criterion.

In the hypothetical survey to which I referred, my personal answer would be in the third category. My point of view is that we should use technology in education assuming there is empirical evidence that indicates that technology makes education better. And as this empirical evidence is still very rare, I am constantly looking for applications of technology that produce clear indicators of improvement of the educational system I am working in.

There are many perspectives that can be considered when we talk about better education. 'Better' can refer to the learner, to the teacher, to the institution or even the educational system as a whole. There are also many dimensions of 'better' education. We can think about better performance of the learner, better attitude of the learner, better motivation of the learner, improved working conditions for the teacher, lower workload for the teacher, better financial conditions for the institution, better organisational conditions for the institution, and so on. 'Better' is the criterion to evaluate if using technology in education is adequate and appropriate.

5. EDUCATIONAL PRODUCTIVITY

As has been said before, 'better' can be operationalised in many different ways. In order to be able to cope in an easier way with this multidimensional criterion, I suggest using another concept: educational productivity. In this respect I do not mean productivity in the capitalistic sense whereby, based on competition, output is being maximised regardless of the consequences for the input, and in particular the people and the environment. When I talk about educational productivity I mean productivity as an expression of the optimal use of means, taking into account the limited resources of schools and educational systems, taking into account the need for a natural evolution in human change processes, and taking into account the care for the environments in which we operate, including our cultural and historical heritage.

Educational productivity maximises the effectiveness given a fixed amount of input, or minimises the costs given an acceptable amount of output. Optimising educational productivity implies that technology is used where it can provides its strongest effects: (a) to support communication, and (b) to provide access to information.

Taking into account the very different environments that exist all over the world, specific criteria related to educational productivity will be very different as well. This is certainly the case comparing developed countries with developing countries. In developed countries criteria for using technology could be to stabilise the output of the educational system while reducing the costs (the input). In developing countries criteria for using technology could be to expand the educational system (the output) while keeping the costs (the input) stable.

Summary

It is very important to realize that different environments and different frames of reference lead to different criteria, and therefore to different ways of applying technology in education. Being different, however, does not imply, there should be no criteria.

6. EDUCATIONAL POLICY AND NEW TECHNOLOGIES

In the remainder of my talk I will give an analysis of the new technologies in relation to their use in education.

When implementing technology a number of issues have to be taken care of:

a. the hardware infrastructure of a school,
b. the network infrastructure of a school,
c. the provision of educational materials and software,
d. the teacher or professional training,
e. the integration of technologies in the school curriculum.

For each of these issues, I have chosen one topic that I consider as typical and crucial and express it as a bipolar choice. For each topic I will give you my opinion and point towards policy implications.

6.1. Hardware

Computers labs with PCs or Laptops, input/output and communication devices?

It almost has become a kind of tradition to start the introduction of computers in education with the instalment of computer labs. Computer labs however become very fast the 'private' domain of a few (computer science) teachers. In addition, using computer labs create large logistics problems. Therefore the productivity gains created by such provisions remain limited to the few subjects areas that are able to make use of them. A better solution is to have available a transportable set of powerful laptops that can be moved from classroom to classroom. Each teacher should eventually have his own laptop. In time, such laptops should be replaced by (privately owned) palmtop with CD-ROM drive and/or network computers that can be taken home by the learners, or interactive television that makes use of two-way cable systems. The strategy of policy makers should be that the hardware used by teachers and learners should become privately owned by them, as soon as this is financially feasible. School provisions should be focused on input devices (such as scanners, digital cameras, CD-ROM players in order to present multimedia), output devices (such as projection devices in classrooms) and telecommunication facilities (to connect schools to external networks).

6.2. Network

Internet or Local area network?

Given the discussion about the Internet and its possibilities, it is obvious that it should be the goal of each school to become connected. Given the vast amount of information available on the Internet, significant productivity gains can be achieved in terms of reduction of preparation time of teachers and in terms of reducing costs of learning material by learners. Eventually, in addition, schools should be equipped with an Intranet system, which is a local area network server supporting the same features as the Internet. Such an approach could reduce the communication costs to the Internet significantly in that interesting topics from the Internet and in particular from the World Wide Web can be downloaded onto the local server and used as local applications. This approach can be very productive as Internet contact time can be reduced and also the teacher can better structure and adapt the materials.

6.3. Educational Materials

Quality of materials or Quality of teachers?

Much has been said about the 'lack' of quality of electronic learning materials, such as educational software. However, given the great variety of 'frames of reference', in particular curricula and teaching styles, it is very difficult, if not impossible, to produce electronic learning material that fits many frames of reference at the same time. In addition, one should realise that producing educational quality is an activity that results from the combination of the teacher with his learning material. Just as it is a cook who produces a fine meal given he has sufficient ingredients, it is the teacher that has to use materials and produce a fine lesson with them. Productivity gains therefore are not to be expected from 'high quality' educational material, but from quality materials that can be shaped by the teacher in order to fit his own teaching styles and goals.

6.4. Professional Training

Basics of informatics or Educational technology and quality control?

Teacher training about the use of technology in education is a subject of much discussion. Many aspects can be mentioned in this respect. It is the expectation that teachers will use the potential of the Internet to communicate with each other, to exchange information and to collect examples and materials to be used in their own lessons. As been said before such activity can contribute to the productivity of their actions. However, a crucial variable in this respect is the potential lack of quality control. When teachers receive materials from others, such material has being produced in other frames of reference. It is up to the teacher to evaluate those materials, and decide if such materials are useful for his own activities. A major part of professional training should therefore be spent on developing an expert sense of quality control. Training teachers in instructional, curriculum and instrumentation design, as well in evaluation techniques, could provide teachers with the necessary basics.

6.5. Integration into the Curriculum

Computer literacy or Integration of computers into the curricula?

How much computer and telecommunication literacy should be taught in school as a regular subject area? It can be observed that learners have no difficulty with these issues. It are the teachers who feel uncomfortable with them and therefore refuse or delay integration of technology in their curricula. Many productivity gains can be achieved when technology is adequately and appropriately used in curricula (as drill-and-practice, as simulation, as tutorial, as data-collection device, as a drawing tool, and so on). Therefore it is necessary however that teachers are supported to get over the first threshold. The suggestion by Dr. Semenov, whereby he suggested pairing two teachers (an informatics teacher and a subject-area teacher) at the start of a course in order to overcome the technical and psychological difficulties of the subject-area teacher, is worth considering.

There many more topics to be discussed, but due to time limitations I cannot go into more detail.

7. SUBSIDIARITY PRINCIPLE

In the European Union much discussion is going on around what is called the 'Subsidiarity' Principle. This means that everything that can be handled well at the country level within the community, should not be dealt with by the European Commission. The reason for the application of this principle is very simple. Because of the diversity in each of the countries, the countries themselves are best suited to decide what to do when dealing with specific issues.

The same is true in education. Therefore, as a general principle, let the appropriate educational level decide what is most appropriate to that level, also in terms of using technology. In each case, however, all of our decisions should be driven by the same goal and by the same criterion: using technology to improve educational productivity.

In this respect UNESCO should not do what can be done better by others, such as the creation of educational materials. What UNESCO should do is what national authorities cannot do: provide supranational opportunities for co-operation and information dissemination, such as described in the Global Project presented by Dr. Stanchev, and connect people of different nationalities for better mutual understanding.

The major power of technology lies in its capacity to support communication and to give easy access to information. UNESCO should concentrate its efforts in this area by exploiting these two potentials. UNESCO could transforms itself into a focal point of telecommunication facilities between nations. Instead of having physical meetings, creating major organisational difficulties, UNESCO could create, when appropriate, virtual (video and audio) conferences whereby participants in each country could stay at home and meet in a central location in their country. With the vast amount of information of the UNESCO library and resources online, such an approach could significantly rise the effectiveness of a conference and, most probably, result in a serious reduction in costs.

8. CONCLUSION

Ladies and Gentleman, this is the end of my talk. Much more could be said, but I hope I have said enough to give you an impression of my frame of reference. And I do hope that it will make you think and reflect about yours.

Finally, I want to thank professor Yuri Ershov and all of my colleagues in the International Programme Committee for their availability and their perseverance with this committee. It was very nice to work with you all.

Thank you.

PROSPECTS OF DEVELOPMENT OF A RUSSIAN INFORMATION INFRASTRUCTURE AND ENTRY IN WORLD INFORMATION COMMUNITY

A.S. Golubkov

THE CHAIRMAN OF COMMITTEE AT THE PRESIDENT OF RUSSIAN FEDERATION ON THE INFORMATION POLITICS

PROSPECTS OF DEVELOPMENT OF A RUSSIAN INFORMATION INFRASTRUCTURE AND ENTRY IN WORLD INFORMATION COMMUNITY

In last decades of the XX century the world community enters the new stage development - information community. Russia nor costs in party from global world tendencies. The changes, which occur in the world, are accompanied in Russia by great changes in economic, social and political spheres. Much vary and information attitudes in society. In the Russian market thousands firms, delivering modern hardware-software means of the conducting world manufacturers now work. A number of Russian firms are engaged by assembly and delivery of computers. The inventory materials for their manufacture act mainly from boundary.

The majority of the large Russian companies is prepared to the customers by the systems network decisions on foreign catalogues and develop separate components of the software, but also deliver system program environment with the using of own development. In Russia are function the decades of large computer networks of general using. Among them it is first of all possible to name «RELCOM», «ROSPAC», «IASNET», «SPRINT», «INFORTEL», «ROSNET», «TECOS», «SOVAM TELEPORT», which function on the base of protocols TCP/IP. Practically all of them are using in their work the import network equipment. Therefore one of the main problems here is to expand manufacture of means of computer science on the basis of international cooperation.

The computer networks, functioning in Russia, have sluices for output on foreign networks, including in Internet. Among other Russian units Internet follows to allocate education network FREENet. It unites the organizations of RSA and educational institutions. The network Internet is accessible also through service of e-mail from such networks, as BINET, DECnet or Sprint, which uses the other systems of the protocols. Thus, in Russia now already there is the number of elements, necessary base for creation of a national information infrastructure.

At the same time the condition of information in Russia is characterized and beside of unsolved problems: by backlog in relation to countries - leaders in manufacture of own element base, means of computer facilities and communication, insufficient level computerization of various spheres of activity of a society and development of the market of information services.

Despite significant expansion in last years of the information market, the opportunity of access to information is still limited. The majority of the population receives the information in traditional kind - printed editions, radio, TV.

The requirements of economy, successful making of reforms require perfection of a national information infrastructure of Russia (NIIR), overcoming of barriers (legal, economic, technical) for free movement of the information and creation on territory of Russia of uniform information space.

The decision of problems of national information infrastructure of Russia assumes outstriping development of its(her) telecommunication environment as bases of open interaction of information systems according to international model OSI.

Obvious and important condition of development of national information infrastructure of Russia is compatibility of soft - technical platforms of computer and telecommunication services. The basis for maintenance of compatibility could be served by development and realization of open interfaces, the specifications of which should be easily accessible to all suppliers and users of services.

Not less important is the decision of a problem «toleration» of software. Toleration as ability of the applied programs and data to be moved without essential updating on more than one type of computer platforms and, accordingly, operating systems, will allow to a society to save intelligent labour of a plenty of the experts, will create a basis for faster development of an infrastructure.

The development of national information infrastructure of Russia requires creation not only technical and technological base of information, but also account political, social and economic aspects of Russia. It results, as a rule, in essential compilations of western decisions.

Overcoming monopoly of state and commercial structures on information resources and services is also necessary. It is for this purpose required in legislation and economic gears to realize a principle of liberalization of the information market.

Proceeding from specified parcels, it is possible to formulate the following purposes of national information infrastructure of Russia as bases of formation of uniform information space of Russia:

1. Maintenance of the constitutional rights of the citizens on information;
2. Creation and maintenance of a society necessary for steady development of a level of information potential;
3. Distribution of new information technologies to all spheres of activity of a society and person, first of all in education, public health services, science, social maintenance;
4. Increase high speed, stability and efficiency of activity of bodies of state authority, local self-management, subjects of managing;
5. Integration with world information space.

The development of national information infrastructure of Russia will be carried out on basis:

- Modernizations of a domestic microelectronic and computer industry, creation of conditions for development of the domestic market of information, progress of Russian competitive means of information on world markets;
- Encouragement of domestic and foreign information technologies;
- Development of a primary network of communication, especially at regional level, construction of information superhighways:
- Perfection of the legislation on use of information and telecommunication systems by the physical and legal persons, protection of the intelligent property, counteraction of computer criminality;
- Maintenance of compatibility and interaction of systems and networks in view of international systems standartization;
- Providing of access of the citizens to open state information resources, information on activity of bodies of state authority and local self-management.

The quality in market of means and systems of information should be provided by creation of system of organizations for licensing and certification of means and systems of information and information production, including on safety.

Federal and local systems and networks of the tax, processing and the distributions of the information should render various information services to the population, enterprises and organizations on the basis of state information resources. With this purpose we are going to accept the legislative and normative sertificates, determining the rights and of a duty of the officials on formation and to use of state information resources, to decide economic problems, connected to their use.

Formation and the development of an information infrastructure requires significant expenses, designed for a number of years. With the purpose of rational distribution of resources it is supposed step's development of national information infrastructure of Russia and creation pilot zones.

1-th stage (till 2000)

Creation of an infrastructure in several regions of Russia, the most advanced on a level of development computerization and of communication, with improvement on them of principles of construction and functioning of national information infrastructure of Russia, organization of «sluices» for access of the Russian users in international networks.

The 2-nd stage (till 2003)

Creation of information superhighways: Copenhagen - St.-Petersburg - Moscow - Far East; Palermo - Istanbul - Novorossiysk - Moscow with connection of regions in accordance with readiness. It is very important to supply wide informing of a public on opportunities and information services, perfection of system of training and increase computer education of the users.

Creation of a modern information infrastructure - very expensive measure. In such countries, as USA, on these purposes are spent many billions of USD per year. Certainly, main part of work on development of national information infrastructure of Russia will be carried out by private sector as the most dynamic and interested user and supplier of information services. Sources of financing of development of national information infrastructure of Russia will be also means of the federal budget, budgets of regions and local budgets for creation of regional structures of national information infrastructure of Russia.

The main problem of state structures - creation of conditions for investing in national information infrastructure of Russia, attraction of consolidated means of major concerns, industrial companies, banks etc. There could be used also the target loans and other forms of attraction of means from population and commercial structures. The certain prospects are available in Russia and for foreign investments and credits.

For decision of problems in the field of information relations in February 1995 the Federal Law «About information, informatics and protection of the information» is accepted. The specific measures have found reflection in number of the state programs. The federal target program «Informatization of Russia», «The Concept of Formation and Development of Uniform Information space of Russia and appropriate information resources» and number of the documents on support of various directions of information were prepared. The projects and programs, directed on development of national information infrastructure of Russia, including such as «A Business network of Russia», «The National Telephone» and other wilt be realized.

International information exchange and cooperation. The leading countries of the world work international information infrastructures out. At various levels the projects of creation of a global international information infrastructure are discussed.

Russia and partners are interested in international information exchange. The integration of Russia as of the equal in rights partner in international information community will allow:

- To receive access to information resources of all countries (members);
- To develop networks of communication and system of information as on federal, and on regional, local levels;
- To ensure progress on world market of domestic high technologies and «know-how». It is a lot of useful it will give to the partners of Russia in development of vast markets and resources.

However, except political will, the high-grade integration of Russia in global information community requires the decision of problems, connected to technological and legislative questions, touching use of computer technologies and networks of telecommunications, protection of the information and information safety. Therefore the entry of Russia in global information community will be evolutionary, in view of experience of other countries.

By virtue of that the rates of development of an international information exchange will be determined, mainly, activity of private sector, including foreign, to state bodies in this period follows to give attention to creation of an international legal mode, ensuring an information exchange and application of the sanctions to the suppliers of off-standard means of telecommunication information products.

Now the legal basis of an international information exchange is developed insufficiently. Acceptance of the acts in this area in Russia and appropriate international agreements is required.

The successful development of an information exchange is possible only that condition of maintenance of protection of the rights of the intelligent property would be provided. In this area the situation is bad even in advanced countries. That concerns to Russia, the state bodies at last 3-4 year have undertaken a number of measures on protection of the rights of the developers of the computer programs, databases and other information resources. Therefore the situation recently begins to be stabilized.

Other aspect of a problem - protection of information resources as of objects of the property. The significant part of information resources according to working rules of law is not referred to objects of protection of the intelligent property, it appear legally unprotected.

The heaviest complexities cause questions of unauthorized access to confidential information of computer networks. These questions closely adjoin to problems of personal data. We have developed system of the legal sertificates and measures on protection of information resources.

It is clear, that the realization in today's conditions of a principle «free input» of information resources for all participants of an international information exchange results in reception of unilateral advantages by advanced countries. Besides the payment acceptable to advanced countries for using by network resources frequently appear inaccessible for Russian users. The factor, rendering adverse influence on Russian economy, can become non-adecvation of an information exchange.

The ability to interaction of information systems, using a plenty of the various equipment, is caused by development of many global standards. The development international standartization in sphere of information will be realized within the framework of work, conducted under aegis of joint Technical committee CTK «Information technologies» and some European bodies on standartization of IT. Russia participates in this process through Technical committee TK22 «Information technologies».

There are the problems, connected to humanitarian questions. New information technologies, the systems multimedia, virtual reality, remote work and training change an image of life of millions of the people. The mass consumption bad of information services of a type porno of videofilms, video conference, games, renders adverse influence on consciousness, especially of youth. The international information exchange aggravates these problems.

Important for us is the cooperation to countries of CIS. Integration processes, occurring in these countries, have caused need for agreed development of national information infrastructures of country of CIS.

According to decision of coordinatory-advisory Committee of CIS creation of Incorporated system of an information exchange between state-participants of CIS, Interstate system of the legal information for countries of CIS is carried out.

In November 1995 the Council of the Heads of Governments of countries of CIS has accepted the decision on formation of uniform information space of Commonwealth of Independent States.

And, in summary - main directions of development of an international information exchange. For development of an international information exchange and the cooperation are necessary for making active work of international organizations on following directions:

- Perfection of legal protection of information resources, including protection of the intelligent property in open telecommunication systems;
- Formation of international arbitration information court on disputed situations in international information exchange:
- System engineering of the international standards, first of all ensuring International interaction and information exchange;
- Formation of system international sertification program and means;
- Creation of favourable economic conditions for international information exchange, first of all in the field of science, education, small business.

REPORT ON THE WORKSHOPS

Ivan Stanchev

DEPARTMENT OF EDUCATION,
UNIVERSITY OF TWENTE (THE NETHERLANDS)

In his report, Prof. Stanchev pointed out that, in addition to the plenary and commission sessions, *12 educational-and-practical workshops* were conducted within the Congress framework on the following topics:

1. Information Superhighways and Education *(Part I:* Prospects and problems of common global and regional information space for education; *Part II:* From Information Literacy to Information Culture).
2. The Psychological-Pedagogical Impact and the Medical Consequences of the Application of Modern Information and Communication Technologies.
3. The Software Environment – A Perspective for Effective Involvement.
4. Transfer of Knowledge and Skills through Information and Communication technologies.
5. National Policies - Transfer of Technologies.
6. Individual Distance Training.
7. Analysis of UNESCO/IFIP (International Federation for Information Processing) Documents published in 1994-1995 *(Part I:* Informatics for Secondary Education - A Curriculum for Schools: *Part II:* A Modular Curriculum in Computer Science).
8. Logics, Informatics and Education.
9. Information Technologies and Humanities Education.
10. Development of Pre-University Education via Modern Information Technologies and Methods.
11. Medicine: New Approaches to Knowledge Acquisition and Improvement.
12. Forming Integrated World Data Bases and Knowledge about Planets of the Solar System and Their Use in Research and Education.

The workshops were chaired by leading experts, academics and researchers such as: David Walker (UK) - DW Associates consultant; Peter Waker (South Africa) - IFIP TC3 - Computer Olympiad consultant; Alain Meyer (France) - Director of Centre de Tele-Enseignement, Conservatoire National des Arts el Metiers (CNAM); Tom van Weert (The Netherlands) - Director of the Informatics School under the Mathematics and Informatics Department of Ni-megen University, 3.2 IFIP Working Group Chair; Har-ald Schutz (Germany) - Deutsche Welle Internet associate; Konstantin Koline (Russia), First Deputy Director for Research of the Informatics Institute under the Russian Academy of Sciences; Yuri Afanasiev, Rector of the Russian State Humanitarian University; Alexey Semenov (Russia), Deputy Chair of the Moscow Education Department, Rector of the Moscow Institute for Professional Upgrading of Education Workers; Nikolay Yevtikhiyev (Russia), Rector of the Moscow Institute for Radio Engineering, Electronics and Automatics.

Over 200 experts in various fields of education and computer science took part in the worshops.

Prof. Stanchev drew attention to the great number and diversity of the opinions voiced at the sessions and of the proposals to be incorporated in the work on the final documents of the Congress.

The results of the workshops were summarized as the following conclusions:

- Information and communication technologies have brought to life new forms and methods in education and promoted open and distance education.
- Effective implementation of new information and communication technologies in education requires improvements in the system of teacher pre-service and in-service training, including the development of social programs and courses.
- It is necessary to coordinate the efforts of instructors at the higher and secondary educational establishments applying new information technologies in the teaching process with those of the hardware and software developers.
- The information and communication technologies have a significant role to play in reforming the education systems, particularly in the developing countries and those undergoing a period of transition.
- The implementation of information and communication technologies can change the content and assimilation of the knowledge taught, as well as promote the development of individually oriented education.
- Support on the part of the governments, international and regional organizations is essential in order to extend the emerging communication networks 'and superhighways to the institutes of education.
- Conditions should be provided .within the framework of international cooperation in education to promote the exchange between schools and individual instructors of information and of the programs for learning new information technologies. Telecommunication technologies can be a major factor in the achievement of this objective.

The reports on the results of the workshops contain many practical proposals on implementing international research projects which could be of interest to UNESCO and its institutes related to education and the information science..

The original is presented in English

REPORT ON COMMISSION I

Katerina Martcheva

DIRECTOR OF THE HIGHER SCHOOL FOR FOREIGN LANGUAGES (BULGARIA)

Ms Katehna Martcheva, President of Commission I, pointed out in her report that the discussion of the trends, introduction experience and the implementation of new information technologies (NIT) in education covered the main topics of the Congress.

When the topic «Learners» was discussed, the participants analysed the basic stages of applying NIT at various educational levels, examined the instruction in computer science course using the experience compiled by general secondary schools in Russia and Switzerland, and identified the difficulties involved in the development of computer tutorial programs for various disciplines and in providing the learners access to new technologies.

The application of NIT can significantly change the role of the *tutor.* The reports pointed to the need to organise the course that would make it possible for the teachers to effectively apply NIT in the teaching process. There is also a need for educational computer networks available both to the teachers and learners free of charge. Besides, to ensure a better effect from the application of teaching networks, they should incorporate the tutorial programs worked out by the teachers, since they are best suited to be the pioneers, innovators and initiators in a wide-scale application of NIT for educational purposes. Interaction and mutual assistance of the teachers can be greatly enhanced by the use of computer networks. Due to computer networks, the teachers have an access to comprehensive information and resources and can choose the programmes best suited for their specific curricula and tuition subjects.

It was stressed that the implementation of new information technologies should be focused on *pedagogical rather than psychological aspects.* The latest and traditional *technologies* should be mutually complementary if the most suitable interactive educational materials are to be developed.

As was pointed out, there were some great expectations connected with the possibility of applying computer information systems for achieving social and economic objectives. However, since the research so far conducted into the possibilities and implications of applying NIT in various fields is still not adequate to the task, a more profound analysis is required of the ranges and limitations in the implementation of these technologies.

Other subjects discussed within the framework of the Commission's work were the problems encountered by the teaching and learning humanities in the new informational environment. University education places a great importance on informational independence and informational freedom. In fact, informational freedom is the foremost objective of the education inhumanities. The participants pointed to the need for applying a more humanitarian character to the education in natural sciences, and engineering/technical fields.

The use of multimedia, as was stressed, though providing the required knowledge and information resources, cannot adequately substitute for the learners' and teachers' interaction.

Since the institutes of education lack the possibilities for producing tutorial software on their own, it would be desirable for UNESCO to coordinate at the international level the efforts aimed at providing software for schools, that is to say, to promote its legal use by schools and the development of computer programmes specially designed for application at school.

The speakers presented data on the application of new information technologies in a number of countries. The French educational system was described to demonstrate the principal strategies adopted by the French Ministry for Education to achieve the following objectives: modernisation of educational management in schools, introduction of respective NIT into the technical and vocational training, measures necessary to ensure the application of NIT as the teachers' aid in various disciplines, the use of NIT in general secondary schools via Internet, making computers available to the learners.

Other problems involved in the implementation of new information technologies relate to the countries' inequality in respect of availability of required technologies, the system's instability, and the teacher training. As was pointed out, every institute of education should have free access to computereducational resources.

The speakers stressed the need for working out a more clear-cut NIT classification and terminology for educational applications.

Attention was drawn to IFIP contribution to the development of NIT and to their applications in teaching and learning processes attained due to IFIP's close ties with UNESCO and to the convention of conferences, seminars and consultations.

The materials on the pedagogical and psychological impact of NIT on the teaching process, translated into several languages, as well as the modular computer science curricula for the higher and secondary schools, could significantly assist the effort to apply new information technologies at school.

A proposal was put forward on the development of an international programme for legislative support to the system of distance education and for obtaining government licenses and certificates at the national and international levels.

In conclusion, Ms. Martcheva thanked the Russian colleagues for their good organization of the Congress and the rich and interesting cultural program organized for the Congress participants.

REPORT ON COMMISSION II

Gerald McConaghy

WINNIPED (CANADA)

Ladies and Gentlemen,

Our Commission deliberations on technology and education can be summarized as having dwelt on the following: culture and language, equity and accessibility, the role of the school in a knowledge-based society, teacher training and the sharing of information. I shall speak briefly to each of these.

Culture and language. It was felt that technology should be an instrument that enhances language and culture. Some concern was expressed about the Internet. While it provides fast and easy communication among users and provides limitless information for young people on any subject, its dominant language is English. This is worrisome for many countries who wish to maintain and enhance their language and culture. Internet usage is expanding rapidly and young people of all languages wish to use it. How can the Internet remain a facilitator of communicating and yet not undermine languages and culture? We did not arrive at any solutions but raise the question as one needing serious study and action.

Equity and accessibility. There are major differences in the funding of education and of technology from one country to another and, indeed, from one region to another within a country. This means that the schools in richer countries will have more computers and greater access to technology than poorer countries. It was pointed out that the problem is further exacerbated by the continuing cost of new information technology. As one speaker reported, costs are not going to diminish over time; in fact, they are likely to go up. Equipment wears out, new equipment is needed, new software, etc. What are the ways to ensure some reasonable level of equitability for new information technology among countries?

The Role of the School in a Knowledge-Based Society. Our Commission kept coming back to the role of the school as we move into a knowledge-based society. How must the school change? What kind of curriculum., particularly for information technology, should it have? What is the role of teachers and other professionals in helping students use new information technology? For our Commission just as important was the question: What is the role of the community in helping the school prepare young people to enter a new era dominated by communications and knowledge? It was felt that the school cannot be isolated from the community. It will be only through partnerships between the school, parents, business, etc. that the school will be able to carry out its mandate and that a society, committed to learning will develop.

Teacher Training. This follows from the role of the school. Our Commission felt that there needs to be new teacher training models which take into account the new information technology. Teachers need to be equipped with instructional skills to use technology as a pedagogical tool to help young people improve their learning. Teacher training is needed at both the pre-service and in-service levels. With in-service, much of it can be delivered at relatively small expense through on-line training as teachers continue their work in the classroom.

Sharing of Information. Because of new information technology, distances between countries, institutions and individuals have evaporated. There is now a need to share information as to what is happening in education and in research on the use of information technology. Each of us can benefit by being aware of and reviewing the work that others are doing. Mechanisms need to be found to help us in this sharing so that we are enriched by it.

Mr. Chairman, we spent some very productive time in our Commission. We had representation from many countries expressing many different views. I was impressed with the common interest that we all shared in trying to promote new information technology as an important tool to help young people learn.

Thank you for your attention.

REPORT ON COMMISSION III

Alexey Dovgyallo

UNESCO/IIP RESEARCH AND TFAINING CENTRE,
V. M. GLUSHKOV INSTITUTE OF CYBERNETICS
(UKRAINE)

Dear Chairperson,
Ladies and Gentlemen!

I would like to begin with a general impression from the work of our commission and the Congress.

On the one hand, it has been a very professional Congress. I have been in educational technologies for more than 30 years and it has been very interesting for me to listen to the plenary reports as well as to reports and presentations at the commissions.

On the other hand, what we have heard is not merely theoretical work, it is work that may become a good basis for practical plans of national programmes for educational informatization in national commissions and other institutions charged with implementation of new technologies in education.

Distance education dominated the discussion at the 3d commission. The group of Russian reports should be specially marked out.

The commission discussed the importunate issue of theoretical principles of information technologies in education. Prof. Larijani (Iran), Ukranian experts and some others made very interesting reports on this issue.

The commission also discussed the idea reflected in the recommendations, about three groups of countries defined by UNESCO, that is developing, developed countries and countries in transition. It is true that each of these groups of countries has its own specific features and should be regared separately.

I would like to mention Mr. Kalimba wa Katana, Minister for Higher and University Education and Scientific Research (Zaire) among the speakers. He expressed interests of African countries in informatization of education and prepared substantial recommendations on that account. I hope they will be included in the draft document that we have received.

Mr. Don Ferguson's report had a very important issue common with the key note speech made by Congress Chairman Kinelev. He suggested that Technology should be added to the list of fundamental disciplines, then communication technologies will occupy their proper place.

One more importante issue discussed at our sessions and put into the recommendations. I mean setting up of UNESCO Institute for Information Technologies in Education which is planned to be open in Moscow. We wish this Institute to have short term analysis of whether this or that educational technology is prospective or not as one of the priority activities. Results of such work will help to save a lot of means and efforts of specialists in various countries. Certainly these analytical reports should go through UNESCO so that they received exertise at the highest level, and countries and groups of countries could use them for practical purposes.

I will not use any data as illustartion, the Congres Secretariat has them.The only thing I would like to advise on is to take into account when writing the final list of recommendations, the documents that were submitted to the commission and to publish them either as appendices or some supplement.

On behalf of our commission, its experts, scholars, administrators I would like to thank organizers of the Congress, the Russian Organizing Committee and wish that such Congresses be held not once in 7 years, but every two or three years.

The original is presented in Russian

SUMMARY REPORT

John Foster

RAPPORTEUR GENERAL
(UK)

It is my task to summarise 45 hours of meetings in under 20 minutes.

First, I have to say how impressed I have been at the high standard of presentation that we have had in the last week. Some of it was even addressed to the correct theme of the day and even sometimes directed at the correct commission audience! But even where it wasn't, the content has been almost entirely on one of the themes of the Congress and this I find rare these days, as so often people come to Conferences and deliver a paper on a favorite topic, regardless of the Conference's theme. Perhaps we were lucky and we chose your favorite themes as our themes and so there was no conflict.

Last night I read through the speeches from the last day of the 1989 UNESCO International Congress in Paris. As Mr. *Colin Power's* speech predicted on the first day of this Congress, we have been talking about and agreeing with much of the same matter as you did in 1989. Then, as now, you were calling, amongst other things, for more research projects to give us a greater insight, tools to lessen the gap between the developed and developing countries, a sensitivity to cultural differences and a resistance to any international homogenisa-tion of education. The main difference is that today, as Mr. *Kinelev* said in his speech on Monday, we have the possibility, through the Internet, of creating a global information system with multiple possibilities for the spread of knowledge and for research and as Mr. *Rockley Miller* said on Tuesday, very fast, (and Victor Hugo said before him, rather more slowly I guess) "There is nothing so powerful as an idea whose time has come".

So we now have a powerful tool and have one less excuse than the 1989 delegates had and we must hope that my successor in the next world Congress will be reporting more progress than I can on these issues.

But then we have also had this week many warnings about this tool. The warning as to the potential damage from the information ecology (cited by Mr. *Sendov)* to the cultural ecology of the world has been being echoed throughout the Congress. The rapid adoption of a sometimes anarchic Internet, as well as possibly acting for the benefit of the world, could also bring about ruin to cultural diversity. I liked Sendov's image of computer pollution being potentially to our age what the factory chimney was to the industrial age.

Mr. *Matsumae's* analysis of the needs of Higher Education and his reports of activity in his one gave us hope and examples of benefits and potential benefits of the computer age. He also began, what has been a trend throughout the Congress, to talk about opportunities for sharing across boundaries, in cultural groupings, and, where appropriate, beyond them. Mr. *Hafaiedh* also talked of sharing and of the globalization of learning and gave a historical perspective on the development of learning pedagogies - and so we were launched into the first Commission Session for our first theme, «The Learner».

I have to say, that most of the first theme Commission papers were not, as they should have been, about Learners, and we had the problem in all rooms with speakers overrunning their time and therefore, of no time for discussion. I hope you found that this got better during the week. The Rapporteur, and UNESCO staff met with me each day to report on the activity of the commissions and the recommendations from them and it was noticeable each day that they reported more debate and more recommendations for further activity. You will have by now the draft recommendations and declaration document in French, Russian and English and you will see that there are many suggestions. You may find that your recommendation has been reworded. This is because, with so many, we have tried to roll them together to make composite recommendations. You may also find that your recommendation is not there at all. We could not include individual people's recommendations unless there had been some opportunity for them to be debated and for some consensus reported to me by the Rapporteur. I am sorry about this, but of course this does not stop you making your recommendations, perhaps through your governments, to UNESCO, through the usual channels. I will talk more about the recommendations later. And so we came to Tuesday and the theme "The Teacher" in the morning and "Technologies" in the afternoon. A superb example of the use of the Technologies for the benefit of Teachers was given to us, in the first plenary of the day by *Kumming Qian,* showing us how the Television Teachers' College of China was meeting a huge problem of underqualification of teachers with spectacular results. And this you will remember was followed by my good friend *Alexei Semyonov* with a characteristically well prepared presentation of some of the problems and solutions for teacher support and change in Moscow.

By now we were starting to get from you all some consensus and some conclusions. We were hearing of the need for teachers to become involved more in the change process that goes along with the introduction of NITs - and here I will interrupt myself. The Bureau of this Congress agreed that we should stop using this term and start saying Information and Communication Technologies (ICT). This proposal was too late for inclusion in the Declaration and Recommendation Document you have been given, but you will find it incorporated in the corrected version of the document which will be circulated in the final report.

Back to your gathering consensus on Tuesday. Other things which were reported from all commission meetings included the observation of the changing role of the teacher and the ESSENTIAL need to give her/him training and support as near to the classroom as possible. Of course if *Ivan Stanchev's* widely supported proposal gets established and the government of Member States take heed of our encouragement in the Recommendations to urge the telephone companies, Internet providers etc. to do special deals for educational institutions like giving us everything free, we would have an option for support right along side the teacher with all the advantages of an economy of scale that providing a worldwide service brings. In the afternoon we had another pair of superb presentations introducing the Technology theme. From *Jean-Pierre Arnaud's* speech I took particularly to his stress of the teacher's pivotal position in the learning process, and his warnings that this should not in any way be allowed to become subservient to the technology - important though this is.

Rockley Miller delivered my revenge to the interpreting system. My enjoyment of Professor Arnaud's talk was marred from time to time by loud cross-talk in Russian coming on my headset on the English channel. I fear that the interpreters had a very rough time trying to keep up with the flow of Rockley's delivery. But his content and argument was stimulating and his prognosis for the future was nothing if not optimistic. I have heard him speak several times and he always does an excellent job on his brief. Many keep up with his views and his vision through his publications. The examples of the technologies talked about in the commissions showed not only the diversity of the media but also the trend to their convergence. There was quite a bit of talk about cost versus educational gain and you will find in the recommendations two suggestions for research which might just help to pin down the role of ICT in the learning process. One not only asks for an investigation of the medical effects of technology use but also looking into its role in affecting student behaviour: the other looks at comparisons in the learning gain between traditional pedagogy, technology enhanced pedagogy and technology based pedagogy.

The International Working Party gave us a Congress based on a deliberate choice and order of themes. We started on Wednesday morning with «Social, Economic and Cultural Issues». By now we were getting to know each other and it was perhaps easier for us all to be honest in our discussions without taking or giving offence. *Dr. Poelchau* talked about all three (Social, Economic and Cultural Issues) and his concerns especially about the dominating forces of, especially, the US in, especially, the media of entertainment were echoed in several of the Commission sessions later. He also made many references back to our Main Working document, which I was grateful for, as we were beginning to forget it at this stage of the Congress - and it reminds me at this stage of my report, to exhort you to re-read that Main Document, especially alongside your reading of the Draft Congress recommendations which we will be taking next on our agenda. Following Dr. *Poelchau* we had a presentation which brought those of us from comparatively developed countries down with a bump to reality. You could not but be impressed by Dr. *Motsoaledi's* enthusiastic commitment against such enormous odds and his vigor at attacking such comparatively insuperable problems. The Northern Province of South Africa should be in our thoughts when we next complain about inadequate funding in our institutions. He tells me that he is concerned more with getting expert help to his Province even than he is with money. He doesn't want the flying visit of a so-called expert but the commitment of suitable people for at least a year to help him break through his enormous legacy of neglect and under achievement left him by the Bantu Education Act in particular and by Arpatheid in general. We had a recommendation almost at once that would, no doubt, help his Province as well as other developing countries. You will find it under Theme 6 (4).

The Plenaries on Wednesday afternoon were from Professors *Valente* and *Plomp.* The first presentation, from *Jose Valente,* gave us a paradigm based on Piagetian philosophy and argued for a constructivism through programming to a result in student comprehension, rather than the usual paradigm of the computer delivering tutorials, games and multimedia (the computer serving learning rather than teaching). Professor *Plomp* talked of the need for policy makers to be provided with the necessary information on which to make decisions and showed us some of the international statistics from his research findings in the early 1990s, and of his developing researches - a worldwide information and communication technology in education study (ICT-2000) which will look for emergent practices including in out-of-school use and the measurement of the effect of technology on achievement and attitude.

By Wednesday evening we were being inundated with excellent proposals - enough to spend UNESCO's entire budget for years to come. The Congress was in full swing. Increasingly we were hearing of the need for practice to be shared, of results and strategies to be recorded. We were reminded of the spectacular tools that ICT can provide for children (and adults) with special needs - an area which perhaps we did not cover sufficiently in the formal part of the Congress - and an area where perhaps there is best evidence for technology producing benefits cost effectively.

And so we came to our last theme, yesterday (it already seems a long time ago) in which in the Plenary we had three speakers. I thought I was familiar with UNESCO's work but I learned that I was not when I listened to the Assistant Director General with an unpronounceable name (Mr. *H. Yushkiavitshus)* who told us about UNESCO's work in communication, information and informatics. You will, of course, have his paper in the final report and it is as well as I could not possibly allow myself to select from all he had to tell us in the minute of time I have left. Professor *Trindade* from ICDE gave us an excellent overview of trends in Distance Education - another idea whose time has truly come if we are going to be able to report any progress by the next Congress. Our last plenary speaker in the last of our themes was *Wim Jansen* from the European Commission with far too much information to give us for the time we left him - and a man about to get bombarded with e-mails if the queue to talk to him that didn't get to him after his speech is anything to go by.

I will not attempt to draw from this afternoon's presentations as they are, no doubt still ringing in your ears and you have had an oral report of the workshops and of the commissions. It only remains for me to introduce the Draft Declaration and Recommendations Document and then to hand you back to the President to take you through the formal process of adopting them as the views of this Congress.

The original Is presented in English

ADDRESS

Colin N. Power

ASSISTANT DIRECTOR-GENERAL
FOR EDUCATION,
UNESCO

Mr. President,
Mr. Rector,
Vice-Presidents,
Rapporteurs,
Distinguished Participants,

First, allow me on behalf of UNESCO's Director-General, Mr. Federico Mayor, and of the Congress, as well as of myself, to convey our sincere congratulations to President B. Yeltsin for his impressive victory in the elections. At the same time may I take this opportunity to say that I am very pleased to continue to work with respected colleagues such as Professors Kinelev, Meskov, Tkachenko, Bolotov, Zhukov and others at the Russian National Commission for UNESCO.

We have discussed, in the last five days, during 8 plenary sessions, 18 sessions of the three Commissions, as well as 12 workshops, the use of Information and

Communication Technologies (ICTs) in education, in the light of the presentations made by over 100 speakers to 800 registered participants. In addition, we have had a splendid exhibition of the state-of-the-art application of ICTs in education and a rich menu of workshops. All these have together contributed to an active informed interaction and sharing among participants, which is characteristic of this Congress.

The Congress has now approved a Declaration and made Recommendations which clearly reflect the awareness that these rapidly advancing ICTs constitute a real challenge to the world community in general, and to education, in particular. I can assure you that the Secretariat will make grammatical and translation corrections as promised, before publication and distribution. I would like to stress that I was impressed by the very concrete suggestions made with respect to each of the themes chosen for the Congress - learners; teachers; technologies; social, economic and cultural issues; policies; and international co-operation. In response to the many needs and problems identified the role of international co-operation becomes particularly accentuated. You have asked us particularly to promote the exchange of successful policies, strategies, teacher education models, case studies and research, to promote networking of institutions in ICTs, to establish fora via Internet, to promote quality in the application of ICTs.

To this effect, I would like to invite you, as representatives of your Organizations and as experts in your personal capacity, to co-operate with UNESCO in the implementation of the recommendations you have just made. After all, you produce these policies, programmes and materials. We need the high level of expertise and depth of experience worldwide reflected here. UNESCO is you; it was created to represent teachers and those who work in the information and communication sciences, to promote the exchange of ideas, knowledge, programme and expertise. And you have produced many proposals for action - A Global Network for Teletraining for Teachers, a UNESCO Institute on Educational Policy and ICTs, the Workshop Recommendations.

You may rest assured that your recommendations will, in the forthcoming years, serve as important guidelines for the development of UNESCO's programme in the field of education and information and communication technologies, including capacity-building on ICTs, which is of particular concern to the Sector of Communication, Information and Informatics, and to application of information and communication technologies in education, for which the Education Sector and thus I are responsible. I assure you that the publication will be produced quickly.

One word of realism, UNESCO is an intergovernmental organization, therefore priorities among programme activities are determined in the end by the decisions of 185 Member States at the General Conference. Our budget and staff are small, so that we cannot cope with all recommendations; our role is catalytic, to ensure that the recommendations, the ideas of experts, are taken into account and influence policy. Nonetheless, I am pleased to inform you that there will be an immediate follow-up to your recommendations, and I will certainly present them next week to the Director-General together with the recommendations on the 45th session of the International Conference on Education, which will be held in Geneva on 30 September. There will be a special Round Table on the recommendations of the Moscow Congress, which will examine ways and means for their implementation.

The Director-General has also decided to inform and consult the Member States on the proposals and suggestions of the Congress, as well as on UNESCO's programme "Learning without Frontiers", by convening a meeting with the Permanent Delegates in Paris at the beginning of November, 1996. The meeting will focus on how ICTs can break down and not create frontiers and barriers - especially barriers of distance and cultural types. It has to promote the application of informatics and communication technologies in education -only to the extent to which it enables us to improve access to information and educational programmes to those who have not been reached; only to the extent that it helps us to improve the quality, the relevance and the effectiveness of teaching; only to the extent that it improves both teachers and learners.

Needless to say, the recommendations will also constitute an important contribution to the preparation of UNESCO's programme and budget for the forthcoming biennium, 1998-1999. The fact that your recommendations will guide the Organization in this field to the beginning of the 21st Century gives indeed a special meaning to this Congress and to its work.

Personally, I would like to express my thanks to the host country, the Russian Federation, to the rector of the Moscow State University and to his staff and students for their wonderful co-operation in the preparation of the Congress (hospitality, translation, interpretation, etc.).

I would like to address special thanks to the Russian Organizing Committee, led by Professors Kinelev and Meskov, and their team of 23 top personalities. One should admit that it was not easy to organize a congress of this magnitude and complexity during the week of Presidential elections.

Also special thanks are due to the International Programme Committee members, especially to Academician Y. Ershov and Professor J. Moonen, the co-chairmen, for the very rich programme created for us.

I thank also the Bureaux: Presidents, Vice-Presidents and Rapporteurs for their wonderful work.

Last but not least, I thank everyone in the conference room, all participants in this very important international event.

Thank you for your attention.

The original is presented in English

ADDRESS

V.A. Sadovnichy

RECTOR OF LOMONOSOV MOSCOW
STATE UNIVERSITY (RUSSIA)

Mr. President,
Ladies and Gentlemen,
Esteemed Colleagues,

Our Congress, I am convinced, has been successful. For the past five days we have either been participants in or witnesses to extremely interesting discussions on a whole range of issues relating to informatics and education, and have seen effective demonstrations of the possibilities of the new technologies.

While only a few years ago the big news in information technology was the introduction of computers into everyday life, today's Congress has been held against the background of the expanding possibilities in education, science and culture afforded by global network technologies, and first and foremost the Internet. This is hardly surprising. A decisive factor in the worldwide development of science and education today is the trend towards globalization and internationalization. The most significant research projects in the fields of space, information technology, ecology, biotechnology or nuclear physics today involve scientific institutes all over the world. The presentation and operational exchange of results, and the manipulation of data as usually presented in the relevant fields are now urgent tasks, the solution of which will determine to a large extent the speed of scientific and technological progress.

Allow me to touch very briefly on a number of issues which have been the subject of lively discussions at this Congress. These issues are of concern not only to me as the Rector of Moscow University. As President of the Union of the University Rectors of Russia, I know that they are also of concern to the rectors of other universities and institutions of higher education in Russia.

One of the most basic issues of higher education is that of ensuring a close link between science and scientific endeavour in the noblest sense of the word and the teaching process: a close link. between a sound knowledge of mathematics, physics and other basic disciplines and practical work on concrete problems at the cutting edge of science, using the most up-to-date equipment and technologies - this is the ideal towards which we should be striving. It is one of the main tasks of any university, but it is not a simple matter to undertake successfully.

On the one hand, in such institutions of higher education as Moscow University we have outstanding scientific departments headed by the leading scientists of Russia. These institutions are thus great reservoirs of the very best science.

On the other hand, these scientific departments are experiencing great difficulty in ensuring decent working conditions and renovating their scientific and computing equipment in these times of economic transition.

It is clear that unless it manages to do this, Moscow University will lose its leading position as a major centre of science and education. Therefore, we need to draw up priorities, one of which must be the most rapidly growing technologies in the world, information technology in general, and in particular the network technologies used by the Internet.

The global Internet network, and the information technologies used by the Internet are playing an increasing role in education. As you know, there are a number of technologies for distance education, based on specialized satellite networks, telephone channels, etc. However, none of these systems has a universal range comparable with that of the Internet in its present state. The Internet is particularly well suited to the internationalization of education. Certain countries are well known for the teaching of particular subjects. For instance, Russia has long been famous for its schools of mathematics. Using the Internet, it should be possible for Western colleagues to learn mathematics from leading Russian professors, and for our students to study physics at Stanford or Berkeley.

Such a system of universal education over the Internet would be mutually beneficial, and would help people to get the best from each country. Such a system should constitute the next great step towards the achievement of an open society. The large-scale daily exchange of information should help to make the progress of information technology in all countries irreversible, and to promote humanitarian values rather than ideological dogma.

In order to do this successfully there is a need for a well-developed Internet infrastructure both in Russia and all over the world. Sensing that the basis for the development of the information technologies of the future would be computer telecommunications, in the early 1990s we established, with the scientific equipment of Moscow University, a powerful teleport. Using the highest point of the main building of the University, we established a Radio-Relay Centre which today links Moscow University with the main scientific research and teaching centres of the Moscow region. We are participating actively in the construction of the Moscow high-speed fibre-optic highway, and are now in a position to exchange information with other leading scientific centres in Moscow. By laying the foundations of the Russian universities' computer network RUNNET, we have provided access to the global Internet not only to institutions of higher education, but also to schools and scientific and cultural organizations in various parts of Russia.

Moscow University does not confine itself to the solution of its own problems, but plays an active leading role in the community at large. With its own international Internet channels, which currently have a total capacity of 1.5 megabits per second, Moscow University is the largest provider of network services in Russia.

Three years ago we began building a high-speed network infrastructure on the Moscow University campus, linking separate buildings with fibre-optic cables. There were fears that there might be little demand for these services, and that lecturers and professors might not feel at home with the new set-up But reality surpassed all expectations, and all apprehensions were laid to rest. Familiarization with the network technologies is proceeding so rapidly (indeed exponentially) that we barely have time to help those who, for various reasons, are lagging behind (essentially those working in the humanities); we are too busy trying to satisfy the demands of those who have already acquired basic Internet skills and are eager to progress further.

There are plans for a complete overhaul of the Moscow University intranet using the latest standards for data transmission.

Today, Moscow University is able to provide all types of Internet services, from e-mail to audio- and video-conferencing. I hope that many of you participants in this Congress now realize this. All the plenary meetings, including today's, have been broadcast as video conferences over the Internet. We have also held live video sessions with colleagues from the Russian Universities of Novosibirsk and Voronezh. Indeed, over the past year we have held video conferences on a regular basis with our colleagues from Novosibirsk University and the Urals University.

Active use has been made of Web technology, and in particular there have been demonstrations of electronic textbooks in a network environment. At Moscow University, over 100 electronic textbooks and teaching aids have been created and are now in use. Many of these were demonstrated at exhibitions held during the Congress.

Given the current financial situation, these achievements would not have been possible without the support of the Russian. Ministry of Science, the Committee on Higher Education, and Russian and foreign (in particular French and German) scientific funds. Considerable assistance has been provided by commercial firms, such as Silicon Graphics. It seems to me that all possible support should be provided by UNESCO and other international organizations to science-education and academic computer networks forming part of the Internet system. Without such support, we will not be able to keep pace with the current demand. There is a need to concentrate funding on support for major national and international projects for the creation, of information superhighways.

An important issue discussed at this Congress is the introduction of the new technologies into the teaching process in schools. Many of today's school pupils will be the students of tomorrow. Hence the skills they bring with them to university will determine their ability to adapt to a new environment and to uncover their own potential. For this reason, we do not only visit schools and seek out young talent from the most remote corners of Russia and the former republics of the Soviet Union, we also help schools in Moscow to lay the technical foundations for the introduction of new teaching technologies. Today more than ten Moscow schools work over Moscow University's computer network.

In our work with school pupils, correspondence courses have proved very useful. We have several thousand pupils studying with us through correspondence courses. Using new equipment and network technologies, such correspondence courses have been transformed into a state-of-the-art form of distance education.

Over the years, Moscow University has acquired a considerable reputation for its facilities for postgraduate studies, requalification, and in-service training of university-level teachers and researchers working at the cutting edge of various scientific disciplines, in which a significant role is played by self-education, and which are particularly well-suited to the use of the new information technologies. We are seeking ways to introduce these technologies, and for this purpose we are endeavouring to establish sound technical and methodological foundations, which will thus determine the future shape of continuing education at Moscow University.

I am convinced that CD-ROM technology constitutes a promising trend in education. CD-ROMs provide a rational 'packaging' for a tremendous volume of audio and video information, but also make it possible to combine such information with an intellectual component, which is extremely important for the creation of teaching aids with assessment modules. We have just begun work in this area, and you have been able to see the first results in the form of the guide to Moscow University on display in the hall outside this room and in the exhibition building.

Dear colleagues,

We are well aware that the path leading to the solution of the problems raised and discussed by this Congress will not be easy. We at Moscow University and in Russia are only at the beginning of this path. However, in my view, the main thing is to be aware of the tasks ahead of us. to choose the right directions for their solution and to take action.

We are happy to have been able to help you and to have provided conditions enabling your work to be fruitful. We trust that you will take home with you fond memories of Moscow University, and we hope to see you here again. I wish you every success.

Thank you for your attention.

EDUCATIONAL POLICIES and NEW TECHNOLOGIES

PROCEEDINGS
OF THE SECOND INTERNATIONAL
CONGRESS

VOLUME IV

REPORTS' THESES

UNESCO INSTITUTE
FOR INFORMATION TECHNOLOGIES
IN EDUCATION

PREFACE

TO THE 4th VOLUME OF THE PROCEEDINGS OF THE SECOND UNESCO INTERNATIONAL CONGRESS «EDUCATION AND INFORMATICS»

EDUCATIONAL POLICIES and NEW TECHNOLOGIES

We call attention of specialists and all interested persons to this volume of the Proceedings of the 2nd UNESCO International Congress "Education and Informatics" held in Moscow in July 1-5, 1996.

The volume consists of two parts. The *first part* contains communications and abstracts of papers and appearances submitted to the UNESCO Secretariat and to the Russian Organizing Committee and subjected to expertise for correspondence to the goals, tasks, and topics of the Congress. These materials were sent by the authors at the suggestion of the Congress organizers together with applications for participation in the Congress. The major part of communications and abstracts was presented by specialists from Russia, and a comparatively small portion was submitted by foreign participants in the English and French languages.

Some authors presented these materials in the course of discussions at the meetings of three Commissions provided by the order of the Congress work. The remaining participants took part in the work of 12 workshops.

The topics of workshops were as follows:

- **Information Superhighways and Education;**
- **The Psychological-Pedagogical Impact and the Medical Consequences of the Application of Modern Information and Communication Technologies;**
- **The Software Environment - A Perspective for Effective Involvement;**
- **Transfer of Knowledge and Skills through Information Communication Technologies;**
- **National Policy - Transfer of Technologies;**
- **Individual Distance Training;**
- **Analysis of UNESCO/IFIP Documents published in 1994-1995 (Part I: Informatics for Secondary Education - A Curriculum for Schools; Part II: A Modular Curriculum in Computer Science);**
- **Logics, Informatics and Education;**
- **Information Technologies and Humanities Education;**
- **Development of Pre-University Education via Modern Information Technologies and Methods;**
- **Medicine: Mew Approaches to Knowledge Acquisition and Improvement;**
- **Forming Integrated World Data Bases Knowledge about Planets of the Solar System and Their Use in Research and Education.**

Since the workshops also constituted part of the Congress, *the second part* of this volume contained materials of all 12 workshops: working programs and results in the form of recommendations and suggestions.

The 4th volume, like other volumes of this series, is being published in three official languages of the Congress - Russian, English, and French.

The arrangement of materials in the first part of this volume was made by experts and editors on the basis of recommendations worked out by the Congress. In particular, the materials of the volume are distributed over different themes in the order recommended by the Congress:

- **Theme 1: Learners**
- **Theme 2: Teachers**
- **Theme 3: Technologies**
- **Theme 4: Social, Economic and Cultural Issues**
- **Theme 5: Educational Policies**
- **Theme 6: International Co-operation**

Along with this, certain difficulties has emerged in the arrangement of texts of communications and abstracts of papers relating to the first two topics, because in most materials these themes are considered in interrelation. Thus, the editors decided to join the materials of these two sections into a single section.

This volume also includes as a separate section communications and abstracts presented by the participants of the workshops «Logics, informatics and education» organized within the framework of the Congress. In view of specifics of the topic itself, these materials could not be distributed over different themes, which explains the introduction of this special section into the volume.

We decided to arrange communications and abstracts in alphabetic order according to the first letter of the first author's name.

When preparing this volume for publication, a great diversity of approaches to the problems under consideration seems to be quite natural in view of the extent of these problems. The diversity of approaches manifested itself, in particular, in using different (including new) terms which can be explained by inadequate elaboration of conceptual formalism in such a comparatively novel discipline as informatics. Not only approaches and terms were different, but also the style of materials presentation. In some papers and abstracts the ideas were put forward and defended which seem to be disputable from the experts' and editors' point of view and cannot possibly be accepted by our readers. This problem was settled, however, by pertaining, where possible, original ideas and texts of communications and abstracts. At the same time, most of the Congress materials called for editorial correction which helped us to provide the proper level of publications.

The editors will be grateful to authors and readers for corrections and suggestions. Your references will help to continue the discussion started at the Congress and unify terminology and concepts used in this field.

Analysis, selection, and preparation to the issue of this volume were carried out by the UNESCO Institute for Information Technologies in Education and by the International System Research Centre for Higher Education and Science (affiliated to UNESCO). References, notices and suggestions from our readers will be accepted with thanks by the Editorial Board.

They should be sent to the Center's address:

HUMANITARIZATION OF THE DISTANCE EDUCATION FOR DISABLED CHILDREN WHOSE MENTALITY IS UNDAMAGED: SCIENTIFIC, PEDAGOGICAL, SOCIAL AND CULTURAL EXPERIMENT

L. M. Abramson (Russia)

A project, corresponding to the title of this paper, is being implemented now on the line of the «Cultural Initiative» International Foundation. The project focuses on current problems of education of disabled children with undamaged mentality. These problems became especially crucial due to the total comprehensive school crisis, and they are conditioned by the following circumstances:

- legally established curriculum of «at home» training does not depend upon individual abilities of a child and requires 6-11 hours of training a week, but even these hours are not financed directly and/or in full, and the final knowledge potential of a disabled child amounts to 15-20 per cent, rarely - 30 per cent, of the state educational standard;
- the advanced educational institutions, as a rule, eliminate disabled children, while teachers of conventional secondary schools do not have either sufficient knowledge on mental defects and physical handicaps in children, or, sometimes, just an experience.

In addition, there is no appropriate system of training teachers, methodologists, and, what is especially important, parents so that they would be able to deal with disabled children; the scientific research and educational activities in this field have been practically completely cut down.

The lack of any prospects for full-value education, and, therefore, for professional carrier and growth, increases the cultural deprivation and isolation of children with physical disabilities. It aggravates their medical and psychological problems, that are complex enough without it, and does not leave any hope for increase in marginal status of families having disabled children (for example, the average per-person income in such a family does not exceed 20-25 per cent of the standard one; there are 1.5 times more incomplete families among those who have handicapped children; only 15 to 20 per cent of such children are given an opportunity to have the annual vacation with the purpose of bringing them into a healthier state; and 5 to 10 per cent of them are provided with interactive or/and specialised communication and training means).

In the developed countries the practice of organization of education for disabled children leans for support on significantly greater financial and intellectual resources and humanitarian social and cultural traditions. Children with disabilities study either at special schools giving them an opportunity to obtain the education relevant to their cognitive potential or, together with healthy children, at comprehensive schools properly equipped and staffed with well-trained personnel. However, our reality is far from that of the developed countries and their experience can serve only as a methodological and value-defining guiding line.

The direct import of foreign practices is also impossible in the sphere of distance education. The above form of education is widely used abroad in the field of higher education, advanced training of specialists, and continuous adult education. In Russia it cannot be reproduced exactly due to methodologically and technically limited interaction (student-tutor communications take about 10 per cent of all training time). In addition, distance education for disabled children is not very popular abroad since the needs of such children are meet with conventional educational technologies.

A model is proposed of poli-modal interactive distance education for disabled children with the use computer audio- and video-conferencing facilities. The objective of the above model is humanitarization of «individual-machine» interface on the account of: increase in time spent for student-tutor dialogue to 30 - 50 per cent, systematic telecommunication and periodical internal psychological and pedagogical support of the educational process (including work of psychologists with families having disabled members), adaptation of curriculum and training methods to an individual psychological and physiological and cognitive status of each child and his/her family and their cultural and educational orientation, compensation of informational deprivation and social and cultural isolation of disabled children trough the use of telemetric (including global ones) technologies and pertinent informational resources; and attracting of well-trained specialists to working with disabled children.

The experiment suggests an «out-institutional» character of the educational process to be run simultaneously with mandatory classes at a comprehensive school and within the limits of the permissible load agreed on by doctors and psychologists. The experiment is expected to make a serious contribution into the process of solving of numerous problems inherent to disabled children education, which are as follows:

- breaking of social and psychological and cultural isolation of the disabled children,
- creation, developing, and maintaining of modern cognitive and creative value-targeted orientation,
- developing of self-education methods,
- mastering of the modern style of information transfer in purpose of learning all required basic disciplines, or in extending/expending knowledge obtained at a comprehensive school, or in training for continuing the education (obtaining further specialised or general education), or in acquiring specific professional skills.

The choice of the information transfer mode depends upon children's wishes and/or abilities.

In the course of the experiment it is planned to test the semiotic approach to designing individual educational strategies and building the structure of curriculum contents within the framework of a so-called concept of artificial language (information-search thesaurus). The project offers the outlines of the basic curriculum and pattern educational strategies developed in accordance with the ideology in question.

The experiment involves 15 handicapped children of different age, psychological and social and cultural status and takes 6 years (37 stages). Provided with successful completion, the experiment is expected to result in establishment of an educational (network) institution that is intended for disabled children.

All the project participants are supposed to work on a voluntary basis; the funds allocated by the «Cultural Initiative» Foundation are used exclusively for purchase, assemblage, operations and insurance of technical means, communication channels, and software products required for organisation of distance education.

At the initial (experimental) stages of the project implementation the formal basis for attracting specialists (tutors) is the Article 48 of the Russian Federation Law «About Educations stipulating non-license character of the unpaid pedagogical activities.

All the day-to-day work on the project is being performed by the Family and Pedagogical Council of the Association of Parents of Disabled Children and supported by the Department for Social and Cultural Programmes of the «Filyovsky Park» Moscow Municipal District». The project progress is supervised by the «Cultural Initiative» International Foundation and the Prefecture of the West Administrative District of Moscow.

COMPUTER RESEARCH IN THE SCHOOL COURSE OF ALGEBRA AND FUNDAMENTALS OF ANALYSIS

Yu. A. Belyi, T.V. Tikhonova, G.V. Khodyakova (Ukraine)

The main objective of the school algebra course and fundamentals of analysis is the study of functions and their properties in the course of students' research work. That goal, however, was difficult to attain for a number of reasons that did not depend on the teachers (lack of time, lack of research skills in students, absence of necessary research tools).

The use of a computer is the most effective way for the solution of a number of the problems as follows:

- implementation of activity approach;
- development in the students of information and organisation skills;
- wide use of the research method.

To carry out computer studies, the students need some special software, i.e., simulating and instrumental programmes. They enable the students to manage computer models.

The present-day computer facilities make it possible for the student to examine on the display a model reflecting some features of the real object or a process. Repeated changes in the initial data and observations of the model help to obtain some useful information about the object under study or develop recommendations of the optimal parameters for the process concerned. The study provides the greatest possible intensity of cognition since the cognitive activities of the students involves practical application of knowledge that was obtained earlier or in the course of the study itself.

The students can develop research skills during the study of the material on functions in the following subjects:

- Basic properties of the functions under study (recapitulation).
- Trigonometric functions, their properties and graphs.

- The concept of continuum and its application in solving in equations by the interval method.
- Tangent to a function graph.
- Applications of the derivative.
- Application of the integral.
- Exponential function.
- Derivative of exponential function. e number.
- Logarithmic function.
- Power function.

In the course of the study the computer is both an instrument for the research process and a mean for the management of the students' activity. This involves the use of computer models that are controlled by the computer, the user not being involved; and the models managed by the user. In the former case the model is demonstrative object which is used as a mobile colour illustration of some phenomenon or a process. In the course of algebra and the fundamentals of analysis the need is great for such illustrations since the basic concepts of mathematical analysis as function, function limit, derivative and others are highly abstract. To prevent formalism in the study of the basic notions, appropriate illustrations to each of the concepts concerned are desirable.

The process of familiarization with the derivative concept involves consideration of two problems: geometrical and physical. This permits interpretation of the derivative notion from different viewpoints to promote a more profound and stable insight into this concept.

The study work by students in the above situations also involves the research methods of observation, comparison and deduction.

Let us illustrate the organisation of student research using computer models in the case when the students themselves manage the models.

Example 1. The trigonometric function graph can be considered as a model of a respective harmonic oscillation with its own parameters: amplitude, frequency, initial oscillation stage. Using the simulation programme *Graphs of Functions of the Type y = A cos(wx+b),* the students can carry out their independent research into the parameters of trigonometric functions. In this case they select one of the above functions on their own, set specific values of the parameter and observe the function graph changing depending on the parameter values.

In contrast to the conventional method of the study of trigonometric functions the models used by the students render them researchers rather than passive observers. The considerable saving of time, the quality and number of the shown illustrations are decisive in the selection of learning methods.

Example 2. In the case, when the students cannot find anti-derivative of a function in the anti-derivative table, the calculation of its integral can be performed by summing up the squares of the rectangles into which the respective curvilinear trapezium is divided. A «manual» calculation proves too laborious, and, hence, is not used at school in calculating integrals.

Let us consider the managed model which permits calculating integrals, including non-table ones, with different accuracy. The students are suggested setting the function and integration limits. Let us assume they set: $y = \ln x$, $a = 2$, $b = 3$. Thus, the problem of integral calculation could be solved.

Subsequently, the students set the number of decomposition of the segment n, e.g., $n = 4$. Subsequently, the computer monitor shows decomposition of a curvilinear trapezium into rectangles. The next stage of work is completing the table of function values. Moving the cursor along the graph and writing out the ordinate value of the marked point displayed on the screen, the students complete the table and then calculate the sum total of the areas of the rectangles displayed.

In case of great n values, the picture can be enlarged to make it more distinct. By calculating the values at different n values it can be inferred that the sum total of the rectangle areas approximates the one of the curvilinear trapezium.

Example 3. The construction of a tangent to the given point and obtaining the angular correction of the tangent is auxiliary in solving numerous problems in the course of mathematical analysis, including function study. The computer model implemented by the respective programme is instrumental in the solution to this problem. After the programme is loaded, the students state the objective of the study. The objective is only a transformed question contained in the statement of the problem, i.e. to study the relationship between the position of the secant and the value of the above angular correction.

Assume there is a certain curve on the display and a point *A* on it. One can choose on this curve another point *A1* and draw a straight line through points *A* and *A1*. This straight line is referred to as secant. Let us approximate the point *A1* to the point *A*. The position of the secant *AA1* would vary, but with approximation of *A1* to *A* it would stabilise. The limit position of the secant *AA1* in case of the point *A1* tending to the point A would be tangent to the curve in the point *A*.

Upon work with the computer model an inference is stated. Subsequently, the student translates into the language of the formulas the considered process of limit transition.

The use of computer models in the stady permits developing research skill in the students: formulation of the study problem, puttung forward a proposal, a hypothesis, and making a generalising conclusion and a deduction.

Thus the computer makes it possible a wide application of a research method in the study, which in its turn ensures productive or creative level of the study and research by students.

PROBLEMS OF INFORMATION CULTURE GENERATION

Yu. S. Bortsov (Russia)

In connection with objective processes under current circumstances the function of education has been changing fundamentally, resulting in a necessary of hands-on professional training. A school non-readiness for fast transformation brings about the loss of interest to traditional education and the school training degradation.

The educational system should be started from new principals. A school ought to teach how to conceive how to obtain knowledge independently, how to solve various problems. To master the bulk of knowledge means, above all, to master the methods and ways of data obtaining and data processing for the solution of professional problems and tasks through utilisation of information technologies. As a result, except changes in trend and methods, the cognitive content revises, also, and the training text becomes more and more reflexive. The new information technologies yield a logistic basis for solving those problems.

From this point of view one can represent the mathematics informatics (computer science) as a way of algorithmic thinking formation. By the operation of one or other software, programming languages, it should be possible to pose the goal of algorithmisation of the cognitive process itself. An algorithm laid the groundwork of one or other program all long bears both the meaningful and reflexive aspects.

It is pertinent to note that the study of informatics and the establishment of the simplest programs are also based on knowledge reflexivity, since the way of program structuring is reflection of one or other operations of a reflective character. The use of modelling, the introduction of one or other parameters into modelling and into study of a modelled object means the reflexive level of educational material delivery. Under these conditions the cognitive process is not a simple retrieval of definite system of knowledge but a mastering of ways, methods, techniques and the order of its assimilation. Works at various databases and information systems of various levels aids this. The systems of this kind permit a learner to state (formulate), to put questions, to direct and perceive a way of information search.

In order to have more fruitful view at the problems of new information technologies, their social and cultural sense and status, it is necessary to produce the extended, promising perception of informatics as informational culture. The comprehension of this concept arises along with training of modern specialists in the field of informatics. The information culture is considered within a context of common representation of information as a basis for various processes involved both in nature and society, in alter of values orientation, in systems of legal, cultural and moral norms. The necessity of informatics study in school follows from this estimation.

An important point here is that the information culture can be treated not as a peculiar system originated from a framework of new information technologies application. The first consideration here is to take a second look at information culture in interaction with other modes of culture and, therefore, in integrity of indivisible modern culture.

A phenomenon of information culture is conventionally regarded parallel with other phenomena of modern culture. Similar considerations can be applied to the fact that the same problems are generated in the field of information culture as in other modes of culture do, namely, ecological, economic and social. From our point of view it is of value not merely dwell on these evidences, but to investigate their essential basis. The case at hand concerns about the formation, for example, of ecological culture found with training of information culture and vice versa.

In this case, when viewing the information culture, we imply its capability for elaboration by means of new information technologies the various models associated, first of all, with modelling of different kinds of ecological processes. The methodical view at the world means that any purely technological problem cannot be solved without their social, economic, political, ecological background. In the frames of informatics appreciated here as the information culture it is conceivable to reproduce the given situations in a way of models laid as a basis for training.

Basically, the ecological culture cannot be fostered by means of ordinary traditional school tools. The experiences of friendly relations with environment and ecological charge of future professional activity can be formed only on the basis of implementation of accumulated knowledge. Those experiences can be arisen within ecology and informatics joining through ecological modelling. At this point informatics acts as the information culture and enables to create an universal model of world and to reproduce the actual situations which can arise as a result of one or other technological innovations.

Hence, it follows that the information culture is a new way of thinking which, however, cannot be formed within the frames of informatics training only. In that event we again come to a conclusion that critical threshold of new information technologies application in training appears not because of their deficiency in educational process or emerge of new more modern computers or computer systems. This threshold is concerned about the utilisation of new information technologies within the framework of other training disciplines and other professional subject areas. Here the priority feature is that the processes are associated with a systematic vision of the world. Being important for a politician, manager in social and political relation the above feature is completely important for a specialist in technical sphere, since the social and ecological transformations are performed as a result of his technical solutions.

It is worth noting that the development of information culture influences significantly on the nature and the extent of application of new information technologies in social life as a whole. This technological component of information culture is associated, for instance, with a creation of «information space itself».

It may be deduced that the creation of a new information culture is, from one part, the main objective of the educational process as a whole, and, form the other part, the new information culture, based upon new information technologies of training, is a necessary condition for current economics development on the basis of «non-material» intellectual capital.

The Russian Scientific-Methodological Centre for New Information Technologies in the Teaching of the Humanities and Social and Political Sciences (Rostov-on-Don)

NEW PARADIGM OF EDUCATION IN NETWORKED INFORMATION ENVIRONMENT: LEARNING FROM THE INTERNET - CONTRIBUTING TO THE INTERNET

Yu.V. Demchenko (Ukraine)

ABSTRACT

Society's demand on professional educational in modem Networking Information Technologies, mainly caused by rapidly developing Internet in Ukraine, initiated this pioneer work in Kiev Polytechnic Institute at CAD Department on developing original educational course and Instructional Methodology for teaching Computer Networking and Internet Information Technologies. Some interesting results of pilot implementation of mentioned courses and existing problems are discussed in the paper.

It was impossible to duplicate experience of some western universities in our environment with bad connectivity and poor information resources. New approach had to be found. We should learn from the Internet and contribute to building of our Internet and Information Infrastructure and Resources.

But in our local condition we couldn't teach the Internet technologies only. First of all, we have to equip future specialists with the basic knowledge in Computer Networking - how to build corporate and/or departmental network, and after that - how to implement integrated information services on the base of Internet Technologies.

1. PROFESSIONAL EDUCATION IN NETWORKING INFORMATION TECHNOLOGIES AS A DEMAND OF EMERGING GLOBAL INFORMATION SOCIETY

The emerging Information Society is characterized by wide use of modem computer communications technologies providing access to a variety of different information resources distributed over the global networks. Recent summit of the Group of Seven (G7) - group of senior government ministers from Canada, France, Germany, Italy, Japan, United Kingdom and United States - in Brussels in February 1995 have adopted plans for creating basic set of rules for Global Information Infrastructure (Gil) that will play key role in developing Global/Open Information Society (OIS) defined at the summit as knowledge based society [1,2,3], G7 declared their intention to welcome participation of developing and technology emerging countries in building Gil and developing it's information contents to provide them "the chance to fully participate in this process as it will open opportunities for them to leapfrog stages of technology development and to stimulate social and economic development" [3].

An important role in participation of Ukraine in GII development and creating elements of Open Information Society will belong to Universities' Academic and Research community. The knowledge-based economy demands greater openness and creativity in schools and universities and the acquisition of new skills and adaptability through life-long training. An open approach to education that combines local and national cultures and promotes mutual understanding between all people is required. Access must therefore be tackled at its roots by providing citizens with the tools to learn in an information society [3].

Successful implementation of Gil elements in Ukraine and its future sustainability requires a special concern about professional Networking Information Technologies Education and concurrent Training and User Support activity, which will contribute to the solving problem of preparing workforce/specialists for socially important area of academic, industry and business activity in the country.

Currently main and most notable activities in Ukraine are oriented on building regional networking infrastructure for Academic and Research communities in the frame of numerous state and international projects. Further development of Networking and Information Infrastructure in Ukraine will demand professional education of specialists in Networking and

Communication Technologies and wide User Training and Support.

Discussed project on development of Educational course and Instructional Methodology for Teaching Computer Networking and Internet Information Technologies was started by Computer Aided Design Department at Kiev Polytechnic Institute because of existing demands of Internet and Networking Information Technologies development in Ukraine. The project is based on effective utilization of existing professional resources and specialists in modern networking technologies and Internet in Kiev Polytechnic Institute that has experienced Campus and regional network building as well as in Internet training courses and materials development.

The realization of the project will help to disseminate widely and better use professional experience and knowledge among the most active layer of future Academic and Research network users which are tutors, researchers, students and associated users groups from scientific community.

The project has two parts of activities: professional education in modern Networking and Information Technologies, and associated with it training on Internet and services applications for different categories of users. This approach reflects existing in the world experience of two directions in wide implementation of new technologies: *professional education* that creates and strengthens sustainable basis (academic and research) for implementation of new technologies, and short term *training* and continuous professional renewal for satisfying urgent demands in dissemination of new technologies among wide group of users.

2. PILOT EDUCATIONAL PROGRAM ON NETWORKING INFORMATION TECHNOLOGIES AND SERVICES

Pilot group of 50 engineer students of the fifth year have started education from September 1995 till May 1996, part of them will continue their Master education till March 1997 and will work on their Master degree thesis on Internet and Networking Information Technologies related topics. Also, they will be engaged into development of complete educational course on technical and information base.

Complete Information Technologies implementation demands good knowledge and technical base in computer networking technologies. So, considering the local conditions with bad connectivity and low awarance in modem networking technologies among students and practical specialists, as well as previous educational background of students in computing and networking, a pilot course was compounded of three basic parts: Computer Networking, Internetworking and Internet Information Services, - completing necessary educational base for designing corporate and/or campus computer information networks.

The pilot educational program includes the main specialized courses on Networking Information Technologies and Information Resource Management that can be developed on existing information and technical base with minimum additional funding, such as:

- Information and Advanced Communication Technologies, society and organization;
- Computer Networks Basics. LAN and WAN Technologies;
- Internet working and Network Management;
- Internet Information Technologies and Services;
- Internet information resources development and management.

The pilot development of mentioned courses is intended to span the main issues of teaching Networking Information Technologies. Another purpose of such pilot work is to adopt and test Russian terminology on real lecturing and educational project development.

Some practical experience is acquired by students during practical projects designing in autumn and spring semesters that include development of real networks projects for concrete academic and educational institutions including development of necessary information services for operational needs of given organizations and/or user's groups. Also practical installation of services and pilot information resource development was performed on special educational laboratory base.

The projects should be developed by groups of three or four students and include all necessary components of real networking project design of campus or company's network including:

- Real conditions investigation;
- Defining user's groups in organizations and their information resource needs;
- Network structure design;
- Choice of Hardware, Software and Communication and Internet Service Providers for project realization on comparative basis among companies and providers available in the region;
- Information (Internet) server design and pilot services installation;
- Creation of devoted to the project WWW server information structure and its pilot implementation.

The methodological approach and course management system were intended to be based on students independent work and choice of topics of their educational course and diploma projects, including organizing optimal cooperative work of the project group.

The methodological and instructional materials for such project work are based on materials of real networking projects of KPI Campus Network, ISF Telecommunication Project for Creating Pilot IP Network in Kiev *(http://cad. polytech.kiev.ua/ projects/ projects. Html)* and other materials.

Initially, the proposed list of Internet services to be developed in the frame of the projects included all basic Internet services. But later, during the current projects design, it was realized that the main emphasis should be done on WWW technology. Now all projects have their temporal presentations at educational WWW server at CAD Department *(http://cad. polytech.kiev.ua/ academic/ nitsprj. html)*. Some HTML templates developed in such projects were used for completing departmental WWW Server. Many good ideas were developed by students. All were involved in information resources creation. Five graduate students have defended their diploma projects devoted to Internet and related topics that have summarized their diploma practice. One of the real results of such diploma practice was creating WWW Homepage of Ukrainian GalaRadio FM100 Broadcasting Company at *http://www.cs.kiev.ua/home/gala/* that serve information needs and listeners' auditorium feedback.

Four Bachelor's diploma works are devoted to development of components of KPI Campus Wide Information System (CWIS), Ukrainian WWW resources index database and graphics presentation in WWW. All projects will use extended possibilities of HTML 3.0 and JavaScripts. The future Master thesis of pilot group of students will deal with the very modern Internet information technologies and tools including C++, VRML, Java and shell programming for WWW and distributed applications.

3. CURRENT RESULTS AND ACQUIRED EXPERIENCE

The main intermediate results of pilot project realization can be stated as follows:

1. Creation of initial base of learning materials on Russian language on pilot courses;
2. Developing training materials for practical studying of Internet technologies;
3. Involvement of students in creation of educational base and learning projects examples as well as pilot testing of instructional methodology;
4. Creation and operation of educational server and development of students account management policy;
5. Acquiring necessary technical information about networking hardware and software as well as other information resources.

To provide efficient tool for testing students knowledge and feedback for course revising and improvement, special examination test system was developed. The questionnaires consist of 50 questions (randomly chosen and sorted) covering all key items of the course. Officially adopted, such test system could be used for specialists certification for organizational staff education and training management needs.

One of the interesting secondary result in teaching such course, mainly based on English language manuals and handbooks materials, is in rising aspiration of students to learn and enhance their knowledge of English. All educational project's Homepages have their presentations in English and Russian/Ukrainian languages, but some documents have only their original presentation in one language.

The obligatory condition for all students in these pioneer courses and diploma projects was the use of Russian or Ukrainian languages for preparing textual materials for projects. Such approach will help to create information data base for future course development and dissemination.

Another task of preparation stage of the whole project realization is to encourage the wide use of Internet and computer communications among professors, tutors and students as a way to develop collaborative learning models at the department. Professional academic contacts have to be established for cooperative development of the new educational courses and technologies at the University, in Ukraine and over the world.

To provide courses with current technical information and training technologies, professors and tutors of CAD Department actively participate in organizing workshops, conferences and seminars in Kiev and Ukraine with projects' promotion purposes (look at related events at *http://cad.polytech.kiev.ua/events/).* Participation in training activities helps universities tutors to understand better real needs of different categories of users and practical workers.

Basic training materials and courses on Internet related issues are being developed during realization of the pilot academic curricula. Also, regular training courses for different categories of users have started at CAD Department. The first group trained, surely, consisted of teacher's staff of the Department that encouraged them to use networking tools in academic process. Another one was a group of 30 students of KPI having been taken part in the international distance educational course of IUAP (International Association of Universities Presidents) on the book «Preparing to the 21st Century» by Paul Kennedy.

The main background conditions of successful realisation of this initiative activity are the following:

- leading position of CAD department in KPI in networking IT implementation;
- tight cooperation with Computer Communication Center of KPI;
- participation of specialists of CAD Department in real networking projects development and realisation;
- experience in conducting wide promotional and training activity on Internet technologies.

Leading specialists in networking technologies from local companies and institutions in Kiev are invited to read some lectures on their professional skills. Course is supported permanently by group of experts and consultants from cooperating organizations and companies.

The current experience allows to suppose that wide implementation of such course and whole realization of it's potentiality in present conditions will affect teaching of another IT related courses at the Department and their integration on the base of Internet networking and information technologies which was found to be very effective for such purposes.

4. EXISTING PROBLEMS

Current project realization was faced by number of problems caused by technical, organizational, methodological and funding reasons. Some of them can be discussed in greater detail.

1. *Technical problems including:*

- Low speed of existing Internet links that demands special buffering and mirroring of the main popular information resources (for example, RFC, Documents on Internet Protocols, Network Security, HTML and HTML Editors, weather server and pop-music) on educational server to avoid unnecessary traffic via very slow external link of Campus network;
- absent of special equipment for traffic separation of different segments of departmental LAN and efficient students' account access management.

2. *Methodological problems that include:*

- first of all, lack of experience of teaching such modern courses in Ukraine and FSU;
- absence of instructional materials and handbooks on Russian or Ukrainian languages;
- a small number of tutors with practical experience that can cover all items of prospective curriculum.

3. *Funding problems* including shortage and lack of necessary funding for proper implementation of such educational project.

5. SUMMARY

Intending for wide dissemination of current work, special Educational and Training Materials server integrated into POLYTECH Campus network was established at CAD Department (to be merged in the near future to the name *eduserv.polytech.kiev.ua)* that consists of basic information about academic curricula and students projects as well as basic training packages for training Internet related issues. Developed examination tests will be converted to interactive WWW form for providing interactive Internet training.

Necessary component of any implementation strategy will include stage of promotion to reach wide awareness of prospective users from academic and research communities with real possibilities of Internet and Networking Information Technologies, and multimedia in different areas of activity. Also, such promotion must be oriented on establishing cooperation and finding technical and financial support for realization of the full project.

We hope that such pioneer work will create base for wide implementation of Networking IT in University's environment and mobilise community's intellectual forces for self-supporting development of the new technologies. Some areas of fruitful international cooperation should be found in applications development areas, first of all, exchanging of the educational courses and instructional methodologies on different subjects interesting for foreign Universities and Companies.

PROJECT METHOD AS A BASIS FOR INFORMATIZATION OF SCHOOL EDUCATION

A.A. Fedoseev (Russia)

Computer equipment for informatics classrooms have been supplied to schools since 1985. Every such school needs to employ an informatics teacher. As informatics teachers had not been trained on a large scale, a most natural and practicable way was to retrain programmer engineers. In addition, instruction was based on learning one of the programming languages, Basic as a rule. This situation still persists in many schools despite a great number of educational programmes for individual subjects of other disciplines and those specially designed for the universal use of the computer as a tool, i.e. text and graphic editors, desk-top publishers, electronic tables and data bases. Even the transition from 8-bit to latest 16-bit computers only slightly affected their preference for Basic.

A typical situation in our school is the only teacher who knows how to use the computer is the informatics teacher. All computers are placed in the computer classroom and, consequently, can be used exclusively at informatics lessons. Moreover, the class is divided in two groups because of the limited number of computers, from 10 to 15. If a school acquires software for teaching other disciplines, such lessons may be occasionally held in the computer classroom, naturally, with direct participation of the informatics teacher as the only teacher who is able to start the programme.

Consequently, the more than ten-year-long massive introduction of computers in secondary schools did not bring about the expected informatization of instruction. The reasons are obvious now. Student workplaces are arranged basically in the form of a computer classroom. Computers are used primarily in teaching basic informatics and computer technology. As a result, *computers are used primarily for learning how to use them.* The informatization of instruction by means of computers is virtually confined in the computer classroom and limited by one discipline. Neither teachers nor educational software suppliers cannot offer the students any kind of regular and meaningful work with the computer at least in several disciplines in addition to basic informatics. Apparently, the classroom-lesson model of computer-aided learning has reached its limit. Therefore other solutions should be found to the task of further informatization of the teaching process.

One such solution may be based on other organisational models of the students' interaction with information technologies in the process of learning. Before discussing this method we should make a list of methods of the student's interaction with the computer in the process of learning and see whether they can be used in various organizational models. We shall describe the following models of using information technologies as applied to computers.

1. *The learning model.* The purpose of this model is learning and mastering the computer, a user interface and a programme. This means learning how to use a tool, or an instrument of labour. The model

presupposes the student's direct communication with the computer in order to make consecutive actions and check if the software gives adequate response. The model also has an auxiliary purpose as an introductory phase ensuring realization of other computer use models. In the majority of cases this model is applied in school instruction.

2. *The existence model.* In recent years software actualising certain artificial environments by means of the simulation method or by creating virtual reality have acquired growing significance. Multimedia facilities are also used. The user of such software, a student in our case, perceives this artificial environment as reality in which he/she for some time exists. The purpose of such software may vary. In most cases this model is realized in computer games and training programmes. The existence model is very important as it most strongly influences the user. The model is realized through direct communication between the user and the computer. Most suitable for instruction are constructive games implementing macroeconomic and social models (e.g., *SimCity, MotorCity, Civilization).*

3. *The user information management model.* This model is implemented when working with the computer the user accumulates certain information which needs special attention in terms of its storage, updating, etc. This is an independent kind of work which requires personal memory -resources. The simplest version of the user information management model is implemented by the students when they generate their own sub-directories to include the results of their work: texts, graphics, tables, etc.

4. *The technological process control model.* This model of computer use is intellectual interface between a controlled process and the operator. With regard to the learning process this model can be used in computer-aided control of physical and chemical experiments. Certain procedures for physical characteristics control in the classroom, for instance, temperature, humidity, light intensity, etc., have been developed, which can be included in the process of teaching such disciplines as physics, geography and natural history.

5. *The creativity model.* A student with sufficient computer skills, who knows how to use it as a tool (in the learning model), can be put into a creativity situation. The computer largely facilitates writing essays, making generated text designs of high printing quality. Generating computer drawings and programming can also be treated as creativity. The creative process demands a special creative atmosphere which can hardly be achieved during a lesson, and even less so in a situation when all students are expected to do one and the same thing.

6. *The communication model.* Modern computer networks perform a function of transmitting messages among their users. The possibilities they offer made them a meaningful element of human culture which cannot be realised by other means of remote message transmission (the post, telephone, telegraph or fax). Computer networks enable the users, in addition to communicating at the everyday level, to implement educational projects which contain both material for learning and certain elements of students' motivation. Furthermore, these means make remote education services possible with the help of a virtual classroom metaphor.

7. *The browsing (surfing) model.* The student with perfect computer skills usually does not start learning another kind of computer by fulfilling a task put to him/her but looking through the contents of its memory. He/she would review the directories, run programmes and look through the files which he/she finds interesting. This browsing or look-up operation is a rudiment example of actions which can be applied to Internet. It can be compared to leafing through books on a library shelf. This model is realised both to satisfy one's curiosity and as a method of information search. And it does not matter whether the person who makes the search knows what exactly one tries to find. At the moment, no experience has been accumulated of practical use of the browsing model for learning purposes. However interest in this possibility is very strong, so we may expect that methods of its use will soon be developed.

8. *The information extracting model.* This model is described here as a separate method of interacting with the computer because it makes use of other kinds of software for purposeful information search than those in the case of the browsing model. The model can be actualised when CD-ROM encyclopaedia and guides are used for learning purposes, for instance, to write an essay or a report.

9. *The mediated interaction model.* Some of educational projects do not require direct communication with the computer by all participants in the project, although information obtained from the computer largely determines the learning process [1].

All models listed above can prove useful in computer-aided learning. If, however, the *methods of the students' work organization* conform to respective models used. Below we shall discuss the former in more detail.

1. The classroom-lesson model. This model presupposes computerised workplaces of all students and the teacher. It is also presumed that all computers are united into a local network and supplied with a server. Interaction with the computer during the lesson is organized in such a way that all students perform similar or identical tasks. The teacher's objective is then facilitated. The teacher formulates problems, shows how they are to be solved and supervises the process. Control over the performance of identical tasks, as well as comparison of the results, is really very simple. This organizational model would best suit a learning model which is auxiliary to all other models. The browsing model can be used in a computer class when students do not have to perform any specific tasks but are just learning how to use the browsing procedure. All other models demand individualised actions by students and, therefore, do not fit in the classroom-lesson system.

2. The project group model. This model is based on the project method well known to educators. One of the key conflicts in the modem school is a discrepancy between the educational objectives faced by the teachers and the objectives which the students want to attain. The low significance of educational objectives in the eyes of the students does not encourage their motivation and leads to a general decrease in the interest in learning and, consequently, to lower results. One of the effective methods of raising motivation is the creation of objectives which are meaningful to the student and which can be attained through assimilation of a certain amount of knowledge. In that case purely educational objectives become a means of attaining objectives artificially set to the students. It seems fairly probable that this circumstance, which is well known to educators, can be given a new impetus due to a new opportunity of using information technologies at school on the basis of computers [3]. As the teacher masters the project method he/she focuses on educational issues, on planning changes in the educational process. The use of information technologies here acquires an auxiliary role of securing the planned changes. Since project development presupposes various roles of its participants, the computer is used only occasionally, insofar as it is necessary according to the roles distributed among the students. If several (from six to eight) project groups are in one classroom it may well turn out that one or two computers would be enough for the work of all groups. In addition, each group can use the computer in a different way than the others. The task of the teacher in such a classroom is certainly more difficult. But thanks to the students' high degree of motivation, the teacher may be at least sure that everyone is working at the lesson. The assessment of each students' results also becomes more difficult, which can be avoided if the assessment procedure is defined at the project phase. Depending on the content of the project, any model of information technology application can be, apparently, actualized, perhaps with the sole exception of the learning model. The project group model can be realized in the use of single computers or even if only one computer is available at a given school. Some projects may do with no computers whatsoever in the classroom (the mediated interaction model). In that case informatized is the learning process itself, rather than an auxiliary operation of learning how to use the computer. Practical implementation of the project group model requires that teachers assimilate new knowledge and follow a special procedure. A brief outline of the educational project development method is given below.

3. *The individual action model.* This model is best suited for home computers, but single computers placed, for instance, in a school library may be used that way too. This organizational model makes it possible to actualise any of the models of information technology use, including the learning model. Both school and out-of-school hours can be used for this purpose. If students have computers at home, the emphasis may be shifted to homework.

Educational project development technique (drawing up of instruction projects) consists of several series of stages at which the project is further adjusted. In order to develop a project its objectives and tasks must be first defined, as well as the project participants and the role of information technologies. If the description of the project conception contains answers to these questions, it can be considered ready for the next stage of project development. But before a concept can be developed it must be generated first. Analysis of a situation in which the necessity or advisability of using information technology emerged can *serve as a* good foundation for generating conception of a project. Hence, the *first stage* is formulation of the problem to solve which a project is designed. The problem should be analysed in terms of actions which are planned to be changed, flows of and methods of dealing with information which supports these actions. After that an attempt is made to formulate the name or the subject-matter of the project which would reflect its essence.

The *second stage* (project conception) begins as soon as the nature of the problem is, at least roughly, defined. Then a solution must be found. This is a stage of generating ideas. When one formulates a problem one does not yet know the solution to it, otherwise it would not have been a problem but a next stage of action. If it is a problem, not only solution does not exist yet, but even a method of solving it. So, all that is known is the available situation and the need to change it in a proper way. In order to solve the task one has to think of a method of doing this. Here a certain creating act is needed which would lead to a discovery. In other words, what is needed is a conception of the problem solution. A conception is a mental bridge linking the existing circumstance with the desirable result. There can appear several such conceptions and, as a matter of fact, it is advisable to have more than one conception, so that one could select the most productive one at the subsequent stages.

The *third stage* is the purpose of the project. In the case of a project related to the introduction of information technologies to give an answer to the question: What is the purpose of the project? - means:

- to determine participants in the project, i.e. a group of people whose activity should be changed as a result of the project implementation;
- to reveal specific advantages they will get;
- to understand what load and why should be put on information technologies.

The *fourth stage* - the time, place and the participants' roles - consists in specifying the conception. The conception is reconsidered from the point of view of who, where and when will realise it. At this stage external conditions for the p-roject and conditions of its existence are defined: the time and space limits of the project and role attitudes of its participants.

The *fifth stage* - *a* project metaphor. A metaphor consists in applying a name or property of one object to another object. Prose writers use metaphors to activate the reader's thought and imagination. A metaphor is a powerful means of uniting the project time, space and the participants' roles into a single whole. Metaphor should be sought in well-known and customary kinds of activity. A good metaphor enriches the project conceptions. A good metaphor enriches the project conception and helps to reveal its unusual aspects and new facets. If a metaphor appeared and no need arises to revise the previous stages, you may be sure it is a poor metaphor.

The next series of tasks connected with project development deals with a more detailed definition of basic concepts and terms used in the project, actions of its participants, information circulated within it and methods of its organization. The key task to be solved by this series is WHAT is done by the project.

The *sixth stage* - terminology. When the conception of the project is defined, objectives and tasks specified and participants selected and it is clear why information technologies will be involved, it is the time to agree on the language of the project. Participants in the project have been selected at the preceding stages. They are to play definite roles within its framework. They handle information, deal with various objects and act in different situations. Both project participants and those who develop it must identically interpret all terms used. For this purpose a thesaurus must be generated which would be divided into sections containing lists of terms relating to objects, situations, actions and participants of the project. Each notion in the project must be given a name best suiting it, a term or a relevant explanation.

The *seventh stage, a* responsibility table, is intended for harmonising actions to be performed under the project and agents who must perform them. The responsibility table must contain as many columns as there are different agents and a column for each role played by information technologies. Each line in the table corresponds to a certain action performed under the project. In addition to its main function, i.e. correlating agents and actions performed by them, the responsibility table enables the authors to see any errors and finalise the project. The authors of the project compiled a list of actions to be performed under the project and a list of agents at the preceding stage in the absence of any criteria as regards completeness and adequacy of the lists. Since the responsibility table reflects both lists correlated with each other, any inaccuracy can be immediately revealed and corrected.

The *eighth stage - a* «supermarket chart». The use of a supermarket metaphor for structurization of an information technology introduction project is a powerful means to find really good solutions. In order to use this metaphor one has to imagine the project as a supermarket which includes, instead of small shops and cafes, premises on which actions under project are performed. A further elaboration of the metaphor may suggest certain specifics in using the premises intended for actions under the project. The actualization of a supermarket metaphor for a specific project may demand more than one main hall, additional space in the rooms intended for actions, use of information boards in the main halls, etc. A drawing depicting the structure of the project in the form of a supermarket will serve as the supermarket chart.

The *ninth stage* - a key situation in which each person constantly performs different roles. The use of the role conception enables one to feel oneself in familiar circumstances even in a new situation. At the same time, the situation itself may suggest adequate behaviour.

When a new project is developed it is advisable to design a situation in which each participant of the project would reveal him/herself. Each participant must start working with a programme feeling him/herself in a familiar situation, in which all possible and permitted actions, as well as ways of obtaining the necessary information, are well known. Generation of special recognizable and familiar situations for the project participants must, apparently, reduce the period of assimilating new methods of work and eventually raise its efficiency. The description of a situation in which each participant will find him/herself fulfilling obligations under the project will be the key situation.

If the purpose of the project consists in software generation then the «key situation» will be transformed into a «key display». The meaning of the key display concept is exactly the same as of the key situation: the user beginning to work with a programme must always find him/herself in one and the same situation (see one and the same display). All modern software is like that: a basic working display (key display) is arranged in such a way that all the necessary information is accessible and transition to any action is possible, and having performed these actions the user will again return to the key display.

The next series of tasks further specifies the project. The basic task here is - HOW it is done. The series is realized by stages of generating procedures for man/information system interaction, dialogues, functions, states and means of transition from one level of the project to another.

The *tenth stage* - a dialogue. The dialogue is interaction either of man with a programme or by men among themselves. This interaction takes place under the following circumstances (on the basis of the stages already passed):

- selection of possible actions in the main hall of the supermarket;
- passing from the main hall to other rooms and back;
- performance of actions under the project.

Dialogues must be worked out for each situation. Descriptions of dialogues between agents should name the information conveyed.

The *eleventh stage* - a state chart. The state of the project must be reflected in the project terminology and in the supermarket chart and dialogue writing. The state chart essentially serves as a detailed scheme of the project as a whole.

The *twelfth (concluding) stage* - information on the project. The last thing to be done before launching the project implementation is to write a certain document on the project: a user manual, a brief description or an instruction. The document may be of any kind, but certain points need to be highlighted in any case, these are: formalities (authors, copyright, edition, licence); introduction (the project conception, characteristics, educational aspect); description (composition, characters, states, dialogues); instructions (for the project coordinator, for the teacher of a given discipline); supplements (technical specifications, participants' qualification).

A course designed for intensive assimilation of the project method within 10 days has been developed, on the basis of methods described above, in the Institute of Informatics of the Russian Academy of Sciences. During the course teachers assimilate the necessary theoretical knowledge, get acquainted with methods of information technology use in the learning process, acquire practical skills in project development and generate their own educational project. The results of projects previously created with information technologies are demonstrated to them, which stimulates their wish to achieve similar results by implementing their own conceptions. As the teachers feel a need for special programmes they are acquainted with the potentialities of relevant tools.

Since 1992 several courses, full or reduced, have been given. These initial attempts to apply the methods discussed above demonstrated their high efficiency both in terms of assimilating the method itself and overcoming the teachers' reluctance to use information technologies. In addition, important data were gathered on the teachers' requirements for software on the basis of which relevant functional characteristics of tools were specified and the methods of creating teaching projects were expanded and further improved. It can be safely stated that an effective means of interaction between information technology specialists and teachers has been developed which provide for introduction and use of information technologies in education and reveal what kind of information technologies are required by education.

A few years ago it was out of the question that organizational models of individual and in particular project group efforts could be implemented in practice. Curricula and lesson plans had been centrally approved and standardized nation-wide. No deviations were allowed. Today favourable conditions exist for practical realization of new organizational models of computer-aided learning, namely:

1. *School autonomy.* Each school may decide on its own what kind of study programmes its teachers will use. Some schools opt for using different methods of teaching process organisation [4].

2. *Teachers' willingness.* Ever more teachers feel a need for information technologies in teaching their disciplines. In view of this, the Institute of Informatics of the Russian Academy of Sciences developed a special course for teachers' assimilation and practical application of the project method.

3. *A new role of the teacher.* The role of the teacher as information dispenser (communicating knowledge to students) is replaced with the organizational and methodological role (organization of independent extraction of knowledge by students from various sources).

4. *The economic situation.* The project group model substantially reduces the cost of informatization of the teaching process. The same is true of the individual action model.

5. *Civilized methods.* Now schools are provided with computers on the basis of sponsor investments. Further civilizing of the teaching process might consist in applying for sponsor assistance for the purpose of not just provision of schools with computers but of implementing certain educational projects. Transition to the project group method of information technology use can give the school certain advantages in the form of adequate financing.

To sum up, the main conclusion is that the classroom-lesson model of students' interaction with information technologies has been exhausted. It must be replaced with the project group and individual models. The necessary conditions for this already exist and have been listed above. The merit of the proposed models is that the teaching process can be actually informatized at a lower cost and on a more adequate level.

LIBRARY OF EDUCATION COURSES TO TRAIN USERS OF MODERN COMPUTERS

D.V. Gaychaman, S.Y. Lavreniuk, L.V. Levakhina, E.Y. Merkulov, N.V. Nikitin, A.Y. Uvarov, A.Y. Ustinkov (Russia)

The modern computer is the best tool for mastering the new information technologies (NIT). The team of programmers and pedagogues from Moscow Physical-Engineering Institute had developed about twenty training computer courses, which are intended to train students of different ages for efficient PC employment. The courses had found the application in a number of middle and higher schools, at centres of employment service, for personnel on-the-job retraining. The elaborated reference library for training courses is an important contribution to a solution of a problem of computer competence in our country.

A traditional index depicting the extent of cultural and technological country's progress is a proportion of inhabitants able to read, write and count. Presently, this list includes, by right, the portion of active population able to employ the main computer. Nowadays principal modification of basic software generations takes place. Within the next decade this process will call for mastering operating systems (of Windows or OS Macintosh type) and the test processors (of Word or WordPerfect type), as well as electronic tables (of Excel or Lotus 1-2-3 type) and databases (of Access or Paradox type) with the aim use a computer in tolerant way. The modern computer competence implies also the precise knowledge of local and global networks and of the options of computer communications.

In many respects, the computer competence is a basis to determine the extent of information technologies and technical progress evolution for a country. Russia began to move toward the informative society creation; therefore the basic knowledge shall be promptly and widely practised. There are a number of ways to solve the above problem. But it is well known that the answer to a question: «How to train the computer mastering with a minimum of expenses, quickly and effectively?» is extremely brief: «By means of modern computer».

There is no such a field of knowledge, where the application of a computer would be more rewarding, than in the sphere of new information technologies. With the purpose of realization of these capabilities, it is necessary to establish a reference library for automated training courses that can be widely implemented both for self-training and for organized training of PC users. The team of specialists from Moscow Physical-Engineering Institute initiated the investigation of this problem in the frames of specially established by the team UNIAR company [1]. Now it is one of the leading enterprises focusing its activity on the elaboration of computer training courses on the basis of the software that is much in demand. This development was included into the «Electronic textbook» programme under State Committee for High Education of the Russian Federation. Recently there were elaborated about twenty courses, which are widely used in practical work. Some of them are as follows:

Introduction to Window 3.1. The course introduces to fundamentals and options of graphic operating system that is intended for the beginners at PC work. The training system allows mastering the navigation rules and the main elements of the system. The course consists of six lessons, in one of which the operation with File dispatcher is treated in details. In the course of operation with the programme a learner can obtain necessary experience of «mouse» manipulator use through the special lesson on «mouse» operation. The programme is beyond the demands of computing facilities. It operates well under MS DOS even at a computer of PC XT type. The programme is widely accepted and recently its extension appeared. The course introduction to Windows '95» comprises the fundamentals of system construction and methods for operating with the new version of a known operating system. The course consists of six lessons, in which a large scale of options and improved operation methods for Windows '95 are systematically presented.

The «Novell NetWare» local networks course introduces to the methods of local computing networks construction and its technologies. The learners master the theoretical basis and practical skills required for operation awareness in network and for realization of separate administrator functions in local computing network. The programme is ruled by MS-DOS.

Database entry is a computer course, introducing to databases structure and to the expedients of operation with them. The course consists of six lessons and comprises the following issues: the basic terms and definitions for operations with databases (data types, data file structure, and organisation of information search in a database). By the example of DBMS dBase there are presented the problems of development of both programme visual facilities and programmes for information input. The training programme operates under the control of MS DOS.

In the last few years considerable study is given to the office systems (MS Office, Perfect Office) in the course of users training. Their appearance and wide propagation pressing an actual standard for mostly mass spheres of computer employment and increases significantly the efficiency of operation with text, graphic and various numerical data. The possibilities of these systems are practically unlimited, they set the new level of specifications to the fundamental computer training. Incorporated into the developed by UNIAR reference library, the computer courses assist any beginner to be prepared for the job in modern office.

One of the basic instruments within any modern office system is a text editor. Both recently created courses Word 7.0 «First steps» and Word 7.0 «The way to the tops provide the initial training of users of text processor which is incorporated into the «MS Office 95» set of programmes. The courses introduce to basic capabilities of processors, teach the editing expedients and text formatting, employing of styles, patterns and means for automatic operation. Much attention is given to constructing of tables and forms, inserting of illustrations, developing of macros and using of «masters». The presentation and demonstration of a new material is accompanied with practical exercises, which are accomplished in Word medium. The programme operates under the control of MS Windows.

Other mandatory instruments of the computer office are electronic tables. They are introduced through the «First steps» and «The way to top» Excel courses. The training is underway of the example of typical bookkeeper assignments. The computer courses teach in action to use a host of opportunities of the Excel system. All exercises and practical work included into the course are fulfilled directly in the medium of Excel system. The programme operates under the control of MS Windows.

The employment of DBMS results, as a rule, in the grave troubles for majority of modern computer users. The introducing course is appeared to be insufficient for operation with databases. This objective can be achieved by means of the Access 2.0 «First steps» and Access 2.0 «The way to top» training courses. These courses allow to obtain a general knowledge on databases and to be familiar with the options of the «Access 2.0» system. As a result the learners assimilate the expedients of development and employment of databases. Up to the end of the training they are able to develop the simple database for their own requirements through the Access facilities. All practical actions, executed by learner along with advancing through a course, are accomplished in the Access medium. As in the case with other training programmes concerning about a work in modern office, these programs operate under the control of MS Windows.

During «precomputer era» the mass culture of material production for addresses was comparatively not high. The development of the systems for onscreen computer graphic sets a majority of users to make a new view on the computer use. It operates in conjunction with a system of processing Power Point 4.0 for presentation, included in a set of standard means «MS Office». The learners obtain a general knowledge on the techniques for preparation of various materials and illustrations for the reports; they study how to produce high quality presentation materials for their own lectures. The required by courses exercises and practical tasks are executed in the medium of «PowerPoint 4.0». The programme operates under the control of MS Windows.

The described computer courses are successfully used:

- at centres of retraining and skill upgrading;
- at popular education and special educational instituted;
- for self-training of professional software for personal computers.

We have referred to the selected competed developments. All «UNIAR»'s elaboration are concerned about the new achievements in the sphere of computerized training and employ the unified methodical scheme:

- reveal the utilisation range of software studied;
- demonstrate the operational expedients with software studied;
- ensure the formation 'and secure the operational experiences along with actual solution of problems.

All computer courses contain the simulator of software studied, and the learners use these facilities for preparation of exercises and adaptation to practical activity. The study period of a separate computer course amounts from 8 to 14 hours, depending upon software and personal features of a learner. The availability of Sound Bluster type computer device is desirable for courses' multimedia utilization.

As for the computer training courses, developed by UNIAR, they are implemented at the centres for personnel retraining, at the middle and higher schools at the business schools and at the courses of computer competence. Developed by UNIAR computer training courses are widely implemented in educational process at a lot of popular education schools, at MOSCOW Physical-Engineering Institute and at a number of higher schools in Moscow, as well as at training centres of Saving and Central Banks of Russian Federation, and in many specialised educational, industrial and financial institutions.

Implementation of the above programmes shows that the computer training courses appeared to be the effective tool for the establishment of basic knowledge in the sphere of information technologies and magnification of computer competence in the country.

IMPLEMENTATION OF PROGRAMMING ENVIRONMENT LOGOMIRY *TO TEACH PHYSICS IN SCHOOL*

D.A. Gorbushin, K.V. Lyubimov (Russia)

The development of new information technologies (NIT) has created the opportunities for fast increase of the efficiency of the educational process at school. NIT implementation results in modifications of the style and scales of search for the new information by both a teacher and students, and, as a consequence, in alteration of new educational material presentation by the teacher. Creative character of educational task fulfilment wills certain to become the standard for educational process.

NIT creation is the process of development of new processors, of new computers and, that is very essential, of new software.

Development of Mackintosh computers, carried out in the view of educational needs, and creation of *LogoMiry* programme environment (as a tool for development of the manuals and as a means for educational projects execution by the students themselves) shall be regarded as large-scale events.

After the authors gained access to Mackintosh computer and mastered the *LogoMiry* programme environment, they could prescribe to themselves the objective as follows: to develop a set of training materials, which could serve as a computer support for the course of physics at 7 classes of the basic school. Two pedagogical software (PS), « Rectilinear uniform movement» and «Archimed Law. Floating of bodies», were included into the above the set.

«Rectilinear uniform movement» PS was developed with the purpose both to help the teacher to foster in the pupils clear knowledge on rectilinear uniform movement and to help the schoolchildren to master the process of constructing and reading the diagrams of a movement.

When coming to the 7 classes, the schoolchildren have not less than two-year experience of solving the problems on the theme «Uniform movement», that they acquired at the lessons of mathematics. It is necessary to notice, that there are some «white spots» in the experience of the schoolchildren; they did not see the demonstration of the uniform movement, did not carry out their own experiments or laboratory work, did not make measurements of physical parameters.

Though at the lessons of mathematics at the 7 classes the schoolchildren get acquainted with diagrams of the uniform movement, they do not gain sufficient experience in mastering of physical sense of segments that are plotted on co-ordinates axes (on axis of time Or and on axis of distances *Ox* or Os). Therefore the schoolchildren, as a rule, experience difficulties, having received a task to specify a trajectory of a body movement on drawing with diagram a body movement.

It is reasonable to fill the gaps in knowledge on the rectilinear uniform movement during studying of an appropriate theme in the course of physics for 7 classes.

At the development of PS «the Archimed law. Floating of bodies» our objective was to present the main contents of the theme in evident and easy for understanding form, having avoided, whenever possible, reticences, discrepancies in presentation of the theme, which pupils meet in the school manuals.

What are the barriers on the way of schoolchildren in the process of mastering the essence of the Archimed law? The pupils study conventional formulation of the Archimed law, which is not general enough. We shall note, that in the conventional formulations of the Archimed law we meet such definitions as «displaced» liquid or «immersing of a body into a liquid» which have obviously restrictive character and, at the same time, which are not necessary.

We shall explain it by the following simple example. Let us assume that there are available an aquarium of 5 litre capacity and a piece of a material with the volume of 4 cubic decimetres and with the density exceeding the density of water. We fill our aquarium with 1 litre of water and then put the piece of the material into it. This piece, certainly, displaces some water, though not the whole quantity, but only a part of it. In this case it is clear, that the volume of displaced water cannot be equal to the piece volume. At the same time the piece and the water that are in the aquarium will take the whole space inside it.

So, we can make the following conclusion: for occurrence and existence of interaction between a liquid and a body, which is completely or partially in a liquid, a history is of no importance how this body appeared in the liquid, whether it was immersed in it, or not, and whether the liquid was thus displaced or not. The fact of the presence of a body or part of it in a liquid is the only important fact. The consideration of the above circumstances promotes a more clear knowledge of the Archimed law essence by the schoolchildren.

In the course of teacher's lectures on the Archimed law we recommend to attract pupil's attention to the following moments, which are, in our opinion, essential.

The tests, in which the bodies are immersed into a liquid and displace it at immersing, certainly, help to find out Archimed force and, moreover, to establish dependence between Archimed force and «the volume of a liquid displaced by a body». But, may be, it is possible to present to the pupils more general formulation of the Archimed law where the volume V in the formula, expressing the Archimed law, is treated as the volume of a part of a body being in a liquid.

In course of physics at the 7 classes the formula of the Archimed law is traditionally established for that case, when the body has rectangular shape. However, the Archimed law retains its validity in more general cases, when the shape of the body, being in a liquid, is arbitrary. It is important to lead the pupils to the conclusion, that the importance of the Archimed force does not depend upon the shape of a body, exactly as in the case of the hydrostatic pressure that does not depend on the shape of a vessel, which contains the liquid.

In summary, two facts should be mentioned, which seems to be significant for us.

At the beginning the PS development, we assumed, that only a teacher would use each training material as a support for investigated theme presentation. But the interest paid by the schoolchildren to our training materials set us to develop specific fragments, designed for individual work of a pupil with training materials. As a result, we produced the paragraphs of «the living book» instead of the paragraphs of «the electronic textbook». That is why we think that the future of «the electronic textbooks» is «the living electronic textbooks».

It is natural, that at the completion of the work on the training materials we have found out some imperfections in our development. In the process of eliminating of the above imperfections, we have understood that it was easier and faster to write a new fragment of the programme, than to correct former variant of the programme fragment. Thus, we were convinced that *LogoMiry* became very effective and very productive tool in our hands.

THE INVESTIGATION OF VISUAL ATTENTION OF JUNIOR SCHOOLCHILDREN BY COMPUTER METHOD

L.P. Grigorieva, M.E. Bernadskaya, V.V. Svechnikov (Russia)

Attention, as a predominant way of cognitive activity realization, ensure a successful training through both the traditional methods and the new information technologies. The computer training can be successfully put into effect, if such grades of visual attention as selectivity, concentrating, stability, switching, distribution and volume would be formed by children adequately. Insufficient development of main types and grades of children's' attention brings to its disadaptation in primary classes. Inborn or acquired in early ontogenesis, the significant reduce of eyesight is followed by a deficit of visual attention.

The evolution of visual attention is coupled with a formation of experiences to reveal and to recognise the objects at various parts of space. The exact concentration of attention at one or another part of perceptual field, where the object is revealed, is the necessary condition for realization of perception. Physiologically vigorous stimuli, which a child is able to perceive should be chosen to form such experiences. The level of resolution of image features is of great importance: their brightness, colour saturation, contrast, relief and so on. At the same time it is desirable those stimuli to cause an interest and emotional reactions with children. The surprise of object presentation is an important term to attract an attention to it. The activation of attention can be reached under the change of probability of object-stimulus appearance in view field and perceptive task, when the stimulus confers a signal way, or by introducing a feedback, or in visual searching, etc. All these circumstances can be achieved by computer method as means for investigation and evolution of visual attention and perception.

The program for realization of this method was worked out by the mathematician - programmer E.Rytsareva with a view to PC of the type of IBM PC AT (EGA or VGA monitors). The method is aimed to investigation and formation of resolution concentration, switching and distribution of attention.

From a distance of 50 cm a learner is looking at the black recording circle of 10 mm diameter in the centre of display screen. Suddenly at different distances from it along horizontal, vertical or diagonal (without warning signal) in quasi-random order the geometrical figures are presenting with dosed time of exposure. The suddenness ensures the most efficient mobilization of viewing mechanism of attention. According to a preliminary instruction a learner is required to push a key as soon as an image appears at a viewing field, and to switch over a glance to it to recognize its shape and colour. The principle of feedback is realized here along with operation. If the shape and colour were determined correctly, the green circle situated in the left lower corner, flashes with 1 Hz frequency, but, if a learner makes a mistake the red circle of 20 mm diameter flashes. The learner has to distribute its attention between stimulus and return signal. At different positions of perceptive field images can appear with equal or different probabilities. The rate of stimulus detection will prevail at more probable positions, than vice verse. PC storage automatically records the digital data concerning about reaction time and a number of mistakes in recognition of shape and colour, and the mean time of reaction is also calculated. A quality analysis of mistakes carries out the teacher. The shortage of a reaction time and decrease in number of mistakes give evidence of attention quality improving.

The technique was approved in the experiments where 37 of normal eyesight and 25 of low eyesight (0.01 - 0.1 keenness of sight) children of 7-12 years old. The analysis of results revealed the significant fall of a number of mistakes in recognition of figures and reaction time shortage for a group of normal eyesight children of 9-11 years in comparison with children of 7-8 years ($p<0.05$; $p<0.01$). The discrepancies between mean values characterizing the number of mistakes in recognition and for reaction time in groups of 9-10 years and of 11-12 years are minimal and doubtful. A scatter of values for reaction time is small for groups of all ages and shows the validity of a technique.

For children with low eyesight in all age groups the growth of the number of mistakes and the reaction time, as well as a scatter of these indexes, was caused not only by violation of sensor function, but also by non-readiness of basis qualities of a view attention. When it was required field and selective sensing of target figure, children made much more mistakes of recognition than children of the same age with normal eyesight. The reaction time was twice as much the normal value. Thus for children with residual sight (0.01-0.04) and deep weak sight (0.05-0.1), which have not gone through correction background in kindergarten and went to school, the violation of sensor-perceptive process and lack of cognitive motivation for visual subjects were combined with non-readiness of features of sight attention.

In an effort to compensate the violations of sight attention and perceptive within one academic year for appropriate children a course of perceptive training was arranged in combination with physiological and physiological methods. The control test after the course and had shown a considerable drop in the number of recognition mistakes and a shortage of reaction time over nearly all stimuli applied.

The comparison of the results obtained with neuro-physiological data allowed to suggest that the deficit of sight attention for appropriate children is caused by immaturity of cerebral activation systems because of sensor deprivation. It is shown the important role of perceptive training in compensating violations of activation processes and mechanisms of sight recognition.

This study substantiates the necessity of organization for children with violation of attention and receptive the special perceptive training, involving a marked room for computer methods with promotion of cognitive motivation. The method of this work verified as a computer technique can be applied both as diagnostic test and as a correction method developing the sight attention and a receptive in their interconnections.

DIALECTICS OF CONTRASTS OF A MULTIMEDIA SYSTEM

K.Kh. Karpenkov (Russia)

Every object regardless of human will and desire can be conceived as a dialectic unity of the positive and the negative. There is no doubt that depending on certain conditions its positive or negative qualities show themselves to a different extent. Multimedia system, a result of computer technology advancement, can also be related to such objects. Much is being said and written about the multimedia systems by both specialists and dilettantes and everybody sets big hopes on multimedia.

«Multimedia» is a new word, it has not yet been included in Russian encyclopaedias and that is, probably, why it is interpreted differently. According to one interpretation multimedia is the combination of several channels of transfer of information (sound, image, sometimes - motion of real objects) from a person to a computer; it is also implied that there is a feedback allowing a person to directly influence the sequence of events in a system.

The developers of modern multimedia systems aim at the most accurate simulating of the reality and at creating a virtual world where a human being could accomplish what he/she is not able to in a real world and where he or she would play the major role.

The multimedia technologies are very instrumental for educational process. Multimedia systems allowing for delivering the required information through different channels significantly aid in mobilization of human memory, which is especially important, for instance, for learning foreign languages.

At the present time multimedia systems are at the initial stage of .introduction into the educational process. The oncoming near research work of teachers and psychologists will demonstrate the effectiveness and efficiency of using multimedia in education.

Work with a personal computer looks like a simple pressing the buttons and, though, there is enormous labour of programmers behind these plain actions, the educational process may become rather mechanical than creative. Such education provides for only descriptive and superficial knowledge about an object or a process whereas every subject requires the ability of logical and creative thinking.

The programming of functions of artificial intelligence devices demands extensive knowledge not only about management facilities, their structure and specifics but also about receptive qualities of a human being and the laws of perception of visual, acoustic and tactile images. The software controlling such devices is very sophisticated being a product of efforts of a narrow circle of high-rank specialists. The further development and update of multimedia tools including those used for educational purposes is one of the most important tasks of the present time.

Another application of multimedia is computer games, which arouse a desire to outrun and win natural to every human being. The monotonous rhythm of a multimedia game stupefies the human mind and allows for easy influencing person's sense and feelings, which is far not always done for decent purposes. This is one of the negative qualities of multimedia but, certainly, not a reason to stop their development. Reasonable and measured application of multimedia will definitely contribute in improvement of the educational process and, subsequently, in development of an individual and the entire society.

The ideas discussed above constitute one of the possible interpretations of dialectic dualism of multimedia. It is hard to deny that some of those ideas are debatable but it is the debate that gives birth to the truth.

COMPUTER MEANS FOR TEACHING IN HIGH SCHOOL AND TEACHER TRAINING

B.Kh. Krivitsky (Russia)

Last years there has appeared a lot of programme means (software) intended for utilization in the educational process in the high school. This fact is the result of great demand for training software. The programmes are intended for application of such modern informational technology achievements as moveable patterns, sound following, multimedia means and computer networks for distant training. There has been created a lot of programmes for teaching of different disciplines, mainly special programmes, which are ready to be used directly in the training process. There appeared possibility for educational programmes exchange through Internet international networks, WWW. Along with this the experience of computer educational means implementation into the training practice has revealed a lot of problems including the problems that are directly connected with didactic process and teacher's work.

Without large exaggeration one could state the prospects of training computerization and efficiency of computer means application for the teaching improvement in high school mainly depends upon teachers, on the fact, at what degree these means would be demanded by them and how skilfully and wide they would apply these means in their practice. There are several problems connected with involving of the teachers into the process of active implementation of the above means and methods. Let's consider these problems basing on the experience of work and communication with teachers from high schools of Russia and CIS countries, who study at retraining courses under Moscow State University (MSU). Here, at the Chair of pedagogics, psychology and teaching methods in high school at the Psychology department, a psychological-pedagogical cycle for teachers of all specialities is carried out.

One of the main problems is poor psychological-pedagogical training of most of high school teachers that is aggravated by general lack of development of some didactic in the high school. Actually, during last years only few works were edited on the above problematics; and, just the contrary, it cannot be said about the number of works on didactics in secondary school. At the same time, the high school didactics as well as high school pedagogics, in general, has several specific peculiarities, which has principle character. Namely, in connection with this fact in the Centre of Scientific and Pedagogical Staff Retraining under MSU by the efforts of the above-mentioned chair a psychological-pedagogical cycle of disciplines is read, including the «Computer teaching means» course.

In contemporary conditions the motivation for the use of new educational means becomes weak. The teachers work is not in any way encouraged in this field; in the best case it is accounted as «secondary» one, low prestigious, methodical. At any rate, such work is considered as less respected than scientific and research activity of the teacher. The intensification of the above-mentioned motivation ought to be carried out not only by means of introducing of various encouragement and bonuses, but also by means of stimulating steps of the management of both high schools and its chairs, by means of creating of corresponding psychological climate around this type of activities. A significant role belongs to the competency of a teacher in the field of computer engineering and training technology. In this case the improvement may be achieved not only by efforts of higher schools themselves, but also in the framework of teachers upgrading through creating active communications with the courses of psychological-pedagogical cycle in general and educational activity computerization, in particular. It seems that this might be stimulated by unrolling of scientific-research investigations on the teaching computerization, supported by State Committee for Higher Education of the Russian Federation on high school education, by other sponsor programmes and grants.

The other group of problems is connected with peculiarities of the software in the field of computer teaching technologies (CTT). In estimation of corresponding software it is necessary to start from the fact, that the teacher, doubtless, is a creative person with his own view on what and how be ought to teach in the framework of the discipline (surely, in the frames of the curriculum and course programmes). He has his own opinion on the educational course organization, used methods and means of training. Ready for use computer programmes concerning «teacher's own» discipline, as a rule, rarely correspond to individual tastes and requirement of the teacher, since they do not take into account neither individual condition of teaching in this high school with given contingent of students, nor the peculiarities of the given discipline contents. That is why there appears a problem to develop such programmes and instrumental means, with the help of which the teacher might become either designer of certain computer programmes of teaching sphere, or obtain the possibility to break into the contents of already existing programmes, adjusting them to his demands and tastes, for examples, to choose necessary tasks from data and problem banks, to change the parameters of used computer models, to have freedom of volume and succession of training type etc. In this relation a special attention ought to be attracted to the development of instrumental means and programme envelope, such as automated training systems (ATS) as well as technology of «own» computer training courses preparation.

Currently, there has been developed several programme envelopes of ATS type of various complicity and degree of perfection, such as *«Lesson», «Adonis», «Dolphin», «Rainbow», «Ackson», «Tutor»* etc. They are not concerned to expert (or intellectual) class, but a lot of achievements of modern computer technology are used in them. Most of above mentioned systems (except for *«Ackson»* and «Tutor») present the teacher absolute freedom of activities in composing of training program. The presented possibility is followed by necessary fulfilment of the following requirement: in order to fill the programme envelope by training material, e.g. to create a computer training course, the teacher ought not only to develop the content (subject) part of the course (the whole training material), but also to create detailed step-by-step scenario of the whole training process, e.g. to carry out modelling of absolutely all possible study activities of the student.

In spite of aspiration of the system designers to make easier and several attempts to automate this work, which is not typical for teachers in «non-computer» technology conditions, it, nevertheless, maintains as sophisticated and alien, non-peculiar for teachers profession activity. The other difficulty in the development of «own» computer course in the framework of programme envelope and utilization of its information possibilities, is the necessity not only to study these possibilities and to know, how to use graphics, movable patterns, to introduce formula etc. but also to learn how to create the necessary illustrations, to realise them with skills, to introduce into computer etc. This activity requires professional skills of other experts: psychologists, painters, pencil artists etc. There appear difficulties in the design of own computer educational courses (CEC) which one stipulated by the necessity to deal with non-peculiar for teacher work. A certain way out of this difficulty is presented by computer training technology developed by prof. S. I. Kuznetsov (Moscow, 125080, Volokolamskoye shosse, 11, Moscow State Academy of Food Industry, department of ITE) according to which the teacher's work is limited by the scenario creation, while the rest part is delivered to professional group didacts, painter-illustrator, pencil artist etc. (Brief data about the systems - see collection of *papers «Computer training facilities. Didactic Programming».*

Ed. Krivitsky B.Kh. «Znanie», M.:1994. See also: Brusentsov N.P., Maslov S.P., Kh. Ramil' Al'vares *«Microcomputer system of training «Tutor»*, Nauka, 1990). The drawback of such technology is not only complicity of interaction between individual experts, but also in the fact that the teacher in somehow pushed aside from direct work with the computer. The access to the developed material is somehow impeded for him, he does not feel himself any more as an owner of the developed by him course, all the corrections and additions require work with other persons. The «dynamism» in the work is loosed, the teacher stops to feel himself as an author and designer of the course. This especially reveals at the initial stages of accustoming of the teacher to the work with computer educational means, at which he often decides, whether he would introduce there means into arsenal of usable ones, or they would appear beyond the frames of his activities. Since the initial stage is so important, it deserves a special care. It's necessary to create such conditions, in which the teacher, having minimum experience and knowledge in the field of computer techniques, could be able independently, without assistance from elsewhere and participation of other persons, to create and tune his course. Approximately such conditions are provided by *«Ackson»* and *«Tutor»* systems. Namely the easiness of mentioned systems make them preferable for teacher's work at the initial stages of attaching to CTT.

If one would take into account the necessity to increase the student's motivation to work with CTT (here it's necessary to obtain maximum accessibility and freedom of activity of the student), than it would be clear the aspiration to make the program of *«Ackson»* type as playing one, however under the condition that the organisation of such game in the problem of computer, not of the teacher. The activity of the teacher concerning the creation of computer course ought not to change in any way. After obtaining of the initial experience in the development of the computer educational courses and computer training materials the teacher may be proposed the systems with higher technological possibilities, for example, one of above mentioned.

The intellectual computer systems of educational purpose deserve a special consideration. We mean such systems as «Intertutor» and «Reviewer» (see the above mentioned references). It seems that the main problem here maintains the filling of envelopes by didactical subject knowledge.

Surely, the teacher may not limit himself by the development of CTT. There are a lot of means of training process providing, where the teacher appears in the role of a user of ready for use programmes. But they must provide the opportunity of variations while selection of the material and allow at least limited break into the choice and contents of training tasks.

Apart from above mentioned, there are a lot of other problems of psychological and pedagogical type, which though require additional theoretical investigation, ought to be enlightened in the courses, which are presented at the teachers' retraining. Let's mark some of them.

The first is the problem of the training material selection. This problem may be and even ought to be «delivered to computer». At this point it's important not only to account the possibilities of CTT, but also to determine functions, which maintain and ought to maintain in the teacher's competence in the educational activities. The other problem still is the analysis of those peculiarities and negative consequences, which are stipulated by the unlimited implementation of CTT. Some of them are already solved, while others are waiting for their investigators. It's well known, for example, that too much animation with computer training not only shortens the duration of vital human contact of the student with the teacher, but also stimulated in the student to special «computer» thinking, lacking in diversity and flexibility, typical to human thinking. In care of too much animation with computer study the practice of oral student's activity shortens in a significant degree, which is in any case insufficient. The duration of interaction with other persons during preparation of joint work also shortens. At the same time the group activities is a character feature and significant peculiarity of further practical work of the experts in modern conditions. It's important also to unroll the gravity of remote consequences of training computerization in the activity of future specialists; this is the problem, which also has not yet found its investigators.

Among urgent problems one ought to mention the problem of informational work improvement which concerns CTT and investigation of its didactic peculiarities. The main programme means of educational purpose are collected currently in the Information Systems Research Institute of Russia. The research works in the field of didactic feat uses and efficiency of these means utilization are not unrolled here thanks to some circumstances. Probably, favourable media for such work may appear at the chairs where teacher's retraining on computer educational means is carried out. This would be promoted by reading of full value courses on CTT. The organization of systematic seminars with the discussion of psychological and pedagogical problems might be useful in the evaluation of CTT. As an example, one might present the seminar, organized by the department of applied mathematics of Moscow Power Institute. The seminar is diverse according to its subject-matter; it is very useful for high school teachers on physical-mathematical cycle disciplines.

It seems that the problems affected here are typical not only for Russian reality, but present more wide interest and are actual for other countries, especially in the threshold of approaching wide inculcation in practice of distance training and Interactions between high schools through Internet.

THE ROLE OF COMPUTER TECHNOLOGIES IN MODERN SPECIAL EDUCATION AND METHODOLOGY CREATING COMPUTER PROGRAMMES FOR CHILDREN WITH BREACHES IN DEVELOPMENT

O. I. Kukushkina (Russia)

The Institute of Correctional Pedagogy of the Russian Academy of Education posed a problem of computer technologies introducing into the system of special education of children with breaches in development as a methodological problem. There was comprehended and described the role of computer technology introducing in the special education system, development of professional thinking of the teacher-specialist on mental defects and physical handicaps, general development of anomalous child of school age.

Wide introducing of computer technologies into special education in Russia has started in the end of 80-th - beginning of 90-th years, much later than in other countries of the world. By this time there was already comprehended hopelessness and uselessness of the attempts to train the anomalous children in the languages of programming. The complete change in the ideas on the computer use occurred, since then it can be considered as a new learning facility. However, either in mass, or in special education the hopes were not completely justified that the implementation of this new, powerful and attractive mean would substantially influence upon the quality and results of children education.

The experience of computer technologies introducing into special education clearly shows, that the efficiency of this process depends upon the quality of computer technologies at much lesser extent as compared to the factors of psychological and pedagogical essence of the subject, of the functions prescribed to them, of the role that they play in the educational system, and of the teachers' inclination to use these technologies in the training process. The progress in the new computer (hardware) models development and implementation of higher computer technologies into education not necessarily indicates the increasing efficiency of anomalous children training.

Implementation of computer technologies into special education does not always present progressive phenomenon. In this case the computer technologies shall lean upon various productive psychological and pedagogical ideas. Entering into already formed pedagogical systems, these new media might influence these systems in various ways. For example, in computer form some offending training methods may be repeated and replicated such as not at all the best examples of tasks, methods and skills of teaching, as well as conventional, but already outdated approaches. In this case, the computer technologies note and prolong the action of the outdated approaches in attractive form, thus hindering the development of learning systems. At the same time computer technologies are able to support and replicate new progressive psychological and pedagogical approaches, thus assisting the practice of their «comprehension» and promoting the development of the educational system development.

The question concerning new means for the system development has become extremely significant due to the fact, that the time of computer technologic implementation, i.e. 90-th years, coincided with the transformation period of state system of mass and special education under the influence of social, economic, and political changes in the country. In such critical moment for the special educational system the introducing of the above-mentioned new and powerful means might play different roles: to promote either the improvement and further development of the system, or to support the existing practice.

As to the logic of the development of the national system of special education planned and constructed on the L. S. Vigotsky's concept, which concerns developing mission of social education, new computer technologies, first of all, ought to support and note modem psychological and pedagogical approaches to the developing training of handicapped children.

The methodology was developed for computer programme creation for special teaching of school age children, processing pronounced damage of development (deaf, weak-hearing, week-seeing, children with damage of speech, delay of physical development, definite degree of intellectual damage).

Computer programmes ought to present special types of pedagogical tools, which are called to fulfil the following functions:

- to make «visible» latent in traditional training problems in child development;
- to make «visible» similarity and difference in the development of children of the same form;
- to show how one might transform the allotted problems of child development into special problems of his training;
- to show how one could interrelate the «steps» in child development with the «steps» in teacher's methods;
- to draw attention to the main substantial directions of child development and corresponding tasks of training;
- to show pedagogical ways to decide the new, earlier not existing, problems of social training.

In the framework of proposed methodology there has been designed a first specialized computer media - *«The world beyond your window»* - for primary children training with pronounced damage in development (authors: O. 1. Kukushkina, T. K. Korolevskaya, E. L. Goncharova). It consists of four parts: «Times *of year», «Weather»,* «Dress *according to weather», «Stories about times of year».*

The first part - *«Times of year»* - is a pedagogical instrument to reveal the character of child's personal experience with its special needs, measures of its generalizing, systematization, word mediation. The program propose the following principle: from vital noticing experience and child's impressions, through conscious cognition activity and modelling, to systematic generalising.

The second part, *«Weather»,* presents a pedagogical instrument for revealing problems of communicative and social-emotional development of child, assisting the teacher to see, what namely the child, without special training, is often not able to express his emotional attitude to a fact, don't understand, that other has his own attitude, don't suppose, that these estimations may not necessarily coincide. The methodological followings shows, how one ought to transform the problems of social-emotional development into the problems of special training. It shows, how one might use provided by the programme exercises for forming child's emotional reflection, methods for word expression, for transformation of the emotional relations and estimations into the object of cognition process.

The third part, *«Dress according to weather»,* is a pedagogical tool for revealing in the child the skills to utilise the knowledge for everyday problem solution. The exercises of this part of the program helps the child to learn how he/she should choose the clothes using as a reference-point firstly the landscape beyond the window and entire temperature, than the weather prognosis, and, finally, time, goal of his/her voyage, supposed type of activity.

The fourth part, *«Stories about times of year»,* presents a pedagogical instrument for revealing of hidden problems of reader's development which lead to misunderstanding of text essence. It consists of three great blocs, the titles of which reflects their objectives, such as «Preparing», «Try to think».

The *«What's the problem?»* bloc is an instrument for transfer of the «latent» problem of readers development into «visible». For solution of this problem the child fulfils lot of times one and the same exercise: «What is the time of year?» He has in his disposal four corresponding answers: «Winter», «Spring», «Summer», «Autumn». The strategy is strictly followed by: only one task and a lot of texts (60). The texts are combined into libraries, which are selected according to principle: vocabulary is always easy, the grammar is also easy, but it is gradually more and more difficult to comprehend the text. Successively increases the difficulty of essential analysis of the text. Each library presents a certain type of text, a certain mode of analysis, a definite level of text comprehension difficulty. In order to understand about what season is the conversation in the first library it's quite sufficient to «see» the key sentences with the description of clear signs of different year seasons. It's a little bit more difficult to understand the texts from the second library. In these texts there are no evident and clear directions on the year season. The child would determine the time of year only if he/she would recognize in the text the signs of the «second order». It's even more difficult to comprehend what is told in the texts of the third library. The presentations about times of the year are set in latent form, while different parts of the text born hypothesises, which contradict which each other. In order to comprehend the texts from the fourth library the child ought to allocate signs of year time and to «summarize» them in brain along side with reading the text. *«Stories about times of year»* present the instrument for determination of reasons concerning misunderstanding of the text by each child, which lie in the field of the analysis skill readiness, skills of mental activity, directed to the text comprehending as a whole.

The present media contains several hundreds exercises each of which has variable (verbal and visual) forms of presentation, successive «step by step» complication, gradual system of support, that is principally significant for successful training and teaching of all kinds of children possessing deviation in their development.

«The world beyond your window» is an example of an approach to the development of special training computer media for children with deviations in their development. These media are adequate to the tasks of contemporary stage of special education system development. In the framework of this methodology in computer form there are presented specific ways of child training with special needs, necessary for his development. Namely that is why these types of programmes may be used for anomalous child training, independently of the fact whether he studies in a special or mass school. In mass school these computer technologies would help teachers to reveal the development problems, to understand the reasons of child's failure, to open to them special, roundabout ways of children training with special needs. These technologies are developed in the frames of special psychology and pedagogy.

SCENARIO APPROACH — A CONCEPTUAL AND METHODOLOGICAL UNIT OF DISTANCE EDUCATION

T. G. Leshkevitch (Russia)

> ***«From all types of brain torporing in the result of education the most fatal for genius is dogmatic method of teaching...»***
>
> *J.Bernal*

In post-industrial epoch of development and informatization when concept «Education without boundaries» becomes priority and mostly acknowledged, one can surely speak about educational system paradigm change. Complication of cognitive process makes to re-comprehend the traditional repetition-reproductive principles and supposes the appearance of «computer link». Effective method innovations of heuristic character are actively inculcated into the educational process. In the conditions when principal change of communication means is carried out and as an important component of teaching appears «computer page», contemporary progressive training technologies have a right to rely on adequate estimation and active application.

The proposed model of scenario approach includes one of the most effective mechanisms of dynamic teaching methods and presents a conceptual-method unit either distance and open or postal and stationary education type. In its base there was set a four-block algorithm, which realises during logic-methodological and psychological investigations step by step model of decision acceptation. It includes the stages as follows: informational, selective and estimation, expert and specialised (final) blocks (stages). Each stage has a fixed with it certain tasks and functions. Each block is oriented on satisfying of special cognitive demand in information, selection and evaluation, expert analysis, final generalizing and prognostics. Their combination supplements the training model up to the necessary and self-sufficient integrity. The subject of training process, mastering step by step the functions and tasks of each block, masters the methods of essential training and literate constructing of the materials.

The main goal ***of informational stage*** is maximum wide information about the problem, based not only on «book» knowledge, but also on personal experience, own representations and suppositions. In this primary information the limitation on the material selection are illuminated in order to stimulate the heuristic search, and reveal the authorised portrait of the trance. Only initial elements of structurization are maintained. The informer is proposed to comprehend the goal of his presentation, fixate certain ideas and main settings, open his own views and carry out personally important conclusions. The ways of thinking might be different, they depend upon individual tendencies of training subject appeared in the block of informers, and logic that was chosen by him. As an account form it is supposed to prepare an informational page (abstract text or base synopsis).

The task of ***selective-estimation block*** consists of selective chose and estimation of the material on the studied subject-matter, elimination of non-strict, tautological formulations and accentuation on the proper settings. Here so called «opponent principle» is used: to reveal the advantages, formulate critical remarks, to tell the proposals. The account form supposes the packages of control questions on the theme, in the list of which not only direct and leading question are allowed, but also the questions relied on the erudition, supposing multi-aspect vision of the problem (ethic, aesthetic, utilitarian, historical, economic). Apart from package of questions, the account form contains problem cards. In these cards there is supposed to present the interpretation of the chosen fragment of the original text, or to comment the possible non-standard situation. All possible formulations of creative tasks are welcomed. It's supposed, that these forms would allow to reveal the creative potential of the participant of the education process.

On the third-expert stage it's in prospect to create a scenario, in which the main accent falls on the revealing of key ideas combination, their interconnection and hierarchy. The main and additional problems are classified in it, the dominating and determining problems are defined, the system of organization is mastered. Apart from them the reason-consequent connections and temporal graduation are revealed. The scenario is considered as a hypothetical succession, which answers on the questions: how could the proposed task or problem develop step by step, what are the methods to preparation of this or that result?

In the process of scenario construction several approaches are possible. Traditional, approbated by centuries method of training in accordance with principle «Do as I do» supposes detailed following the classical narrative scheme of material delivering from easy to complicate. «Method of socratical ironic» allows moving of contents confronting the opposite position. This method contains step-by-step setting of the question, acceptation of this or that variant of answer, and again successive correction in meeting of new question. So called «*Janus thinking*» tunes of disproof of proposed decision and confirmation of alternative one. Another approach also is possible, in which from the central idea the successive position increase and develop.

The account form is the scenario of expert proposed with the account of frame law. The trainee himself proposes the graphic scheme, while its internal content ought to be strictly connected with professionally mastered material.

The final (specialized) stage is connected with the fulfillment of integrative function. Here one ought to present the result of the theme study, e.g. to fixate strict and unrolled plan of the answer or the hole study. It's possible the coexistence of alternative essential approaches. The account form - scenario of the specialists - is devoted to illustration of dominating idea, formation of the answer structure, revealing of culmination points in the content of the considered material. In this scenario one ought to outline the trajectory of the idea moving with the account of successive of bearing points: problematic standing of the question; hystorical-phylosophical, scientific, culturigical excurse; the theory of the question, prognostics, prospectives and tendencies. On this stage the trainer is supplied by special creative and managemental functions. Towards this functions is aimed the last of above mentioned positions, which foresees the way out of the limits of found and estimated information; defining of its personal significance and practical applicableness; acception of recommendations of methodological, ideological and practical character; extraction of moral aspect of the problem.

The proposed four-block algorithm is principally new method, which present «wasteless» training technology. In its use the subject of training, successively processing each of the roles and participating in the work of all blocks, is able to use the obtained skills, simultaneously reproducing of all functions in short and concentrated form. Apart from that as account forms he should present the material of selftraining, which present not only indication of material mastering level, but also may be used as a method production, as data base or patterns for further course provision.

The model also contains the elements of search investigation activity. The problem, determining the sense of each stage, becomes personal problem of the trainer in connection with the necessity of preparation of corresponding account form. This is the base for evident interest in reaching of its solution, the way and method of which is mainly dependent on subject's preferring, his erudition and intuition. The real possibilities of creative personal selfpresentation consist of the fact, that the tasks, fulfilled by the subject of the sense of their originally may overcome the algorithm of the model.

The system is early unamenable to application in the conditions of rating control. The fulfilled tasks according to the blocks are estimated by comparison with standard models, giving a unit scale of evaluation. The model overcomes the limitations of narrow specialization in the boundaries of disciplines of humanitarial profile, allows to eliminate the problem of monopoly of private narrow specialized methods. Combining the advantages of traditional approach with principal innovational generalizings, the proposed model allows to solve a set of problems:

- to inculcate the skills of system thinking and reach the completeness of the material mastering;
- to process the methods of defining of key ideas and promote appearing of linguistic freedom of the material presentation;
- to work out the graphic scheme of contents construction and maintain the right for free search of truth in the channel of considered thematic;
- to initiate personal system of argumentation, strictly fixate value-estimation metrics of the answer and professional competence.

For a long time traditionally accepted and in many cases antiquated model, so called questional-answering or repetitional-reproductive model, has fulfilled functions of unified, obligatory, educational standard. Empirically it has discredited itself from various points of view, but its drawbacks are not revealed methodologically up to now. Owing to the inertia of method thinking the main efforts are directed not on constructive reorientation and conceptual transformation of antiquated noneffective system, but on its modification and toughening of normatives, requirements, proscriptions and reglamentations. Among with this in the conditions of changing educational paradigm, based on computer technology opportunities, it becomes evident, that old model is not able to fulfil functions of unite obligatory for everybody standard.

From the point of view of contemporary methodology the main criterium, which qualities the appearance of new educational paradigm, is change of the educational process. Namely the mechanism of selforganization is indisputable method advantage of the proposed model of scenario approach. A specific significance is presented by laid in the method opportunities to create an atmosphere of stressed intellectual search, so called «brain attack», which allows to consider sophisticated theoretical questions and decide them in the context of contemporanity.

NEW PRINCIPLES IN THE DEVELOPMENT OF SPATIAL THINKING USING NEW INFORMATION TECHNOLOGIES

M. N. Maryukov (Russia)

When investigating the problems connected of the inception and development of spatial thinking we are guided by the following thesis: new information technologies determine new principles in the inception and development of spatial thinking at various levels of the learning process. School teaching comprises a major stage in this integrated process. Modern school should provide for the level of a learner's spatial thinking which would be adequate to his/her natural desire to develop as a balanced personality.

Scientific disciplines, such as physics, chemistry, biology and geography have a serious contribution to make into the attainment of this purpose. However, the priority in the development of spatial thinking has traditionally belonged to mathematics, geometry in particular. It is quite understandable considering that geometry is concerned primarily with the study of the objects of the surrounding world and their interrelationships on the basis of their mathematical models.

Russian schools place much importance on the subject of geometry. This attitude has found its reflection in the fact that, beginning with the seventh form, geometry is taught as a separate subject. However, in most of the schools in Russia and other countries where geometry is taught as a separate subject it is traditionally broken down into plane geometry (study of flat surfaces) and solid geometry (study of three-dimensional objects), with the former predominating in the schools curricula. In our opinion, it is an imposed distinction which is not at all in line with the pronounced aptitude for spatial perception of the objects in the surrounding world found in the learners within junior and teenage groups.

That is to say, the level of spatial thinking in the learners which we would like to-develop in the course of school education on the basis of new information technologies would be impossible without relinquishing the traditional system in favour of new conceptual approaches to th& school course of geometry. One of these, in our opinion, would be to compile a course in basic geometry (for 7 - 9 forms) based on the principle of full or partial fusionism, that is, approach it as an integrated course without breaking it up into a school course in plane geometry and a school course in three-dimensional geometry.

Currently, intensive research is carried out in Russia in this direction and experiments are conducted in schools to explore the implementation of the fusionism principle at various levels of the course of geometry study. The fact that the problem has attracted the attention and efforts of mathematicians, psychologists and experts in mathematical education allows to regard fusionism as one of the current trends established in school education.

When working on new principles for the application of information technologies in the educational process at school, we proceed from new approaches to the composition of a new basic course in geometry and from the fundamental goals sought by the study of mathematics at school, which are to help the learners develop:

- spatial thinking;
- conception of mathematical simulation, including its applications for the purposes of scientific research and natural exploration;
- concepts of new methods of information storage, processing and transmission.

These educational purposes have a pronounced generally human aspect, are interrelated and cannot be treated in separation. Proceeding from them, we can formulate the role of computer technologies in the study of geometry as a concise but hopefully expletive thesis: *we regard the computer as a means for studying spatial geometric objects depicted on a flat surface in the regime of learner-computer dialogue.*

Therefore, we are actually dealing with computer simulation of spatial geometric objects, allowing us to accomplish the following:

- explore variations in the model's behaviour in relation to the changing characteristics (in particular, its position in relation to the picture plane and the observer's eye);
- mark sections of the spatial image and operate with the marked sections in accordance of the set tasks;
- mark two-dimensional figures of the depicted object and examine them using the method of transition to the original;
- make geometric constructions on the depicted object in conjunction with the posed problem, and transform the image to achieve the desired figure;
- enter the results of the learner's operations in the computer's active memory and carry out their computer analysis and control.

These possibilities, combined with the principles of graphicalism and fusionism, can lead to the formulation of new principles of the development and stimulation of of spatial thinking in learners attained within the basic course in school geometry aided by the application of new information technologies. We believe that the new principles can be formulated as follows:

- identifying a class of geometric problems designed to develop and stimulate spatial thinking, which provide the basis of computer education and form a corresponding computer data base;
- development of computer means for the solution and examination of the problems;
- providing for the entry of the learners' results into the computer's active memory and development of an effective system of computer analysis and control these results;
- organising a context-oriented computer aid providing for work with several active aid windows and for monitoring the basic stages in the solution of a given problem as depicted at the changing graphic model.

These principles underlay our tutorial designed for development and stimulation of spatial thinking in the learners within a basic computer-aided geometry course. In our belief, the development of this kind of tutorial may be of immense importance, since it is the first ever case in the world practice that the significance of computer technologies for development of spatial thinking has been approached from the angle of psychological motivations, analysis of new trends in the education in geometry, examination of domestic and foreign teaching practices, and, what is especially significant, with special consideration taken of the special features characteristic of the thinking process in the learners within junior and teenage brackets, who have an "extensive practice" so to speak, of existing in the real physical space. Our psychological and methodological guidelines determine the computer's didactic functions, of which the main one is to ensure a differentiated approach to education in geometry, exercised with a view to a learner's individual aptitudes and abilities. This is intended to apply the process of learning geometry a creative and interesting activity, within the scope of practically every learner, which is in line with the current tendency for humanization of mathematical education.

These new principles of developing spatial thinking with the aid of information technologies and the tutorial system developed for the purpose require the development of corresponding teaching software. Their subsequent advisable implementation in school may, in our opinion, promote the attainment of a desired educational effect from the application of new technologies which is, so far, still ahead, as far as geometry is concerned.

To this type of software we attribute novel computer geometry-teaching aids, which have no direct analogues in the world. Their distinction from existing educational software lies in the availability of the following subsystems:

- a computer data base, compiled of the problems comprising the basis of computer-aided learning of geometry and aimed at development and stimulation of spatial thinking in the learners;
- among the major computer methods of manipulating spatial figures we list, in part, computer simulation of a figure's rotation in space and transfer of its plane elements to the original. With the help to these methods it is possible to explore the model's affine as well as metric characteristics;
- a system of computer analysis and control of the actions taken by the learners to solve a geometrical problem. This implies that, for every problem, there exists a system of expert knowledge, that is, a multitude of possible solutions of this problem, represented by a certain aggregation of data . The main function of the computer assessment and check-up system consists in generation of a multitude comprising the results produced by the learner in the course of his/her computer session and in correlation of this multitude with the given system of expert knowledge;
- a computer aid system comprising: (a) diagnostics of the errors; (b) access to a solution of

a similar problem.

The computer base comprises the following major categories of the problems resolved by manipulation of images:

1. Finding visible and hidden elements of a polyhedron, depending on its relative position to the picture plane and the observer's angle of vision; picture to picture passage.
2. Identifying the juxtaposition of points, lines and planes determined by the polyhedron's elements.
3. Constructing figures with preset properties on the polyhedron's image.
4. Analysis of the juxtaposition of two or more polyhedra and determining their intersection proceeding from their images.
5. Determining a polyhedron's configuration proceeding from its image by investigating its plane elements.
6. Constructing the polyhedron's net and investigating the polyhedron's properties using the unfolding techniques.
7. Transforming a given polyhedron into a required type by the method of image transformation.

Computer methods of solving and analysing the problems within the seven categories described above have a common foundation and only a few distinctions referring to details. These methods include:

- *construction / elimination / marking* of a point, segment, half-line, line, or face;
- computer simulation of a geometric figure's spatial rotation;
- transition to the original of the plane elements of a spatial geometric figure.

The efforts towards the creation of a a computer system of analysis and assessment of the learners actions in the solution of the problems headed under the seven categories as described above involves the creation of the mathematical basis of such a system. This basis, in our point of view, is provided by pattern recognition problems, that is, the problems of correlation (understood as comparison or matching) of two aggregates, X and Y, presented as certain data structures, whereby X is the aggregate of problem solutions and Y is the aggregate of a learners results. We believe that the data structures required to represent X and Y are those ordinarily used for depicting a graph as a computer image. Representation of a polyhedron as a graph results in the aggregates X and Y comprised of a finite number of graphs which are sub-graphs of the initial graph corresponding to the given polyhedron. In this case correlation of the aggregates X and Y is a relatively easy task leading to the creation of an effective system of computer analysis and control.

So far, our considerations pertained primarily to the new principles of developing and stimulating of spatial thinking in the learners within medium school age groups learning the basic course in geometry. The same principles, however, could be assessed and applied for to the study of geometry and relative fields at various stages of learning, including the higher education establishments. At these levels, the development of spatial thinking should be exercised with regard to the learners' professional orientation. Needless to say, there should be some differences in the level of spatial thinking developed in the profession of economist, engineer, or teacher of mathematics, etc.

New information technologies help approach the problem of professional orientation in the development of spatial thinking from a principally new level, based on the development of a system of problems underlying computer education and designed for the development of spatial thinking with regard to the future professional interests of the learners. Problems in linear and non-linear programming resolved with geometric methods are intended primarily for a future economist, for example, while a future engineer's problems are those dealing primarily with computer graphics algorithm, and so on.

We are well aware that a certain amount of knowledge in this field has already been accumulated in the world. However, the analysis of this experience from the angle of new principles of the development of spatial thinking, the analysis of existing and design of new educational software, the assessment of accumulated knowledge and development of a common educational strategy in this area can, in our opinion, become a major promising line for the UNESCO Institute for Information Technologies in Education.

PROBLEM OF ADAPTATION OF THE EDUCATIONAL PROGRAMMES TO INDIVIDUAL PECULIARITIES OF THE STUDENT TRAINED WITHIN THE FRAMEWORK OF ECOLOGICAL PARADIGM

A.S. Molchanov, V.N. Krut'ko,
A.M. Bolshakov (Russia)

The research object of forming now area of knowledge as ecological psychophysiology is studying physiology of mechanisms of physical processes as general acts of interaction with natural and social environment.

The problems of ecological psychophysiology with reference to educational process can be formulated as follows:

- specification of the mains factors of environment influencing to activity of the teachers and of the students;
- analysis psychophysiology of effects arising as reply to influence on the individual factors of environment, and effects of their cumulative influence;
- study of mechanisms determining result of

pedagogical and educational activity;
- modeling of educational process and development of the recommendations on its perfection.

The process of training is provided by set of the simultaneously influencing on man factors. They can render as repressing process of knowledge mastering, even damaging influence, and developing, enriching influence.

Important stage of modeling of educational process is to create right classification of the forms of behaviour and conditions appropriate to them forms of educational activity. However, in connection with constant change of the contents and conditions of educational process, the number of the factors loses its importance, and conventional educational technologies are changed for the new ones. (Computer training method is one of such new technologies). Such variability complicates the creation of completed classifications of the factors of educational activity, since it requires its continuous review.

Research now under way of the important factors of educational activity and results of their multiplied influence has allowed to specify the main forms of behaviour and activity of a person in educational process, but also conditions appropriate to them of training of the students in high schools and colleges. Besides there were specified representations of the students concerning the most favorable conditions of realization of the various forms of educational process.

As a condition of creation an effective system of educating is formation of the positive emotional attitude to the future professional activity, process and conditions of their purchase, and we specified emotional tone of environment types that differ in purpose. The interesting in this question is explained by increase number of cases of occurrence at students from a higher school psychosomatic infringements, necessity of founding behaviour types of algorithms in various conditions, specification of ways of decrease probability of occurrence of deviations social behaviour learning.

We had lead a series of experiments on tone study of emotional reactions, arising at youth of student's age in communication with the various forms of activity and by conditions of activity. Doing this part of research has allowed to develop criteria of differentiation and emotional estimation of the diverse forms of activity and conditions appropriate to them of professional education.

Studying of emotional tone of the various parties educational and not education activity of the students has shown, that neither of aspects this activity has no steady negative colouring.

In separate series of experiments there was shown the connection of the characteristics statistical models developing with EEG-indicators of such various on functional purpose properties HNA as force, liability, and equability [Molchanov A. S., 1989]. It gives the basis to believe, that the applied ways of representation of data can reflect steady peculiarities emotion of student.

Research of emotional tone of the various functional parts of educational process has allowed to specify conditions, which provoke chronic emotional intensity, ways of its decrease, ways of preventive maintenance of occurrence of deviations in social behaviour and psychosomatic infringements. Doing of this stage of work makes clear the way of correction work, developing in pedagogical psychology, besides permits to lower an emotional pressure and, as a consequence, the probability occurrence of early psychosomatic pathology.

Especially difficult is to model individual peculiarities of emphatic students reactions. In this connection we studied the opportunities of the formal perception processes description, of mechanisms included into the system of the emphatic reactions (identification of stimulus causing the emotion, expressing displays of the observable person and etc.) [V.N. Krut'ko et al., 1993]. These processes are making afferent link of reflection of mechanisms emphatic reactions. Besides identification of expression behaviour of the observable person there was used the opportunity of the formal mechanisms of identifications description of a context of the whole situation was investigated, which role are ambiguously by the various authors [A.A. Bodalev, V.V. Stolin, 1987].

Received results let us to assume existence of hierarchical organization considered cognitive and emotional processes, where mechanisms of emotion and the environments identification are systems of a lower level, in comparison with process of an emotional estimation of educational environment and whole educational process.

It is necessary to pay attention on similarities and distinctions between representatives of various cultures concerning perception and emotional estimation by them various types of environment. The established facts permit creation of the reliable tool of forecasting psychological effects arising as a result of an environment influence.

As the result there were established criteria for the quantitative measurement of an estimation of quality and conditions of education in high schools including material and psychology aspects. It has allowed to pass to development of a technique of an estimation of professional training conditions of the staff in higher school.

The formal description of emphatic reactions is suitable for their computer modeling and development of individual correction algorithms of functional infringements in emotional sphere.

Thus this research opens the opportunities for development and inclusion the block of an estimation individual psychology peculiarities student in trainee computer programmes and by that to raise qualitatively of teaching level. Psychology analysis of individual peculiarities of the person and behaviour of the student in educational process will allow to choose the most suitable algorithm of computer education.

On the basis of this work it is possible to include the block of research and account of individual peculiarities of cognitive and emotional student sphere in trainee programmes and it is possible to construct educational process on the basis of individual students psychological peculiarities according to these peculiarities restructures the training programme.

DIAGNOSTICS OF THE PECULIARITIES OF COGNITIVE ACTIVITY OF SCHOOL STUDENTS USING COMPUTER TECHNOLOGIES

L. I. Peresleni, L.A. Rozhkova (Russia)

To reveal the cognitive activity of children for forming classes in the system of differential teaching and also to correct developmental deviations it is necessary to use methods permitting to obtain not only qualitative but also quantitative characteristics of the levels of the development of various psychic functions, which permits their quantitative assessment. It is feasible to include in the psychodiagnostic set used for these purposes to sets of complementary techniques. One set would promote revealing of the level of development and the state of psychic functions, operations, and processes, i.e. the peculiarities of development and state of assessment and emotion-volitionary sphere, i.e., the properties of voluntary regulation of activity, which essentially determine the receipt and processing of the input information and solution to intellectual problems. The concept of the need of the use of two sets of interactive methods to assess the state of the psychic activity is based on the modern concept of physcho-neurophysiological mechanisms of higher nervous functions (Luria, 1973; Farber, 1978; Khomskaya, 1987; Peresleni, 1984; Peresleni, Rozhkova, 1990, 1993; 1995). This selection of techniques is particularly important in the examination of junior school students that approach medical and educational consultations due to problems of knowledge assimilation.

A set of complementary techniques permitting assessing the level of development and the peculiarities of different psychic functions and to reveal some neurophysiolgoical mechanisms determining them was developed.

The method for the research of prognostic activity (PA) *(Ugadaika)* advanced by L.I. Peresleni and V.L. Podobed (1982) was constructed on the basis of the findings of the studies of psychophysiological regularities of the development of probabilistic prediction. Earlier, we widely analyzed the relationship between attention, memory, perception and thinking. The importance of the investigation of these processes to reveal the specificty of intellectual development resulted in a technique to elucidate the qualitative and quantitative characteristics of predictive activity and determine information indices for the assessment of psychic properties in both normal children and those with intellectual deviations.

The revealing of the PA properties using *Ugadaika* to a larger extent than other psychodiagnostic methods permits approaching an assessment of the state of intellect in the understanding of the psychophysiological mechanism, which is constantly active, serving as a condition for the establishment of essential bonds in the relationship between the events.

The indices obtained using the proposed method permit judging of the properties of the long-term and short-term memory, thinking and such attention properties as stability and switchover capacity.

The technique uses the situation where the subject is to establish independently the sequence of alternation of two events on the basis of correctness or incorrectness of their predictions taking into account the appearance of these events in a sequence. The technique involves three sets of cards with printed letters *A* and *B* on one side. In the form of game the subjects are exposed to the cards on the display. Each letter is presented as the subject presses the key corresponding to the letter being predicted. The letter sequence patterns are set by the program and vary depending on the age of the subjects. For junior school students the following three sets are used: 1 - 20 cards with an *«ABAB...»* sequence, repeated in 10 cycles; 2 - 60 *«AABB...»* sequence cards are used, which are repeated in 15 cycles; 3-60 cards with an *«ABB...»* sequence - 20 cycles.

The computer treatment of data permits representing in text and graphic form the indices characterizing the properties of the solving of a prediction problem: (1) the number of erroneous predictions; (2) the number of errors associated with unstable attention; (3) precision of the reproduction of the perceived sequences; (4) specificity of the strategies used. The data base also contains information about the temporal parameters of the prediction process. The different characteristics of the 4 basic indices described permit distinguishing different types of cognitive activity, reflecting the properties of the development of particular psychic functions.

In order to reveal the neurophysiological mechanisms determining the properties of the cognitive activity, the psychological data are compared to the electric cortical (reaction of activation) and vegetative (skin galvanic reaction) components of the orientation reaction (OR) to the sensory stimuli of different signal significance and also to the specificity of the bioelectric activity of the brain in the state of rest. The registration, processing and analysis of electrophysiological indices are made using the hardware-software complex *Neurokartograf,* developed by the *MNB* company (Moscow).

The study of the subjects of different sex with different cognitive characteristics correlating with the success of learning or with the problems in learning of different ethiology (due to retardation of psychic development or speech retardation) has revealed an interrelationship between the behavioral characteristics of cognitive activity and the properties of the OR and the background EEG.

It has been established that subjects with normal intelligence that did well solving a prediction problem, the duration of the reaction of desynchronization of the activity of the occipital and central zone of the cortex exposed to both indifferent and relevant stimuli substantially exceeds that registered in individuals with the peculiarities of PA determined by deficiency of attention or/and memory, which indicates the insufficiency of ascending activating and corticofugal regulatory effects. The disturbance of mnemonistic functions is associated with an absence of strengthening of the reaction of activation in the central region with an increase in the significance of the stimuli, which is considered to be a manifestation of insufficiency of associative processes. The weakness of the activation reaction is also correlated with a less pronounced skin galvanic reaction, particularly when indifferent stimuli are perceived.

In case on ineffective prediction in individuals with learning problems of different ethiology of middle and senior school age, there is a paradoxal increase in the duration arousal in the projection zone of the cortex into indifferent stimuli; along with that the activation reaction to the relevant stimuli remains to be weak. In addition, the associative zone of the cortex remains to be insufficiently involved in the OR.

The different types of PA correlated not only with the OR features, but also with the characteristics of the bioelectric activity of the brain in the state of quiet wakefulness indicating the specificity of the functional state of the central nervous system. In fact, subjects with insufficient effectiveness of PA, in particular with memory disturbance revealed a weaker development of the alpha-rhythm, which is manifested in its irregularity and a low spectral magnitude. Along with that, in the cases children could not make efficient prediction, high-amplitude, hypersynchronous alpha-1 rhythm was often recorded. In the cases, when inefficient prediction resulted from retardation of psychic development of the children, a high frequency of the occurrence of EEG signs was recorded thus indicating a dysfunction of the stem structures of the brain and the immaturity of the cortical rhythmicity. Children with speech pathology, along with involvement of stem and medium structures of the brain also show focal changes in the cortical rhythmically, more frequently, in the temporal regions of the cortex.

Thus, the results of the comparison of behavioral reactions of the process of prediction with the OR features and the background EEG in different-age subjects permit a qualitative and quantitative assessment of the development of a number of psychic functions to reveal the neuro-physiological mechanisms responsible for the deviations in the intellectual development revealed.

TRAINING TECHNICAL COLLEGE TEACHERS IN ENGINEERING PEDAGOGICS

V.M. Prikhodko (Russia)

Russia with its immense scientific and pedagogical potential is one of the leading countries in the area of training workers in engineering occupations. The Russian school of higher education, based on a rich and diversified national tradition has sought to apply available achievements of modern science attained by domestic as well as foreign researchers and experts in teaching, which has earned the it a well-deserved recognition in other countries.

The changing socio-political situation in the world dictates the need for the Russian institutes of higher education and their teaching teams to try and take an adequate position in the fast-changing situation at the world market of educational services. The establishment of the Russian Monitoring Committee (RMC) for engineering pedagogics accorded the status of a national division of the International Engineering Pedagogics Group (IGIP) is designed to facilitate the attainment of this noble goal.

One of RMC's major objectives is assistance to IGIP in the compiling of the International Register of Engineering College Teachers (IGIP-Register). Entered in the Register are specialists of the qualification level and practical experience which satisfy the requirements placed by IGIP upon the teachers of engineering subjects. IGIP-Register entry automatically affords the title of the "European engineering college teacher" (ING-PAED IGIP).

The Register makes available to the potential employer the obtaining of detailed information on the educational and professional level of the registered members of the teaching profession, as well as guarantees regular confirmation of the teachers qualification by way of permanent control and check-ups designed to ensure that the members qualification corresponds to the theoretical and practical standards as worked out within the international framework.

On the whole, the enrolment of Russian members of the higher engineering teaching school in the IGIP-Register should have a favourable effect on the current trend of extending services in the training of foreign learners. The Russian teachers entered in the IGIP-Register may freely pursue their professional activities in Russia as well as abroad.

To be entered in the Register, a teacher should be able to pass certain qualification standards based on the fundamental principles as described below.

1. Sound technical knowledge is a basic requirement upon a teacher of an engineering profession. Therefore, IGIP-Register membership requires a higher technical education and experience of practical work, which corresponds to the FEANI "European Engineer" (EUR-ING) qualification. It is desirable that the engineering qualification of an applicant should be up to the EUR-ING standard. The applicants with the qualification satisfying the FEANI standard receives the titles of both "EUR-ING" and "ING-PAED IGIP" and his/her name is entered in the Registers of both these organisations (FEANI and IGIP).
2. It is equally important that the applicant should possess adequate engineering-pedagogical knowledge. The applicant's training in this area should be based on the minimum of 200 academic hours (a full higher school term). The content of the engineering-pedagogical training should incorporate the engineering-pedagogical model and the curriculum worked out by IGIP.
3. The preliminary condition for application is the minimum of one year of practical engineering-teaching work.
4. The applicants are required to have an active knowledge of at least one foreign language.

IGIP recommend that the engineering teacher-training curriculum should incorporate the following subjects (the figures in brackets indicate the minimum number of teaching hours):

- fundamentals of psychology (16);
- fundamentals of sociology (8);
- fundamentals of communication (44);
- fundamentals of compiling a technical text (16);
- fundamentals of technical training (12);
- biological fundamentals of development and training (8);
- the didactics of laboratory studies (12);
- fundamentals of engineering pedagogics (36);
- teaching practice in engineering subjects (36).

Specialized teacher-training centres for advanced and refresher courses have been set up at seven institutes of higher education under the State Committee for Higher Education of the Russian Federation for the purpose of promoting and improving the teachers qualification in the field of engineering pedagogics.

THE NEW INFORMATION TECHNOLOGIES: WHAT ARE THE POSSIBILITIES FOR HIGHER EFFICIENCY AND MORE EQUALITY IN EDUCATION ON THE VERGE OF TWENTY FIRST CENTURY?

Hamidou Nakuzon Sall (Senegal)

ABSTRACT

The systems should be profoundly reformed in order to meet the demands and challenges of the 21st century. As a matter of fact, if school takes into account the quick evolution of knowledge through the impetus of the new information technologies, it would have to set up educational strategies suitable to the cultural, scientific, technical and technological, but also economic context.

The necessary reform of the educational systems is a must for all the countries. The growing unemployment of the product of the educational systems reveals the failure of the training provided at present, to adapt all teaching levels including university. The feelings that school is worth nothing, that teaching finally takes to nowhere, can be rectified and corrected by raising the cultural and scientific level of each country through involving the parents into the education process for their children, through consideration of great variety of the social groups.

Therefore, the educational systems should explore new strategies, which will make all actors of school (students, teachers and parents) learn how to learn and learn how to undertake.

At the beginning of the third millennium, educational projects should be constructive; they should aim at more effectiveness, at more efficiency and equity. The opposition between formal and informal education should be banned.

INTRODUCTION

1996...1999. 20th century is nearly beyond us. Less than in four years we'll celebrate the end of this century and the beginning of 21st. Are we ready to meet it? Are we ready to overcome all the problems, which are looming on the horizon? Are we ready for innovations, which cannot be accomplished without modernization of the educational and training systems? Are we ready to meet challenges arising from entering of young people into active life?

Perhaps we are dealing with capability of young people to respond to a challenge of time? Perhaps we are dealing only with the ability to solve the problems to be sought by modem youth?

Let us think about the words of the President Abdou Diouf [1]: «Let us train teachers. Let us send girls to school (educated women are the basis of social progress in future). Let us. arrange the textbooks and training appliances. Let us not forget about adults, about their urge towards the study. They must not be separated from their children by a cultural barrier that, in addition, constantly grows». «To train teachers» -this could be served both as a statement and a sketch of sight. The statement in the sense that modern system of instructors training does not look completely efficient; while the sight tells about the necessity to put teachers in possession with professional tools, which could help them to be on the height of numerous problems.

The slogan «To send girls to school» might be understood as follows. The women constitute the larger part of the mankind, and this fact that shall be taken in consideration in the process of project development for higher and secondary education.

«To arrange the textbooks and training appliances» would mean the acknowledgement of outstripped training tools and, therefore, the anachronistic character of knowledge and skills, which school enables now.

«Not to forget about adults» would mean that any school project is doom to vegetation, if it ignores the training appliances, which a learner can and should obtain out of his environment, as well as, if school culture is completely drawn away from social and cultural environment.

But perhaps the abyss breaks apart only young people and adults, men and women?

As a matter of fact, the modern world is deeply marked by antagonisms, which equally interfere for flourishing of individuals and development of society. These obstacles break down also all efforts, directed to mutual understanding and tolerance within the relations between the nations, peoples and cultures. The strongest antagonisms can be presented by cultural, scientific and technological gaps between North and South, city and village, well informed groups of people and those who are not provided with sufficient information.

The education, in general, and a school, in particular, would, however, not intensify contradictions, but erase or weaken the existing distinctions and the most typical antagonisms of our era. The new information technologies present them such opportunities providing that there will be exploited all their probable or imaginable advantages.

In fact, the cultural (in a broad sense) and pedagogical innovations which the new information technologies, so to say, impose to modem educational systems, could be expressed by formula «to accommodate or to perish». To accommodate to modern life, to accommodate to practically permanent, and as if instantaneous, renewal of knowledge and skill, is a universal challenge:

1- for adults,

2- for educational systems,

3- for a society.

1. ADULTS

This conclusion is applicable all over the world. In fact, in great majority of cases the adults are, so to say, illiterates in context of the present time. They are illiterate, since they are afraid of new technologies, afraid to investigate novelty, afraid to cast doubt on their knowledge and ability. On the contrary, when we simply follow the young people mastering the modern techniques we always admire their deftness to subordinate them and to become accustomed to these new means (especially at the level of users).

Illiteracy of adults most strikingly is expressed through distinctions between nations. In countries, where a school was imposed by colonial history, one can state two factors. From one side, a school tile nowadays had not received wide acceptance, from the other side, it distributes its blessing through a language, which is often a foreign (not mother tongue). This double statement means, naturally, a serious obstacle for any effort in favour of development.

New information technologies provide almost ready for use means for abolition of the above barriers. The educational systems should be rearranged in a way that a school could take over the task of reinforcing and conducting a policy in elimination of illiteracy in national languages, the task of distribution and popularisation of scientific and technical information on the same languages owing to mass media: the press, radio, TV broadcasting. Acting so, a school could have been promoting to step up a standard of culture and science of each nation.

The new communication technologies can promote the elimination of people illiteracy since they ensure the effective neutrality, relaxing the search for the best combination between formal and non-formal education. The task - to step up a standard ofculture - also would allow to enable more fairness, fairness from the standpoint of accessibility to modern knowledge and to guarantee the terms, under which the abilities to meet one's demands would spread fairly.

Among positive consequences that could induce the step up a cultural standard of nation in the area of education and specialists training, the possibility for observation after school children teaching may be cited for parents. The step up of nation cultural standard would allow for parents to participate directly in school deals of their children. The latter would obtain the necessary pedagogical support from their parents. The direct pedagogical assistance at home would improve the school results.

The utilization of new information technologies in educational system for adults serves, therefore, as an important means for enforcement of internal efficiency of educational system. It does not seem to be a chimera to use the new technologies in the interests of the system of scientific training of adults and, by and large, to set up nation cultural standard. In fact, the use of everywhere radio and TV broadcasting would allow to elaborate programmes of remote training for a lot of people. With this in mind, the teams, including communication and remote training specialists would be entrusted to create the special programmes, to develop the appropriate strategies of those programmes evolution with estimation of their efficiency. Thus, the programmes on the basis of radio and TV networks would combine the educational tasks and analysis of their audience features. The new information technologies would also promote the enforcement of sequence extension of educational transmissions, bringing them to designated population sections. For instance, the optional programmes introducing to new technologies would promote the relaxation of social burdens in the countries, where the relations between people are of great importance in social life. The popularization of telephone communication service would be used for improving of quality and quantity of contacts between members of the same community. The telephone service would allow to spare time in this event. As a matter of fact, cheap telephone contacts would permit to shorten the family visits. In big cities, where the urban transport is an expensive pleasure from the point of view of its price a telephone would obtain the significant economy resulting in investments of spared funds into culture.

Finally, the new information technologies make it possible to reconcile the formal and non-formal education: they would supplement each other. And it would become possible to break down a crosspiece, which separates them now.

2. EDUCATIONAL SYSTEM

It seems to be trite to state that the educational system is experiencing any crisis. Schools run into crisis of «choice», supplemented by a moral wear of school programme contents. The crisis of "choice" had touched all educational systems. The more and more young people put themselves a question: what for to go to school for, if in graduation they are waited for unemployment. In reality, this crisis of "choice" reveals the lack of ties between a school and its social environment, the shortage of adequacy between knowledge and ability in school, from one side, and the professional skills and knowledge, from the other side. The impression is posed that a school trains for skills, which are failing to exist by the time when the training is completed. What could you say then about the professions, which will be required to a society in 21[st] century? Today nothing is known about the vast majority of professions from tomorrow and about their essence.

The young people, who are going to begin their business activity in 21[st] century, do not venture to be deceived by the "games" of adults and do not trust them. They realise that their future is vague. They think that at school they lose their time in vain and that they will be badly prepared for real life when they leave school. Therefore, they strive to other educational system; the adults are most commonly not ready neither to propose such systems, nor to present and to implement them.

In spite of all disappointments, induced by training, the demand for education is growing everywhere. An increasing number of parents are dreaming to send their children to school; this is their right, this is their duty. At increasing number of school the children are dreaming to prolong their education in higher school; this is their right too, and our duty is to help them, even in those cases when we do not know, for what university to prepare the children. In fact, under the combined of demography, democracy and information, and in spite of contradictions, a school remains the most important source of knowledge. A school, in representation of people, remains one of the rare chances to avoid a worse destiny. Thus, a school appears to be a place where knowledge acquired, in order to be realised as individuality, as a producer and citizen in a society.

Under the combined exposure of demographic, democratic and economic factors the estimation of efficiency of educational systems is related to evaluation of fairness extent. On the contrary, the system can burst and cause the social disturbances with unpredictable consequences.

The efficiency and fairness suppose that a school will help people from professional, social and personal point of view. Dialectics of the concepts «to be» and «to have», evolution of expectations and demands enforce the educational systems to renew permanently, in order to renew the content of training. Also, the methods of training must be renewed frequently. Didactic techniques must be revised from time to time. Besides, the tasks of education need to be revised and newly stated.

The new education becomes really encyclopaedic. The volume of knowledge, that finds no application now, constantly increases while the most essential is not separated from auxiliary.

More than ever the matter about the training methods is appeared to be in the focus of educational world, preparing the specialists. It may be of interest that methods, based on passing of the own knowledge are out of date. Certainly, and active pedagogy, based on scientific psychology (to teach pupils how to learn) are also shown evidences of some exhaustion.

As of now the new information technologies and changes, which they generate in all orbs of activity, pose the teachers confront the new problem. Because of development of technology and means of communication the information became a raw material for all areas. By means of information a man discovers the abilities that he did not suspect earlier. That's why it is necessary to develop urgently such pedagogical approaches that are able to evolve the learner's capability to absorb, accumulate, process and use the information.

The unwinding of data banks and their place in knowledge obtaining make the pedagogical methods, based on a new structure of school and even on other principles, actually required. The search of efficiency and of increased fairness, which are in the centre of school care, make it to take into account the specificity of different groups, which it accepts. They dictate to school, first of all, to evolve the pedagogy of success and to finish with pedagogy based on a selection and on defeating. Thus, there is a new paradigm: learn to study.

If a school can teach to master learning from school ages, to get accustomed, in particular, for searching an information, to analyse the available information, in order to find the most adequate and most suitable information regarding to posed aims, to master business from school ages, being accustomed with independence and, later, to arrange one's own working place and one's own company. A school then would not be forced to prepare the pupils to payable job, but it would impart an ability to be adapted to a crisis of employment.

The new instruments, which are needed for mastering, and the methods, which will allow the learner to master them, pose the other educational tasks. Among them, the priority should be granted to the aims of integration. The splitting of those instruments for a number of subjects must be conceded to formulating of subjects that enter various disciplines. The objectives to be pursued along with training process shall be, unless real situations are stimulated at least, approached to them. As a result, the goals of certification, which are so dear to recent systems, give way to fundamental knowledge or to minimum set of knowledge. But this generates the necessity of other ways and other criteria of evaluation.

In the long run, the information technologies impose to schools the way to be followed. The case in hand is, specifically, the necessity to bind a school life and survival after graduation in a better way. The better co-operation between a school and labour should be under seeking too. A school must act reciprocally with environment. At the same time a school is forced to be involved in a process of remote training and continuous process of adults' education for nation cultural standard set up. The industrial world and enterprises, being equipped with newest technologies, shall be a peculiar providing ground for pedagogical tests in real conditions. In other words, the educational systems must have intention to conclude contracts with surrounding companies, because it seems to be of low-probability and of expensive deal to equip schools in such a way, that they would be able to provide the education with true correspondence to technological standard.

The contracts signing between elements of educational system and economical infrastructure suppose synchronously, that a search in school and university medium must be in combination with taking into account the true demands of civil society. Moreover those draft- contracts will bring quietness to local communities and will allow getting the sources of self- financing in educational systems.

3. SOCIETY

The new information technologies incline the whole society to be matched to modern technological environment and, first of all, they force to observe attentively over its evolution. It should be necessary, also, to participate in technological development, trying to control it that is to manage of ruling with it.

As a matter of fact, the careful analysis testifies that world itself is now more than ever a "global village". In this sense, an interdependence of nations, now more than ever, is a reality. Social and economical and social and cultural development of each country forces it to co-operate with other world countries. The modern states shall be inevitably incorporated into sub-regional and regional unions. The general-purpose culture of mutual understanding is necessary for prosperity of each, out of lawful part of modern world.

The consequences that are presupposed by new information technologies in our modem states are noticeable at different levels as follows: philosophical, political, legal, economical, scientific, technical, technological, religious etc.

From the standpoint of pedagogy, which is our interest the new information technologies require our countries to issue a new educational philosophy that in greater extent will promote the economical and cultural integration. From this point of view, the national educational systems, closed by definition, shall make room for more open systems. "To be more open" means that the educational systems are obligatory to determine the minimum of universal knowledge and competence. And the diploma ought to be given a new definition in order to provide mobility for learners - the potential workers and instructors.

It is known, for instance, that the obstacle for development of higher education in Africa, to the South of Sahara, is often the absence of high ranked professors, summoned to deliver their lectures and to guide the researches at post graduate level. To overcome a deficit of high ranked professors, the universities at South are enforceable to call not infrequently the scientists from North. Such movements and the allowances for business trips are a heavy burden. The budget framework, that the universities can not overcome, enforce them to make scanty choice: whether to refuse from arranging of local training which standard corresponds, more or less, to third cycle, or to send students, capable to claim for training level like this, to other countries.

The use of pedagogical possibilities, presented by the new information technologies in social and economical and social and cultural medium, less binding from juridical point of view, would help to avoid the dilemma of this type. In fact, the universities would be able to use for educational tasks the possibilities of remote training, proposed to them by electronic communication.

The use of e-mail for the tasks of educational and professional training assumes a number of preliminary terms. In this aspect, the determining of tariff rates, differentiated over the customer's services, would be a subject of special investigations for the national communication services. In many cases such events are summoned to respect some administrative and lawful restrictions that restrain their technological capabilities. All main limitations bear an evidence of ideological and political character.

The timid attempts in the region of private TV broadcasting and the counteraction to leasing of vacant channels at satellites interfere to development of qualitative remote training, acceptable in connection with a price and time. However, the direct access to a satellite jointly with TV stations establishment, is a compulsory condition of remote training in harmony with technological development.

In many respects the ideological and political practices are appeared to be the major barriers for education development in many countries. It may be argued that surrounding us political culture is a main break on a way to unify the basic training. It is precisely these political traditions and behaviour, which they induce among the society strata leaders, is a real obstacle to the ascent of scientific and cultural standard. As a matter of fact, the technologies, capable to promote the establishment of quality TV- training, are mastered enough, however, the "political will", probably, not always follows in this direction.

In Africa, to the South of Sahara the universities and higher education, which are often collide with the problems of infrastructure and staff, could help to wider strata of population in each country and in groups of countries, if the powers could agree to realise less elite policy, and, therefore, more democratic policy, if they would have more broad view on sovereignty, on knowledge and education.

INFORMATICS IN SECONDARY SCHOOL AS AN APPLIED SUBJECT

Yu. A. Shafrin (Russia)

Within the framework of the school programme on informatics and computer technology the ABF Publishihg House has issued a textbook "Information Technology Basics" intended for Russian secondary schools.

There is probably no one other sphere of human activity that would be growing that vigorously and provided that variety of approaches as informatization and computerization of society does. The history of information technology development is characterised by rapid change of conceptual notions about the role of various methods, equipment, and people involved in this business. The fundamental monographs and small brochures on the subject written only 5 to 10 years ago are now despairingly obsolete. The information technologies based on huge computers equipped with displays-terminals and, as a rule, not having their own processing units have become the history, though, at that time they seemed to be very promising.

Only 3-4 years ago a slogan saying "Programming is the second literacy" implying that every educated individual has to know how to create algorithms and use programming languages such as FORTRAN, BASIC, etc. seemed indisputable. However, a powerful flow of the state-of-the-art software poured into the Russian market during last two years made for a situation when "home-made" programming became not only unnecessary but impossible. More and more people wanted to know how to use industrial software products instead of mastering classic programming.

I would like to stress that the textbook we published cannot be compared to any other one published before. The reason is not that our book is worse or better, it is just different. All the previous textbooks on computer science are the extension of a school course on mathematics implying that their readers have in-depth mathematics knowledge. Apparently, this approach is suitable only for students of specialised physics and mathematics schools, gymnasiums, and lyceums whose future professions will be directly or indirectly related to programming. However, the overwhelming majority of all school students will face a completely different problem - the total coverage of all spheres of our life by computer technology.

Unfortunately, either evidentiary programming skills or knowledge of Prolog language will be useless under this new environment consisting of files and floppy-disks, word processors and electronic tables, data bases and Windows - the fireworks of software and hardware embarrassing even for experts.

On the other hand, the authors of the textbook cannot accept a counter opinion on the problem of teaching informatics at school which suggests mechanical training on selected software products.

That is why the textbook is focused on informatics as an applied course intended for school students to understand the basic principles and capabilities of modern information technologies including principles of operations of hardware and of the most widely used software applications. Generally, the textbook is a well-structured course of modern applied informatics concentrating mainly on Microsoft technology (Windows) which actually became a generally accepted standard in Russia. The textbook describes the major principles of text and graphic user's interface and the techniques for creation of graphic images by means of Paintbrush software.

Three chapters of the textbook are devoted to the most commonly used triad of operations: word processing, operating spreadsheets, and managing data bases. This triad was not selected occasionally or according to the likes of the authors, this knowledge is demanded by today's computer technology environment. The powerful integrated applications use the same triad (e.g. Word-Excel-Access in Microsoft Office). The authors attempted to shatter the current delusion that the informatics is needed only for those who is going to deal with exact sciences or, for example, with accounting. The proficiency in information technology will be equally useful for a doctor and a lawyer, a historian and a journalist, a writer, a composer and an actor. The authors made an attempt to intelligibly explain the readers the structure and capabilities of databases, their benefits for people of various professions (focusing more on humanities than on science and technology), the techniques of databases creation and operating, etc.

The concept discussed above does not imply that the authors of the textbook undervalue the importance of developing student's algorithmic thinking. The book offers a lot of examples and problem-solving questions illustrating the main ideas and approaches, the principles of operation of a personal computer as an automaton capable only of phenomenally fast performing four basic arithmetic operations and comparing values. In addition, the textbook gives the readers an idea of what is programming. Much attention is given to general vision aspects of informatics.

It should be noted that the textbook has also some conceptual peculiarities. First, the training is supposed to be based on modem industrially produced software products instead of artificially selected "school" languages and obsolete programmes. Second, the textbook is intended for school students of senior grades, i.e. those who already have serious background.

The authors tried to avoid abstract formulas preferring to either thoroughly examine a problem or briefly explain its essence and solving techniques.

Example 1. When describing relational data bases (the basis of modern information technology) it is insufficient to discuss the simple two-dimensional tables and suggest a student making up an example on some familiar subject. The experience shows that this seemingly simple problem is full of pitfalls and difficult even for a specialist if one is not familiar with the principles of data structuring and normalization. That is why these issues are explained and analysed in details in a separate chapter of the textbook. At the same time, the authors devote significantly less time to description of data bases operation techniques relying upon practical training with a teacher.

Example 2. Boolean algebra is fairly considered to be one of the main elements of informatics. Unfortunately, it is sometimes too abstractly communicated to students and it is very difficult for one to puzzle out of those "conjunction, disjunction, and implication". We tried to explain the principles of the Boolean algebra briefly and clearly as well as to demonstrate its role in the processes of information retrieval from data bases and spreadsheets.

Example 3. When preparing a chapter under the title of "Computer in a modern society" it was planned to include a section in it containing problem-solving questions on optimal programming (considering the fact that the compact packages on this subject are available). However, the material appeared to be so extensive that we decided to omit it limiting the chapter to brief explanation of the essence of optimum choice problems.

An important element of the textbook is the glossary including generalized definitions of major terms used in applied informatics. Basically, the glossary is a brief summary of the textbook designed to assist a student to arrange and verify the information obtained. The inclusion of the glossary was determined by not only the availability of various terms and concepts (mathematics, cybernetics, etc.) but also by their different interpretations depending upon specific tasks and objectives. For instance, logic operations being discussed in two chapters of the book required a single commentary which was included in the glossary.

The textbook questions and assignments were selected in accordance with our approach to the problem and with school reality characterized by a variety of computer facilities available and by different orientation of schools. All the questions aim at developing objective-targeted and logic thinking of students, their decision making skills, etc. The practical sections of the book offer relatively small number of basic examples (pictures, texts) based on which a teacher will be able to select interesting assignments considering the capabilities of the equipment available.

Our textbook gives a teacher freedom in selecting theoretical and practical material and methods of conducting the lessons. One is free to use supplementary textbooks, books and other reference literature (the list of such literature is available at the end of the textbook).

A crucial moment of training is the strategy of conducting practical classes which are actually the key element of training. Our textbook can be used with practically any kind of equipment and software, however, the selection of specific configuration depends upon specific school, its objectives, and its financial capabilities.

There is no upper limit for equipment and software products to be used with the textbook. For example, if school computer facilities are equipped with 386, 486, and Pentium computers, the training can be based on Windows applications: Word (word processor), Excel (electronic tables), Access (databases). But even then the authors believe that it is necessary to start with studying basics including DOS and Norton Commander as these very systems allow for easy mastering filing, retrieving information, and other important skills; without knowing DOS it is hard to acquire serious information technology knowledge.

The students should master fundamental principles of information technology and learn to find their own way in the ocean of computer information to be able to solve any specific problem they face. Various reference books, textbooks, specialized periodicals both for beginners and advanced users will help them to achieve that. The major objective of our textbook is the same as of those on fundamental sciences: "Remembering facts is not that important, much more important is understanding the subject".

The above is a summary of a certain concept declared. This is for critics and teachers to assess the results of its implementation. The authors realise that there is no ideal, meeting everybody's expectations, solution for such a complex problem of teaching informatics. Other opinions and approaches are unavoidable. That is why the authors welcome any suggestions, reviews, comments, and remarks, no matter how critical or sarcastic they would.

COMPUTER AIDED ENGINEERING EDUCATION IN A CHANGING ENVIRONMENT

Ahmad R. Sharafat (Iran)

ABSTRACT

In this paper, we will discuss the use of computers in engineering education as a tool to complement the teacher. The reasons for such use and their ever increasing necessity are also presented.

INTRODUCTION

Well-trained engineers are essential in successful implementation of economic development plans. At today's pace of new technological innovations, the professional life-time of engineers is constantly shortened. As the economy expands, the shortage of up-to-date and qualified engineers is being felt increasingly. The cost of retraining new engineering graduates and the time it takes put extra pressure on universities to train the engineers more effectively, and to emphasise practical skills while preserving the fundamental concepts. Industry needs engineers who have a broad view, are flexible and have been trained in such a way to easily absorb new information and adapt to new situations [3]. In addition to retraining new graduates, we should also plan for retraining those engineers who have graduated in the past and need additional training to enable them to follow new developments in their fields. In addition to all this, we are constantly faced with requirements to retrain existing engineers who have worked in one field but are now required to undertake a different task in a different field.

The situation is more critical in developing countries, where a visible lack of established industry with well planned and effective on-the-job retraining and continuing education programmes and facilities add to, other difficulties that emanate from social and economic settings; in addition, the shortage of qualified teachers at all levels force us to consider innovative approaches such as computer aided engineering education to improve the productivity of the educational system in general, and that of institutions of higher education in particular.

We can benefit from computer aided engineering education to overcome some of the difficulties that were mentioned so far. Careful implementation of such programmes can assist us to realize desirable results. However, one should not forget that computers are tools in the same manner that text-books are. We can not replace teachers with computers for the same reason that textbooks alone can not produce well-trained engineers. Engineering education is expected to develop judgement, insight and intuition [1] as well as skills. Teacher's role as mentors and «intellectual parents» who not only transfer and propagate their knowledge but also their standards and ideals can not be undertaken by replacing them with computers. It is not clear how creativity and insight are taught. It is for these reasons that we have to emphasise the importance of teachers as irreplaceable assets in any society.

THE CHANGING ENVIRONMENT

In recent years, we have been experiencing considerable changes in our expectations from engineering education programmes. Industry is undergoing fundamental changes and technologies face us with new challenges. We are also witnessing shifting patterns in the traditional club of economically developed nations. New comers are making their ways and force others to shift, re-allocate and accommodate them. There is one factor that is common to all, be it from developed, newly developed, least developed, or developing nations: and that is changing expectations from the engineering educational system. Such demands and expectations have forced all of us to re-examine our role, to redefine our objectives, to modify our system, and to use new tools.

Traditional curricula are undergoing fundamental changes. An early exposure to engineering challenges in parallel to learning the basic sciences is the cornerstone of today's modern innovative reengineering of engineering education [4,5]. The use of computers in the process of education can make this change a productive and a desirable one.

COMPUTERS AND EDUCATION

Computers can be extremely helpful in improving the basic skills. They have a number of advantages since they can provide the student with the ability to learn at his/her own pace without being disturbed by others' negative judgements on how slow or how fast the student is learning the subject. A more profound understanding of the subject would replace the sometimes shallow comprehension. Computers can also relieve the teacher of some routine tasks, thus provide him/her with the opportunity to consider special cases and to reflect on the coming challenges as well as to assess his/her achievements and failures.

Computers can help us to benefit from exploratory learning, while at the same time strengthen our abilities to develop basic skills. Creative research requires that the pattern of solving well-structured problems be broken. It requires to deal with problems that are much less structured compared to what we usually deal with in the class-room. An early exposure to engineering challenges is now feasible, mainly due to the capabilities that computers can offer. Here, the role and the impact of computers can be quite monumental and considerable.

We have experienced the use of computers and informatics in our graduate programmes. Students use computers to solve real problems and to produce final results very similar to what they would be making when they are working as engineers in the industry. One word of caution: we should not let the complexities of today's' computers to distract the students from gaining insight into the problem they are trying to solve. The objective is to use the computers in order to assist in the understanding of the subject. This objective should not be mistaken with learning how the computers work, or how complex they may become. For this purpose, special software packages that do not require extensive programming by students are essential. For two graduate courses, we have assigned to graduate students a task to develop easy-to-use, menu driven software that can be used by undergraduate students or working engineers to examine various alternatives and to compare them in a way that would broaden their comprehension of the subject. In one particular example, we were able to convey to students the behaviour of a system in three-dimensional space in a variety of conditions. We felt that a profound interest in the subject was inspired that was incomparable to our earlier experiences.

Computers have made other striking and considerable impacts on our educational system. Electronic mail and computer networking have made it feasible to benefit from unlimited resources and to obtain advice from cyber-space on the world-wide-web. One limiting factor has been the high cost of long-distance links to other sites on the network.

CONCLUSION

We have witnessed that students who have used computers as tools have developed a thorough understanding of the subject and are able to follow new developments. They have been able even to contribute to innovative approaches. Nevertheless, due to limited scale to our experience, one can not take it for granted that the same positive impacts we have experienced in our pilot programmes can be expected if they were to apply in a wide-scale use.

PRACTICES OF UTILISING NEW INFORMATION TECHNOLOGIES IN MUSICAL EDUCATION OF SCHOOL STUDENTS

V.V. Shtepa (Ukraine)

The emergence of hypermedia technologies combining hypertext and multimedia technologies has significantly increased the interest of teachers of the humanities to computer-aided training methods.

The problem of using computers in musical education currently arise numerous debates. Teachers of music today are not yet well familiar with computers and their capabilities. Therefore, they need to acquire new knowledge and skills to use computer technologies in the educational process. Obvious is the fact that the tremendous opportunities offered by computers should be utilised in all spheres of pedagogical practice including musical education.

Is the use of "musical informatics" mandatory for a teacher of music? The employment of computer training programmes affects the problems of innovation and creativity in the educational process. The problem of integration of new information technologies into the educational process leads to the necessity of revaluation of long-run objectives of school education as well as of selection of tools for setting and meeting those objectives. The school, lyceum, and gymnasium curricula give the definition of musical education objectives which suppose development of student's abilities to perceive the riches of the art through such phenomena as language, sound, shape, individuality, emotion rather than to acquire some theoretical and technical skills needed to a musician, i.e. a student is supposed to know rather how to listen and hear than how to create.

Courses of informatics as well as courses of music employing computer training programmes give students an opportunity to experiment with electronic sounds. The new information technology-based training methods are apparently free of any pedagogical strategies and their effectiveness depends entirely upon the mastery of a teacher. This brings up a problem of interaction within a triad: a teacher - pedagogical tools - a student. When the methods and tools are selected they play the role of linkage between a teacher and students.

The objects of the musical education are to help a student find his or her place in a constantly evolving sound universe, to satisfy and develop one's needs in self-expression and communion, to encourage one's imagination and creativity, to aid in understanding the variety of the sound world (including, certainly, modem music), utilising one's own potential and in finding oneself in innovative activities meaning various forms of musical expression (this is where the computer technologies can help greatly).

The selection of tools for this type of music lessons is the question of teacher's strategy, personal competence and interests to methods and media to be used by a teacher and students. Due to the lack of good training software in Ukraine it is only possible to count on fragmentary computer support for music lessons. The same computer-based musical training programmes can be used at different stages of musical education. The specialized schools of music can use various musical databases on CDs such as "Bolshoi Theatre", "Mozart's Magic Flute", etc. for the courses on music theory and music literature. The professional musicians can make use of a computer as a simulating and information search tool.

In addition, computer technologies offer the possibilities for storing and processing musical information. For instance, the machine classification of folklore works allows for not only storing but obtaining the information based on formalized qualities and parameters of song music and text. Such information-reference systems as UKRFOLK, the Ukrainian folklore songster, have been developed by the staff of the V.M. Glushkov Institute of Cybernetics (Kiev). In addition, computers are utilised currently for conducting research in the field of musical styles, genres, compositions, etc.

The application of computers in music classes of schools, gymnasiums, and lyceums is quite different. There was almost no consistent, goal-oriented attempts made in Ukraine to employ computers for musical lessons either at specialized schools or at comprehensive schools. However, the combination of capabilities of up-to-date computers and other means for transferring audio-visual information will definitely enrich the educational process. The modern information technologies provide for the following opportunities:

- accessing libraries of moving and static images with and without sound accompaniment;
- selecting of any required audio-visual information from databases;
- operating programme libraries;
- reshuffling information including texts, graphs, sprite-oriented diagrams, animation with and without sound accompaniment;
- multi-window data presenting.

All this variety of options will contribute in development of students' creativity initiative in the course of acquiring new knowledge, their ability to extract necessary information, manipulate this information, analyse and classify it.

This approach allows for completely different motivation and development level of acquiring new knowledge, comprehending new concepts and ideas.

The results of our research show that the computerization of the educational process should both aid in developing personality and creative capabilities of students and completely change the entire training technology.

The experience proves that the employment of a computer at class does not always produce that very effect a teacher counts on. This is explained by a number of reasons:

- absence of substantiation and appropriate methodology;
- difficulties of organization of subject lessons in computer-equipped classes;
- incompetence of teachers themselves;
- lack of broad-based software products meeting the requirements of all teachers.

In addition, the software available has both its advantages and weaknesses. On the one hand, it provides for a freedom of creativity, but, on the other hand, it does not answer the complex requirements of the educational process. It is necessary to conduct comprehensive research in Ukraine aimed at adaptation of foreign- and domestic-made software designed for lessons of music, develop the methodology for conducting such lessons, analyse the digestion of knowledge by students resulting from computer-aided classes. A teacher will have to solve a task of integral incorporating the computer technologies into the lesson canvas and developing new psychological, pedagogical and methodical techniques while preserving traditional ones which already proved their viability and efficiency.

There are some computer programmes designed for musical education which can be used as fragmentary support for one or two lessons. Other ones are data bases or encyclopaedias which imply that a teacher should select the necessary material for a certain lesson. These CD-recorded data bases can also be used by students for their individual work. Visual presentation of material provides for its easy digestion, the technology of retrieving the information from a CD allows for finding, reviewing, and selecting the information needed easily. These programmes give a student the opportunities to satisfy one's individual needs and interests, rapidly obtain brief information on specific subjects as well as to find supplementary information if desired. The practice of utilizing computer programmes at class prove the possibility for their integral inclusion into the educational process as well as the versatility of their application as they can be used for different purposes:

- explanation of new material;
- material reviewing and summarising;
- control over knowledge;
- work in creative music laboratories.

The use of computer support for music classes at the International Relations Lyceum of Kiev within the framework of 5-year experimental programme was combined with such traditional methods of training as discussion, work with literature, listening to the music, choir singing, and using other didactic means like handouts, illustrations, etc. Various forms of conducting music classes utilizing computer technologies were successfully added with different methods of teacher's organizational work: class work, team work, and individual work.

Taking advantages of computer music capabilities cannot yet be considered traditional for educational activities in Ukraine. However, a teacher can start with simple computer programmes such as music editors processing musical texts written by students themselves and proceed with more complex musicology systems designed on the basis of *hypertext technologies*.

The most interesting and promising tendency in employing computer technologies for teaching music is working with CDs based on *multimedia technology*. The growing interest to this technology is conditioned by a number of reasons. One of them is the availability of so called author's systems giving one an opportunity to create his or her own applied multimedia programmes even not having extended experience in programming as well as to combine several types of traditional (texts, table, pictures, etc.) and original (speech, music, film fragments, animation, etc.) information in one software product.

Multimedia technology is expected to be one of the major direction of enhancement of computer technology in this century. Nowadays, multimedia systems are successfully used in the field of education. Of particular interest for us are the computer-based training multi-systems allowing to enrich and deepen the students' knowledge providing gigabytes of information as well as to reduce the training time. The French lyceums, for example, already offer an experimental course called "Musical informatics and education" [1], taking which the students acquire knowledge either in information technology or in music. The experiences of experimental application of different music software demonstrate that such programmes as CD "Bolshoi Theatre" can be used for 5^{th} grade of comprehensive school for studying topic "Music and literature". The CD introduces the most known productions of the Bolshoi Theatre, its history and the people whose creative work brought fame to the theatre. Music, slides, and video fragments available at this CD let students to get an idea of many theatre's performances. Those curious will find a lot of interesting things in the appendix-glossary "Intelligibly about ballet" explaining various ballet terms in an easy form. The glossary is also illustrated with slides and video fragments.

Another CD programme "Maestro +, Create Your Own Melody" is also interesting and useful for the educational process. This programme is both entertaining and educational one allowing to create melodies and music compositions. It teaches to understand and differentiate main components of sound (acoustics), to rightly use them, and to develop and improve hearing perception through listening and analysis of various music.

The application of computer programmes at class is the creative process for a teacher as well. For instance, another programme called "Organ-grinder" offers children an opportunity to rapidly master musical notation through performing various assignments developed by a teacher according to the lesson subject. In this case computer is used as a fragmentary support. The students study musical ABC, simultaneously solving interesting creative assignments. Such lessons have a double objective of informing and developing creative thinking.

Teaching music we act based on the assumption that sound brings out our feeling and reaction to external world. It is necessary to help children communicate the harmony of sounds, feelings, and thoughts. Improvisation is one of the ways to achieve that. The students make up their own musical accompaniment to literature passages conveying the mood of poems through the sound, sound pictures and video fragments creating their own musical fantasy (it is also possible to draw under impression of music). The subject of improvisation is given by a teacher or suggested by students. This work can also be performed using a programme for IBM-compatible computers called "Musical-box". It allows one to choose a musical instrument which is best suited for expressing the specific plot (the programme offers 20 musical instruments). This package requires lesson-by-lesson work in the course of which the students will pierce into the secrets of musical language (melody, rhythm, timbre, etc.). The objective of such a lessons is to most precisely express the given subject and draw one's own sound picture. These lessons provide students with an opportunity to independently manipulate sound pitch and rhythmical relations which is next to impossible at a conventionally conducted class. The children (especially boys) develop interest to studying music as a complex concept. They want to get acquainted with more musical compositions, play musical instruments, sing.

The improvisation assignments enhance imagination, teach to think musical images translating them into real sounds. The lessons of music, efficiency of which increases through the use of computer technologies, open the boundaries for musical and art activities of students and allow to set up inter-courses relations combining music, fine art, and literature.

The new information technologies are very instrumental for creation of musical programmes. We are currently developing an information and training system called "A Fairytale in Music" (the authors O. Cheremis and V. Shtepa). The system is based on GIPSI hypertext system developed in the Hypertext System Laboratory of the Institute of Applied Informatics.

The application of this new programme at music classes makes the educational process dynamic and playful and lets a teacher to monitor the activities and knowledge of every student. When working with the programme a student is free to improvise that contributes to development of his or her interests and creative capabilities.

Therefore, the experimental work in this sphere shows that new information technologies can and should be used for teaching music. A teacher should analyse the PC capabilities needed for teaching the specific subject and the possibilities for its rational employment to increase and improve the students' knowledge. It should be stressed that great attention is to be given to development of new computer software for musical education purposes.

THE CHILDREN, DRAWING, SYMBOL, COMPUTER

T. A. Volkova (Russia)

Was it a god who charactere'd this scroll,
The tumult in my spirit healing,
O'er my sad heart with rupture stealing,
And by a mystic impulse, to my soul,
The powers of nature all around revealing.
Am I a god? What light intense!
In these pure symbols do I see,
Nature exerts her vital energy.

J.W. Goethe «Faust»

(Quoted from: «Goethe's FAUST» in two parts' translated by Anna Swanwick, LLD, London. George Bell and Sons edition, 1902. page 106. stanza 80 - 85)

Each person may be thought of as an individual world with its special knowledge, feelings, representations, which is to say that for each human creature the possibility is of vital importance for transfer of these knowledge and feelings to other people, both to those living beside him, and to his progenies. The whole history of mankind comprises the history of communication among both individuals and human communities.

The communications are connected with exchange of some information and assume some diversity of forms for representation and the ways for information transfer. The development of communicative abilities of children is closely connected to the language mastery process for such a dialogue. Universal languages of the communications are symbol systems.

In this connection the study of historically arising communicative technologies and determination of their place in the modern world are of considerable interest.

The pupils of 6-9 forms carried out a set of works on symbol systems by means of so called «method of projects» during optional lessons on informatics at Experimental Industrial Workshops (EIW) in 1992-1996.

The themes of the projects were as follows: «History of Writings», «Heraldry», «Symbolic of Ancient Russian Embroidery», «All Flags Visit Us», «History of Advertising», «Festival of Numbers».

The result of the above works is the set of computer programmes for chosen themes.

METHODS

At all variety of chosen themes during the work over each project it is possible to allocate general stages.

SEARCH. Reasoning from the requirements of the educational process, a teacher chooses the theme and carries out scientific and pedagogical research, which can be used in the development of the given theme.

CHILDREN. WORK ORGANIZATION. Those children are invited for project development who want to work with computer. The age of the children is thus taken into account: 11-12 years (a group of the beginners), 12-14 years (a group of those who continue the work with computer), experience of work with computer and experience in drawing are also taken into account. Each group of children works over one project during an academic year.

TECHNOLOGY. The pupils study fundamentals of computer graphics, they learn to use «mouse» manipulator, «Graphic editor» programme, operations with scanner and computer networks; the issues connected with drawing and painting are also considered.

PROJECT EXECUTION. The novelty, actuality and importance of the chosen theme is discussed with pupils, and the fact is emphasised that the work is collective, in which each pupil makes its contribution. The scenario of the programme is further made. The program represents computer analogue of an album, consisting of slide pages, over creation of which children will hereinafter work.

With the purpose of acquaintance with the chosen theme and selection of work material the pupils visit museums, look for information in various books, encyclopaedias and dictionaries.

The work shall be planned in the process of execution of individual tasks by means of computer. There are special requirements for slides. When the work over project approaches to completion, the following components of an album are made out: cover, epigraph, menu, conclusion and slide of the participants, in which all authors of work are listed. Then the whole album is assembled with help of the «Scenario Editor» programme, and the pupils prepare their report that comprises demonstration of the completed programme.

PROJECT DEMONSTRATION. The children invite their parents, friends, and also teachers for the presentation of completed project. During project presentation the achievements of each pupil are emphasised and successful overcoming by him of arising difficulties is demonstrated. Aft presentation each pupil is awarded.

PROJECT DEFENCE. The completed projects/programmes were presented at «Search-95» and «Search-96» research and practical schoolchildren conferences at «New information technologies» section. The pupils prepared the reports, programme demo-versions and presented their reports during the conferences. The submitted projects were marked by the diplomas, the thesis of the reports were published in the materials of the above conferences (it was the first published work of each pupil), the authors of the projects are awarded by souvenirs.

PROJECT IMPLEMENTATION. The programmes can be used as a training material at the lessons of history, geography, literature, Russian, Informatics, technology, mathematics, sewing work and fine arts; they can also help a beginner in the field of advertising.

Now the above programmes are used in educational process at EIW and at schools of Moscow and St-Petersburg.

Those pupils, who attend optional lessons, take part in «Young artist» magazine activity together with their teacher. Their drawings illustrate the articles on fundamentals of computer graphics in «School for beginners» heading.

The works of the children were demonstrated at various seminars and presented at «Children - Art - Computer» exhibition within the frameworks of «Synthetic intellect in 21st century» International Conference in Moscow (1995).

Implementation of the proposed method gives possibilities for realisation of the active approach in the course of educational process and enables a teacher and a pupil to carry out joint creative work.

PROJECTS SUMMARY

«HISTORY of WRITING» programme comprises an album, telling about the history of writing by means of pictures.

The writing is really ranked as one of the greatest cultural achievements of the mankind. That is why both the knowledge of history of writing and its interpretation are so important.

The writing may be defined as a symbol system for speech fixing through which information transfer by means of graphic elements and information saving can be carried out.

The well-known examples of four kinds of writing are presented in the album. They are as follows: pictographic, ideographic, syllable (word - syllable) and letter-sound (syllabic).

Further development of writing has resulted in creation of the alphabetic writing systems. The first European alphabet was the letter symbol one. It was developed by Phoenicians.

Both the scheme of writing system development and the examples of ancient Greek and Latin alphabets are presented in the album.

A separate chapter of the album is devoted to the history of creation of Slavic writing system by Bulgarian educators, brother's Kirill and Mefody. Presented in the album samples of Cyrillic, Glagolic and Uncial (Writing) of «Ostromir's Gospel» (1057) were made by means of scanning and further editing with the use of special graphic programmes. *(Ostromir's Gospel is the first Russian Gospel with established date, 1056 - 1057. Ostromir was a governor of Novgorod. He ordered to rewrite the Gospel in Russian. Comments of translator).*

The program «HERALDRY» represents an illustrated album, telling about heraldry.

Heraldry is the special historical discipline studying the system of the coat of arms and of knowledge of them.

The purpose of initial acquaintance with heraldry is to get an opportunity «to read» the coat of arms, to classify it and to decipher its coded information.

Heraldry plays an important role in determination of the origin of historical monuments, supplied with the coats of arms. It helps to find out the authenticity, fitting, authorship, time and place of manufacturing of mode of life subjects, art, books and manuscripts.

The basic elements of a coat of arms are a shield and an image on it. From the representational point of view the shield appeared to be rather capacious system for information record and transfer.

The scanned images of the redfigure seal of Ivan the Third and ancient Moscow coat of arms are included into illustrated story about heraldry.

The album is supplied with the images of the coats of arms of the cities the Gold Ring of Russia. This part of the work was carried out on the basis of the reprinted edition of «The Coat of Arms of Cities, Districts, Areas and Settlements of Russian Empire», (St-P, 1900) by von P.P. Vinkler.

The program «SYMBOLICS OF ANCIENT RUSSIAN EMBROIDERY» represents an album, telling about the surprising phenomenon in a global history of arts that is ancient Russian embroidery.

The mode of life of the ancient Slavs was firmly connected to applied art that is wood fretwork, colourful embroidery, intricate woven patterns. Towels, table clothes, the clothes, head dresses were decorated with embroidery.

The language of Russian national embroidery is the sort of the system of writing, where ink and paper are replaced by canvas and a thread, which is frequently red.

The deciphering of the symbolical images of embroidery elements was among the objectives stated by the authors of an album with the purpose of « reading the texts» written on canvas by means of a thread.

With the help of Russian national embroidery we can imagine the mode of comprehension of both the world and the nature by the ancient Slavs and penetrate into the depth of their national poetic mythology.

The story about symbolic of ancient Russian embroidery is illustrated by drawings of embroidery samples and supplied by explanation of the basic elements. The samples of embroidery are accompanied by the explanations from the catalogue. The album is supplied by an attachment «Some secrets of drawing» by means of which one can follow the process of creation of children's creative work.

The program «ALL FLAGS VISIT US» represents an illustrated album, telling about the flags.

The album consists of several chapters. The first one is devoted to a special historical discipline dealing with the history of flag origin, i.e. to vexillology. The chapter «All flags visit us «tells about the history of Russian flags and is supplied by the drawing and descriptions of flags of international organisations such as UNO, Red Cross, Olympic Games etc. International Status-Book of Signals, which is used for communications on sea and also the flags of some states of the world are also described.

The «HISTORY of ADVERTISING» programme constitutes an illustrated album, telling about the origin and development of advertising as of a symbol system. In the album the examples are collected of various representational and verbal means, used in advertising.

The album is opened with the chapter «Childhood and adolescence of advertising». In the above album there are considered protoadvertising and various forms of advertising, which existed before the rise of the written language. Such concepts as catalogue, summary and publishing mark are explained with the help of the example of development of advertising with appearance of bookmaking. The next section is devoted to the history of advertising in Russia. Examples of splint, poster, bill are presented, the advertising by V. Mayakovsky is examined. Then the concept of company style is investigated.

«The Dictionary of Advertising» is the important part of the above album; it contains about 40 terms and definitions, supplied by explanations in the appropriate sections of the programme.

The program "HOLIDAY of NUMBERS" in the entertaining form tells about a history of occurrence of figures and various notations, about the first adaptations for the accounts.

The composition of all albums includes a cover, epigraph, illustrations and explanations to a considered theme, conclusion and slide with enumeration of all participants of work further follow.

All programs are prepared with the help of a graphic package CPEN, they occupy volume 450-800 Kb everyone and are started in MS DOS on IBM PC. The programs-albums "are going through the pages" by a key "space". The choice of the unit of the program is carried out with the help of the menu and sub-menu. An exit from viewing is *Esc*.

COMPUTER CREATIVITY: DEVELOPMENT OF ART ABILITIES OF CHILDREN AND COMPUTER ARTTHERAPY

N.V. Volodina-Panchenko (Ukraine)

As experience shows, the computers can play a significant role in training not only schoolboys of younger forms, but also pre-school children. Already from five years' age children can successfully master and use the computer as the tool for the writing, drawing, as a whole - for development of creative thinking. It is necessary to emphasize, that in training with the help of computers the speech should not go only about study of a necessary educational material. The computer training should promote all-round and harmonious development of the person, first of all of its creative abilities.

We consider the training to art creativity as the important component of formation of individuality of the man.

Experimental researches, which were carried out on preparatory and art departments of Children's school of arts № 2 in Kiev, have proved that use of the computer as new, modern means in training of pre-school children and younger schoolboys to principles of art creativity and fine art is very much expedient and perspective.

20 children in the age of from 4 up to 6 of years and 40 schoolboys 7-10 years learning I-III of forms of Children's school of arts and comprehensive schools of city took part in the experiment (at the desire of children and at the consent and support of research by their parents).

During an experimental research, which began in January, 1995, we had an opportunity to be convinced that the computer, though is object of technical environment, enters very successfully into synthesis with traditional, natural environment of school of arts, harmoniously supplements this environment and considerably expands opportunities for intensive, emotionally active introduction of the child in the world of art and art creativity, promotes expansion of consciousness of the child and formation of sincere keenness. The bases of information culture imparted to the pupil, considerably optimized educational process as a whole, have raised interest of the pupils to training.

At lessons the computer training and developing programs developed by the domestic and foreign experts and presented by the Ukrainian Foundation of educational software were used.

Both individual and group (small groups in 4-6 schoolboys) lessons on the personal computer with children once a week were carried out. Teaching on author's techniques of such art disciplines, as the art creativity for pre-school children, basis of painting and composition (for younger schoolboys), very successfully supplemented the traditional forms and methods of training to fine art.

The computer gives the teacher an opportunity to use widely a method of art - pedagogical playwriting on each lesson. At these lessons music, fine art, the literature and history of art harmoniously incorporate, and, as a result, the child is directed by the most optimum way - through all-round aesthetic education - on a way of independent creativity. The little schoolboys are trained not only to draw on the screen of the display, but also to duplicate the drawings, to supplement their compositions by the texts of own poems, fairy tales, stories, creating unique monochrome and multi-colour art - graphic compositions.

The modern computer programs for drawing and designing (graphic editors) enable the child to use any art material, which computer can simulate in perfection, - pencil, felt-tip pens, ink and pen, various paints, backgrounds, etc., creating figures, applique works, photocollages, and also to work at graphic forms, painting, design.

The teacher has fantastic opportunities for operative realization of his (her) creative conceptions concerning preparation and manufacturing of visual aids, teaching materials, creation of methodical collection of the best children's drawings etc.

We developed and prepared for the edition by trial circulation the learning manuals (on art creativity, drawings, computer design) both for the work during the lessons and independent training for the children (age from 5 to 10 years) who have a possibility to operate with a computer at home, and for those who prepare to meet a computer in school.

At the lessons of fine arts the implementation of the computer support results in the growth of knowledge level and capabilities of junior pupils. As an instrument, a computer promotes children activity and more profound understanding of the main concepts of drawing, composition, as well as of such section of painting like colour management.

The exhibition of computer drawings as a result of our successive work with learners proves that the use of a computer promotes the appearance of children's attention and interest to various aspects of national culture (folk songs and dances, dress, architecture and way of life, traditional trades and others).

On the basis of research results the first artistic and methodical exhibition of children's computer drawings was held in Ukraine (more than 300 coloured and black-and-white compositions, printed by laser printer).

Thus, the use of computer technique at the lessons of the fine arts can provide:

- significant increase of an efficiency of knowledge mastering on the basis of training intensification and optimisation;
- real opportunity for realisation of personal approach in education owing to its wide range of training and controlling possibilities;
- both supplement to the traditional methods and techniques of fine arts training and wide range of new possibilities along with formation and development of artistic capabilities of pupils;
- good incentive for the development of intelligence, thinking, creative erudition of pupils, accustoming the foundations of information culture;
- favourable conditions for fostering a continuous interest to national artistic culture, national folk art and fine arts as a whole.

We believe that in the process of artistic and creative evolution of a child a computer can not (and must not!) substitute the traditional training technologies. It must be used in a training process as a modem tool, implying the richest possibilities for diverse creative uses.

Our experience shows it is possible to develop, train and cure children through balancing their psycho-emotional state by means of new information technologies.

In medical quarters art therapy (or therapy by fine arts) is a well-known term for a long period of time. For specialists the possibility is now quite evident for successful medical treatment by means of fine art, psycho-emotional correction of children and adults with the use of harmonic music, spontaneous dancing, meditative drawing and painting or the combination of these arts. In the field of medicine and psychiatry art therapy is actively implemented both abroad and in Russia, though in the last case to a lesser extent.

Recently a new trend arises in medical treatment by art therapy that is computer art therapy supplied by the traditional methods and techniques.

The children with psychiatric breakdowns initially are as if being condemned to spiritual and information deprivation, since their education and training are traditionally oriented to their defects. In Kiev Research Institute for Common and Judicial Psychiatry the work was carried out with application of non-traditional methods of training and development through computer possibilities during 1995 for children and youths with various psychiatric deflections. The evaluation was conducted by means of a complex of clinical and psychopathological and neuro-physiological methods.

The traditional training in school have been pursued with word and sign system prevailing, oriented predominantly on left brain hemisphere, that leads to overlapping of all other sensor and motive perception channels and, to some extent, it is a reason for unidirectional brain evolution with the use of precisely those its structures and functions which are imperfect in our patients. In our case the attention was concentrated on a complex development of right- and left-side brain hemisphere functions along with training and balancing of psycho-emotional state according to methods which were expressly elaborated by authors. The work was accomplished according to the following directions:

- development of artistic capabilities by means of the specially elaborated techniques of computer graphic and elements of computer animation;
- development of children cognitive abilities by means of evolving computer games and training programmes.

42 persons (children and youths of an age from 3.5 to 15 years) attended the training and medical treatment course during 3-4 months.

As a result of computer art-therapy application the children and youths had revealed the similar dynamics of change in psychiatric state.

The children had been overcoming their internal barriers, psychological discomfort, states of psychiatric deprivation, and neurotic states. They became able for individual growth and development. The possibility for access to computer technology had caused (in 100 % cases) the increase of positive consciousness and the formation of positive part of «I - concept». In the course of training with the use of a computer the estimation had been changing of the children by their parents to positive direction, that improved the relations between children and parents and created a favourable family microclimate.

There were observed the growth of motivation along with fulfilment of training tasks, the development of volitional features while reaching objectives and the overcoming of technical «non-ability». The need was intensified in contacts and interaction. Such creative capabilities as independent vision, combinative, searching activity, as well as emotionality and ability for co-feeling and spiritual demands were improved.

The perception was changing, that is, the following characters were formed: a delicacy of differentiation of artistic images and environment, the space feeling and special perception. Also, the increase was noticed of ability for independent concentration of attention and independent regulation of activity. The memory improved, the volume of short-term memory grew. The motion co-ordination improved, the formation of fine differentiation motor system occurred. It is of general experience that the above facts indicate the extent of puberty of brain structures.

The method of computer art therapy has a lot of priority features as compared to conventional methods of psychiatry. The method comprises harmonically and independent creative power of a child (that serves for him as self-expression and exteriorisation of accumulated problems) and the fulfilment of specially structured tasks, affecting the functions of various parts of brain. The balancing of mental and emotional state of a child occurs. In the course of training the complex effect of the following factors takes place: emotional and well-meaning contact with pedagogue-psychiatrist; influence of specially selected music; independent activity of a child; developing and training computer programmes.

Great potentialities of computer programmes allow sustaining a child's activity in the «zone of the nearest development» (according to J.Vygotsky). Thus the situation is formed of concentration and training of resource capabilities of mental processes, stimulates their development and allows preserving the situation of success and achievements. In the course of computer art therapy accompanied by neuro-physiological control it is indicated a significant restructuring of bioelectrical brain activity.

The use of new information technologies in the course of training will give the positive effect only in the case of fulfilment of the recommendations of psychiatrists and hygienists regarding to work organisation with microprocessor technique.

TECHOLOGIES

ELECTRONIC BOOK AS A MEANS OF COMMUNICATION UNDER CONDITIONS OF INNOVATIVE TEACHING

V. N. Agueev, E.A. Klimova (Russia)

A characteristic feature of the modern stage of informatization in the sphere of education is a qualitatively new stage in the development of hardware and software designed for the application in teaching. This is primarily manifested in transition from the use of personal computers for their solution of purely computational applied problems to their application as means of information and methodological support of one's own learning process. One of the most promising trends in this direction is a search for the ways of the creation of computer systems designed for individualization of teaching, taking into account the creative and psychological properties of the student.

A transition to innovative teaching implied the presence of four major aspects of the reorganization of the management of the teaching process [1]:

1. a transition from a peremptory role of the teacher to democratic co-operation, aid, inspiration, relying on the personal initiative of the student and the growth of his personality;
2. change in the process of knowledge assimilation: transition from routine learning to the organization of productive creative process in the diversified forms of thinking;
3. focus on the social nature of any learning and development of the personality;
4. elimination of the destructive role of marks, which focus on the striving to attain a pre-set standard in actions and behaviour and invariably resulting in conformism and lack of individuality in students. Whereas the conventional approach to the problems of teaching is predominantly aimed at special knowledge transfer from a tutor to a learner, the innovative approach is characterized by a focus on the development of both personality and various thinking types of each learner during the learning process.

Whereas the conventional approach imply such traditional types of teaching as simulation, imitation and following the models, the innovative approach is based upon the great variety of interactions that promotes actualization of personal experience of each learner. In each particular case of the innovative approach the leading type of communications is that providing the best possibilities for achievement of high activity level for each learner.

From the aforesaid it might be assumed that that at least two problems shall be solved with the purpose of transfer to the innovative teaching principles. They are as follows:

- Firstly, the teachers themselves shall be trained in implementation of the new work methods, new technical means and computer technologies.
- Secondly, a teacher needs special technical means that provide both efficient co-operation with a group of learners and possibility for control and management of the process of learning without suppression of self-expression liberty of a learner. Being modern and efficient communication mean, electronic book is one of such technical means.

In the literature dealing with new information technologies and modern means for communications we meet such terms as "electronic book" and "electronic edition" with increasing frequency. Though meaning of the above terms is not is not yet defined precisely, the great majority of the authors take these terms to mean quite distinct sense, i.e. referred to some subject area the set of texts, illustrations or various musical or conversational fragments which are written on a digital carrier, for instance, on a laser compact-disc. In addition to data carrier we need special hard and soft wear to read such a book.

The recent years have seen an advent of a large number of electronic publications which content is invariably associated with learning. Great variety of teaching systems, such as electronic encyclopaedias, dictionaries, simulators, etc., falls in this category (see, for instance, *Transactions* [2]). Along with that we should emphasise that among the philologists and book-keepers the opinion exists that electronic book has no advantages as compared to conventional "paper" book (or hard copy) from the point of view social communications, particularly when it is used in course of teaching humanities. A sceptical attitude of some specialists in humanities to the possibilities of computer means of learning appears to be associated with the fact that the authors and developers of the software pass over the old methodological method to the medium of new information technologies. This results from the lack of conceptual approach to the issues associated with the creation and development of the electronic book.

An integrated approach to the electronic book problem implies an investigation of the man-computer-information environment system, where the man is a major component. It follows that the development of the systemic principles of developing a friendly and efficient dialog is associated with an integrated study of psychological, semiotic, ergonomic and other aspects of the communication of the man with the computer.

The computer system forms a communicative system of interaction with the man, where information is exchanged in the symbolic form. A basic requirement to the developers of such a system is an efficient solution to the user's interface problem. Its solution involves at least two approaches.

The first approach is based on the user having the opportunity of understanding the essence of a man-made system, to easily learn and memorise the rules of handling it. The second approach is based on the intention to render the work of the user with the intellectual system an interaction between equal partners, the man using the language environment and the metaphor system well familiar to him, and the computer having the task of supporting the user, taking into account the peculiarities of his behaviour in the course of interaction. Practically, the problem of the interaction of the user with the communicative systems is handled on the basis of a compromise between the above two approaches.

In the 1970s, a view was widespread that it is only the natural language that would ensure the most convenient method for the man-computer communication. This assumption was relied upon to create the «fifth generation» of intellectual computes. But the correctness of this assumption is far from being self-evident. The natural language (even on condition of absolute understanding of the utterance meaning) would not always ensure the completeness of a description attained, for instance, when contemplating the image of a fairly complicated object.

It has become evident now that an effective interaction of the man with the computer is only possible on condition of the use of different communication languages, including those activating the image mechanisms of thinking (iconic language, the language of actions, musical and colour codes, etc.). This is supported by a widespread distribution of systems based on new technologies of multimedia and virtual reality, simulators and other software, whose dialog component relies on active use of computer graphic methods.

The problem lies in the fact that the symbolic and language means of the dialog are often used by the developers subconsciously, intuitively, without due knowledge of the problem of user's interface. The programmers, normally focus on the functional characteristics of the software, neglecting the user.

The reason for this state of events is readily understandable. Firstly, the users do not expect much of the software offered to them since they are unable to adequately assess its quality. Secondly, the programmers are not competent enough in creating users' interfaces.

It took some time to realize, that the problem of the man-computer interaction is integrated, requiring joint efforts of different specialists, and that the man is the basic, and the most complex component in the man-environment-computer system. A new scientific discipline has appeared: a human-computer interaction, where new research specializations are actively developing. These, for instance, include computer semiotics, whose purpose is analysis of computer systems in terms of their use as signs interpreted by the users depending on their intentions and ergo-semiotics (it is treated in detail in the monograph [3]).

The informatization of the society on the basis of massive advent of the computer technology is an irreversible process, but this is primarily a process but not a single action. It appears that it would take much time before the fruit of computerization become manifest. Its present stage is only initial one. Irrespective of the scale of the problem of transformation transfer from the paper environment to the computer, it will have to be solved, otherwise all the talk on informatization will remain mere talk. The first attempts to solve it are already there, and they are fairly successful; it is expected that by the year 2000 in the USA all the publications will be accompanied by their electronic versions [4].

NEW EDUCATION TECHNOLOGIES IN ECONOMICS AND MANAGEMENT

Y. N. Alexeyev, V.V. Godin (Russia)

The present-day situation in Russia dictates the need for training, including in service, workers in the fields of economics, business and management.The task is fundamental revision of the learners' views on the principles of economic operation, as well as instilling a system of values, views, skills and knowledge that would comply with the dictates of the present-day market economy. Hence the urgent need for changing the technologies of the teaching process and the range of fields of professional training. Currently, both classical university education in economics and management and the "long" and "short" educational programmes of various business schools are carried out in certain conditions as described below.

For one thing, there is a limited number of specialists capable of providing training up to the international standards, especially as concerns economics and management. The seeming simplicity of the principles of market competition or operation of the stock market is deceptive, in fact. There are surprisingly few instructional programmes that go beyond purely theoretical rendering of customised educational resources.

The second factor is the shortage of time allocated for in-service and/or other retraining courses. Significantly, the training time is limited both at the macro-level (in the sense that the constructive changes in the economy and management should be carried out in the shortest possible time) and the micro-level (the level of individual manager or administrator). Those engaged in practical management, in small-scale private business in particular, would virtually "steal" time from their occupational duties, and hence their in-service training time has to be as short as possible.

The third factor to be taken into account is the shortage of retraining funding. The educational programmes are fairly expensive, while the payment rates even of the best qualified teachers and instructors are still below the world standard. Applied to an individual, the problem could be defined as follows:
under socialism, the life style did not call for purposeful saving or significant expenses on education, hence the need for a radical social and psychological reorientation. In the current conditions of transition to a market economy, investments in personnel education and occupational training is a very risky form of investment with a long payback period - and consequently very low priority.

These factors necessitate the use of such forms of occupational training as evening, correspondence and distance. Many of the university and college teachers and instructors in Russia have developed a negative attitude to correspondence education in the mode which existed in the former USSR. We believe, though, that life dictates the revival of this type of education, but in another form - that of distance education which would incorporate Western technological achievements as well as some features of the Russian traditional educational system. The advantages offered by the application of distance education today lie in the fact that its application makes it possible to use a relatively small number of qualified instructors for training a large number of managerial workers and other specialists. This type of training is cheaper than the training involving full-time attendance, and besides, it allows to combine occupational training with the conduct of occupational duties.

Today, the learning technologies of any type of training for the work in economics or management should be based on informational technologies, such as the computer, audio and video facilities, complete with respective courseware. Creating common informational environment for the learners, exposing them to the use of informational technologies for the study of most of the general disciplines, as well as specialized courses, figures as an important factor. The learners must be provided with various tools, such as word processors, electronic tables, economic information analysers, statistical packets, etc., and various automated training systems for individual work. The major problem here is, not so much the technical base as the correct choice and development of software, as well as adequate qualification of all the teachers and instructors.

An important factor of the training for business, management and economics is the availability of a computer modelling test-field for evaluating theories, verifying hypotheses, etc. In this case it is reasonable to use a more or less universal computer modelling system with an open aggregation of models instead of separate simulator models of various objects and phenomena.

A modelling system is a tool for making simulator modelling an everyday activity which is available any PC user. The application of computer programmes of this type to the learning process requires a high level of training and qualification and a desire on the part of the learners to familiarize themselves with the functioning of economic mechanisms within the limited time period allocated for the purpose. The IMITAK system, worked out by the State Academy of Management, can be used as the basic model for instruction in most of the economics and management courses.

This modelling system represents a modified version of the method of systems dynamics and provides for the following objectives to be obtained within the mode of a friendly dialogue with the user:

- broad-class simulator models with a feedback;
- computer experiments with the models, with screen display of the results;
- a user training mode of modelling methods.

Three versions of the IMITAK system are used in the educational process:

1. the version for conducting tests with standard models of processes and phenomena;
2. an instrument for the professional development of simulator models by teachers and learners to be applied for research in the fields of economics, social systems, etc.;
3. a facility for providing computer support to the study of various processes and phenomena based on the learners' building the models on their own.

Various dynamic models - economic, social, technical and others - may serve as objects for modelling. Since it is so easy to change the models, they are always adequate to the task despite the changing economic situation. Standard models and those built by the learners, along with case studies, underlay practical and individual studies of the learners at various phases of the learning process.

WORLD PLANETARY DATABASES INTEGRATION. USERS ACCESSIBLE EXPANDING POLICY

R. Arvidson, F. Shayres (USA),
N.S. Kasimov, R.O. Kuzmin,
M.Ya. Natenzon, V.I. Tarnopolskiy,
N.F. San'ko (Russia),
G. Neukum (Germany)

STRATEGY ASPECT

The mankind have collected huge amount of knowledge about other planets. This knowledge need to be saved for the next generations and became not passive, but active through education.

We believe that those people who will not know the geography of the Moon, Mars and Venus could not be called "educated" in the XXI century.

TACTIC TODAY

The interest of young people to the precise and natural sciences has decreasing now. This tendencies becomes critical, especially in space and planetary researches.

However this tendency can be compensated by rational use of the modem information technology for more and more easily access to data and knowledge, especially in such interesting area as Solar System exploration and exploitation. The solution seems to be the usage of such well tested approach : the involvement of schoolchildren into the direct work with leading scientists at the largest science centers. But now because the usage of computer and communication technologies, the opposite procedure becomes possible: to bring knowledge and experience of the leading scientists closer to the young people. So more people can be involved.

TECHNICAL ASPECTS

• Now the real work with huge volume of collected by different counties planetary data in its present form is difficult even for scientists - planetologiests, not only for schoolchildren and students.

• Some information on planetary data received by old space missions need to be not only restored and saved, but — recovered.

SOLUTION AND ACTIONS

The solution is to create World-wide Accessible International Planetary Data Base for Science and Education. The main differences of this database from existing archives will be:

• knowledge level users orientation - from schoolchildren to scientists,
• map-oriented access technology usage,
• hypertext technology usage,
• multimedia technology usage.

The activity in frame of implementation the solution is providing by IKI (Space Research Institute), Russia and Washington University, USA in closed collaboration with

• IPE Institute of Planetary Research), DLR, Germany
• JPL (Jet Propulsion Lab.), USA,
• Vernadsky Institute, Russia,
• Moscow State University (MGU), Russia,
• Moscow Geodesy and Cartography University, Russia.

THE FIRST STEPS:

• creation of International Mars Database included mainly the data from overed missions «Mars», «Viking» — and «Phobos» missions, also the future missions «Mars-96» and «Mars Global Surveyor»,
• creation of International Moon Database included mainly the data from overed programs «Luna/Lunokhod» and "Clementine".

SOLAR SYSTEM PLANETARY DATABASES STRUCTURE FOR EDUCATION

R. Arvidson (USA),
T.S. Kirsanova, M.Ya. Natenzon,
V. I. Tarnopolskiy,
K.B. Shingareva (Russia),
G. Neukum (Germany)

THE MAIN EXISTING SOLAR SYSTEM PLANETARY DATABASES AND DATA SETS FOR EDUCATION

1. HTML-programs accessible via Internet that work with the data found on the World Wide Web:
- "Welcome to the Planets"
- "The Nine Planets"
- "Solar System"
- "Mars Atlas"
- "Martian Space Science System"

etc.

2. Educational CD-ROM with the best images collection of Solar System Planets.
3. CD-ROM collection with Martian images of "Viking" mission: full professional set.
4. Planetary missions images archives stored in different US PDS nodes.
5. Catalogs of HTML-programs for quick search of images in archives: "PDS Clementine Navigator" – for "Clementine" mission to the Moon. "PDS Mars Navigator" - for "Viking" mission to Mars.

FUTURE WORLD-WIDE ACCESSIBLE INTERNATIONAL PLANETARY DATA BASE FOR SCIENCE AND EDUCATION. PRINCIPAL FEATURES

The main differences of this database from existing databases and archives will be:
- easy to use: attractive and user-friendlydialog interface,
- integrated systematic approach,
- knowledge TV-users orientation - from schoolchildren to scientists,
- map-oriented technology usage,
- hypertext usage,
- multimedia technology usage,
- more pictures.

DEVELOPMENT OF "MULTIMEDIA" TEACHING AND LEARNING ENVIRONMENTS IN AUSTRALIA: DESIGN PERSPECTIVES

J. P. Bell (Australia)

ABSTRACT

Examines informatics and its application in tertiary education in Australia. Analysis, design, implementation and use of interactive multimedia (IMM) tutorials are discussed and a number of examples are described. Important issues that relate to the effective design and implementation of informatics in tertiary education are identified and future areas of research are suggested.

KEY WORDS AND CONCEPTS

Informatics in tertiary education; Requirements Analysis; Information Technology in Education; Multi-Media Teaching and Learning Materials; Software Engineering; Curriculum Design.

EFFECTIVE USE OF INFORMATICS IN EDUCATION

What does effectiveness mean when it is applied to the use and adaptation of technology in tertiary education? Teaching things that we always used to teach to more students more cheaply? Using technology to extend the possibilities of what we can possibly teach? When the telephone was first invented it was thought that the most useful purpose to which the technology would be put was as a broadcasting technology. Early testing of the technology involved a number of testers at different locations holding phones to their ears listening to a broadcast of an opera! Uses of telephony have come a long way since then, although early experiments were necessary stages along the way. Some of these were unsuccessful, but as for any new revolutionary use of technology - NITs being no exception - the lessons learned from each step provide the means to take the next one.

In the Department of Computer Science at RMIT in Melbourne we are using and evaluating a number of implementations of NITs to support our teaching. By these developments we wish to define the important design issues, to investigate the appropriateness of various software development methodologies and to examine the potential of a variety of delivery platforms. In one initiative, we have been developing IMM (Interactive Multimedia) materials for approximately 12 months. We teach a large number of Australian students who have recently migrated from non-English speaking countries as well as a considerable number of international students. Typically, a significant proportion of these students experience some difficulties with understanding written and spoken English. Our first development for this, was a small project that aimed to improve our effectiveness in delivery of courses to these students. To assist students to understand course terms and concepts, who otherwise would have to rely on reading lengthy texts when revising, we decided to investigate the of IMM authoring software. Using Asymetrix Toolbook authoring software, we developed and distributed an Interactive Multimedia (IMM) online reference for the second year course entitled "Data Modelling and Relational Databases". This application, which has now been developed, uses hypertext, graphics and keyword(s) searching to assist the students to develop an understanding of important course concepts (for example the Relational Data Model and application of Structured Query Languages).

The tutorial software was distributed to students on two floppy diskettes and can be run on a 386DX PC (or better) that uses Microsoft Windows. At the end of the course, student evaluation of this package was carried out. All students indicated that they had found the tutorial was useful. As well as providing easy access to explanations about the concepts and terms that had been covered in the lectures they had found the electronic reference to be very helpful when revising. As a result of this development we learned a lot about the use of appropriate development methodologies and delivery platforms for IMM tutorials . When we first started the project however, we had little understanding of the capabilities of the software and although we were not devoid of educational training, we still failed to understand how educational theory should inform the design of IMM tutorials. In our initial design of the tutorial, we needed to develop more imaginative ways of looking at the knowledge structure that we wanted to elicit, and to define how the 'knowledge' should be presented to support this.

Teaching of programming and programming principles is a major part of the Computer Science undergraduate degree and is the focus of a lot of the teaching effort. Having learned much from our first IMM tutorial, we are currently using Asymetrix Toolbook to create a tutorial module that simulates the operation of data structures in computer programs. The first module - which is now developed - demonstrates the workings of a binary tree. Students are able to generate numbers randomly then each number can be dragged and dropped into a node of a graphical representation of a tree. The system checks correct and incorrect placements of numbers and provides diagnostic assistance. We plan to use this module as the beginning of a larger tutorial that uses simulation to explain the various levels of abstraction that are involved in operation, design and implementation of computer programs: how computer programs work; generic aspects of program design and implementation; and examples of implementations of these aspects in a number of programming languages. Interactive tutorials that utilise simulation provide a unique vehicle for demonstrating concepts that are hard to visualise. Phillips [5] points out that simulations provide unique opportunities to communicate specific kinds of information to students. He cites a number of examples of these - dynamic processes in which it is important to understand the relationships of moving objects; communication of subject areas which have a broad context and in which a number of ideas need to be linked to form an understanding of the whole (not just the parts); and simulations of expensive, complex or dangerous processes. It is intended that as modules are developed that they can be used on their own or in combination with other modules that have been developed. We are planning the navigational structure of the module to support novice and advanced learners so that novice programmers can be guided through the tutorial material step by step using a linear, hierarchical navigational structure, while intermediate or advanced students will be given some opportunity to browse the tutorials more freely should they wish to.

For a different subject area, an implementation in the Faculty of Nursing at RMI.T provides another example of the use of simulations that aim to provide students with practice in making patient assessments. Animation, sound, graphics, text and full motion video are used to convey patients' conditions and case histories. The material requires students to make diagnostic assessments and to recommend appropriate courses of action based on these. By this, the students are given the opportunity to treat dangerous conditions without the risk of losing the patient. One of the case histories, for example, simulates a heart attack patient's condition and students are required to diagnose the condition and to recommend treatment. In order that the situations are as true to life as possible, a lot of video and sound files have been included in the completed application. These require large amounts of storage space and processing power and therefore the software has been distributed on CD ROM. Tutorials are provided for students' use in a specially equipped laboratory of multimedia Pentium PCs with CD ROM drives, video and sound cards and headphones. As our experise in this area develops, we wish to gather evidence about the effectiveness of IMM tutorials in providing quality educational outcomes for students. We also wish to investigate what effect factors such as subject area or learning task complexity have on design of IMM tutorials.

Estimation of the cost of the IMM tutorial development is an important issue when deciding upon its feasibility. The Science Multimedia Teaching Unit at the University of Melbourne for example, has been developing tutorials to replace 'wet' laboratories that were provided to first year Chemistry students. Approximately 1500 students (many of these studying Chemistry from other courses) study Chemistry in first year. This number shrinks to approximately 200-300 students who study second year Chemistry. Criticisms by staff about wasted resources in the 'wet' laboratories in light of the standard of educational benefits that these were providing, resulted in studies being carried out that used video cameras to investigate how effectively students were working in introductory practical classes. It was revealed that, on average, students were unproductive in these laboratories for 70% of the time. A plan was then developed to produce IMM tutorials to replace the 'wet' labs.

Nott [4] in his report about this initiative estimated that the cost per student hour of the multimedia presentation was approximately $3.00 compared with $6.00 per hour to provide the 'wet' labs. Cost-effective solutions using IMM technology are only possible if careful analysis of the problem and thorough estimation of the cost have been carried out. Phillips suggests that "...in too many academic projects, few estimates are considered in detail and the grant application process involves only a cursory analysis of a poorly defined problem". Poor feasibility analysis and inadequate estimation of cost carry significant risk for the implementation of IMM tutorials. Phillips estimates that 1 hour of interactive multimedia tutorial takes somewhere between 300-500 person hours to produce. Ineffective planning will cause project development time - and of course costs - to be increased. Nott has estimated that the cost per hour of a traditional lecture to a group of 300 students costs $0.50 per student hour. Before proceeding with IMM development, it is important to investigate whether there are cheaper alternatives and to carefully estimate costs. In addition, the educational purpose of the development must be defined and cheaper alternatives that may achieve this purpose equally as well must be considered.

INNOVATIVE USE OF DELIVERY PLATFORMS FOR NITS:

Diskettes and Internet delivery: In the case of IMM tutorials, choice of delivery platform depends on the educational requirements that have been defined and on the software design itself. Programs that are deliberately kept small (by limiting the use of video and sound for example) make it possible to distribute the software to students on their own floppy diskettes or for the programs to be downloaded to remote sites over the internet should this be required. In the Computer Science Department, we have provided students with the tutorials in the form of mastered executable files that they can take home on 2 floppy diskettes and install on their own systems. We are also able to provide internal access to executable course materials via the internal departmental network and have developed the capability to provide external access to the executable materials via the World Wide Web so that the tutotrials can be run on their home computers.

LAN services: Local Area Networks (LANs) provide opportunities to use inexpensive groupware applications in innovative ways to improve communications-based courses. In Software Engineering courses in Computer Science at RMIT we require students to build larger systems in groups (typically these project groups have 4 members). Software Engineering 1 involves approximately 200 students across 2 campuses (the City and the Bundoora campuses which are approximately 15 km apart and connected by a microwave link). Administration of the assessment of the individuals in these groups has created some challenges.

In the past, we have found it difficult to assess individual's contribution in groups when there has been a lack of commitment by some group members. To address this problem, we have produced an online application which requires students to enter individual diary details on a monthly basis in the first week of every month. Each student from both campuses is required to enter the details of their work in their software engineering project team over the last month. They are also required to describe the contribution of their peers. We also students to make general comments about the progress of the group and the advancement of the project. Students' monthly 'diaries' are then e-mailed to the staff member who has the responsibility of coordinating the project. This has allowed us to gain a practical insight into the workings of the group and to assess the contributions of its individuals. Since implementing this approach, it has become evident that their has been a general improvement in the progress of all the teams and that students have improved their ability, both individually and collectively, to evaluate and to manage their group's processes.

In another initiative to encourage collaborative learning in Software Engineering 1, we have established the requirement that each group maintains all agendas and minutes for group meetings and that these be stored on a central UNIX account. These are required to be accessible to all members of their group as well as to tutors and lecturers. We also provide a newsgroup on a UNIX server, on which students can ask and discuss questions about the project. Using this newsgroup, project managers and lecturers are also able to clarify important details of the project if appropriate.

EDUCATIONAL THEORIES AND IMM DEVELOPMENT

We suggest that a well-designed piece of software should incorporate the most appropriate aspects of 'each learning theory. Effective design for NITs aim to provide cognitive engagement for the learner and must be an integrated extension of existing courses.

Interactivity in IMM tutorials can have a number of meanings. On face value it can simply mean that the user interface is interactive, that the user can click on a button or can make a graphic appear or disappear for example. In effective design for IMM tutorials however, we suggest that designers need to structure the entire design so that students become interactively *engaged* in the learning process itself. This provides a challenge to designers to present the chosen content so that students *learn* rather than get *told.*

Educational processes represent complex activities and these are, difficult. to describe. Educational theorists, use continua to describe the dialectics of concepts and processes that relate to the educational context. We suggest that designers of educational software must consider these and should identify the point in the continua that describe the design or effect of the educational software that they are producing. It is not possible to design effective IMM tutorial implementations without considering the ways in which epistemology - philosophical theories about the existence of knowledge - and pedagogy - the means of presenting knowledge-inform educational theory.

Objectivism suggests that knowledge exists independent of human experience. An objectivist pedagogy assumes that knowledge can be constructed in a logical way and that it can be broken it into small components that have learning objectives associated with them. Objectivism assumes that the learner is an empty vessel that needs filling with knowledge. CBT material that involves drill and practice or that has its major focuses on the answering of Multiple Choice Questions falls in this category. Phillips suggests that this form of CBT may be an appropriate technology to use in training a large number of staff to remember a set of predefined procedures. One of its strengths is its ability to address novice learning and skill development situations. Laurillard [2] argues however that designing presentational to provide component parts of the knowledge, fails to cater explicitly in the design, for synthesis of the knowledge.

We suggest that the learning processes that are a result of the use of IMM tutorials need to be integrated into the complex web of processes that are a result of all of the learning experiences that have been provided in all aspects of a course structure. We have looked at some examples that aim to integrate new kinds of tutorials in tertiary courses. A problem can occur when CBT is seen as a standalone addition to a course because it assumes that the role of the teacher can be replaced by a series of learning objectives. When this is incorporated in a computer program it is logical to assume that the computer itself replaces the teacher. Phillips argues that computers can be used effectively in courses if they are used to *support* the complex process of learning. Use of computers can not replace the quality of dialogue that effective teachers can maintain. We suggest NITs need to be designed so that they can be integrated into courses to complement and be complemented by other course components.

Constructivism on the other hand, suggests that reality is in the mind of the knower and that the knower constructs or interprets a reality from his or her perceptions. An IMM simulation application that imposes no navigational structure on the user and that allows the user full freedom to change factors that affect the environment being simulated and to observe the results is an example of an application that falls in this category. The constructivist viewpoint suggests that although reality exists independently what we know of it is what we construct individually. It is not useful therefore to impose another's perception of the knowledge structure on the learner, rather the learner must be provided with experiences that allow him or her to synthesise an individual perception of the knowledge.

USER CONTROL AND NAVIGATION IN IMM TUTORIALS

In light of these theories, designers must give consideration to matching the intended content matter, with the learners needs and with planning of the degree to which users will be given control over the navigational structure through the body of knowledge. Whether to use a linear, hierarchical or mixture of these will depend on the degree of responsibility that is to be placed on the users and on whether the content lends itself to elicitation in steps (for example a mathematical derivation) or conceptual treatment in the broad (for example the effects of market forces on national economies).

FEASIBILITY ANALYSIS

As the requirements are being analysed it is of critical importance to examine the feasibility of the project by identifying alternative solutions, estimating project costs and expected development time, and investigating available hardware and software for development and delivery. It is also necessary to decide WHY an implementation of a NIT solution will be appropriate for the defined problem and to investigate whether anybody else has done a similar project before.

SOFTWARE ENGINEERING

A Requirements Specification must clearly define the required functionality and scope of the project including an overview of the project structure and an overview of the content that is to be covered. Ideally, it should contain details about high level navigational strategies that will be used to move through the content, the design of the user interface and guidelines about graphics design. A storyboarding approach should be used to begin developing the content by deciding about what content will be on what screen. Simple storyboards can be created with pieces of paper on a wall, linked by pieces of string to model the navigation.

The software methodology that we have found to be most appropriate for development of IMM tutorials is that of incremental prototyping in which paper prototyping is employed. Irrespective of the development phase (or development task) that is being undertaken - Requirements Analysis and Definition, Feasibility Analysis, System and Software Design, Implementation and Unit Testing, System Testing - this approach comprises iteration from design to formative evaluation back to design and so on. As iteration of all phases and tasks continues, it is recommended that authoring should not start until a comprehensive specification of the program has been produced (including screen 'shots', navigation structure, content design, graphic design etc.) . This can be done either on paper or electronically. This will improve the quality of the final product and will minimise the risks of the projects running over time and/or over budget.

CONCLUSION

Analysis, design and implementation of IMM learning environments require an understanding of learning theory, human factors and systems and software engineering. The diversity of opportunities provided by rapidly developing technologies makes important design issues more complex. So that implementations of NITs improve the effectiveness of educational environments, we suggest that an understanding of these diverse areas and adoption of sound software engineering practice are important.

Effectiveness of NITs is concerned with considerations of their cost effectiveness as well as their ability to deliver learning experiences of quality. It has been shown that development of IMM tutorials is costly although if student numbers are large they can be cost-effective. Quantifying the potential of NITs to produce better educational experiences for students is a little harder. This along with development of a taxonomy of design features is a crucial area for future research.

DISTANCE EDUCATION: STANDARDS OF COMPUTER LITERACY

D.A. Bogdanova (Russia)

The past three or four years have witnessed an avalanche-like growth of interest in the various kinds of distance training. And this is only natural: in our vast country with its backward infrastructure and significant concentration of scientific research and educational centers, an opportunity to get an education while continuing on one's main job is extremely valuable. It is also obvious that the operating system of correspondence education is failing to meet the growing demand.

This presentation deals with distance education on the basis of text computer conferences. In the West, where telecommunications are advancing at a faster pace than in Russia, on-line computer conferences have already become one of the distance education methods. A computer conference provides opportunities for organizing the students' collaboration and applying the methods of business role play and brainstorms. All this becomes possible by conducting virtual classes on the basis of computer conferences - a technology that is certain to find a vast number of applications in education in Russia.

There exist many types of computer conference differing in the mode of interaction with the computer or user interface, as well as in the arrangement of computer conference subjects. However, all of them have the same structure. A conference opens with a text that sets its subject. Each participant is then given a chance to add a comment of his/her own. The comments are arranged consecutively as they arrive and are accessible to all the participants, as is the primary text. Each participant works at the time that suits him/her best, but as the discussion progresses, the text incorporating the later comments begins to more closely resemble a stenographic report of any ordinary conference. The moderator has an opportunity to shape the primary text, to analyze the contribution of each participant, to amend a participant's text or to encourage a person to «say» more.

The participants may be divided into groups to develop some subject or another, their access to certain subject may be restricted. Generally speaking, the opportunities for organizing the educational process are broad. This is a good place to discuss the off-line conferences, which are more common in this country. The thing is that in this case, there exists a certain time lag (hours and even days) between the dispatch of a comment and its placement in the computer conference, as well as between getting information from the computer conference and actual access to this information on one's PC. This is why the dispatched comment may become obsolete, prove a repetition, be out of place because the discussion has taken a different turn, etc. Another fault of the off-line computer conference is that it is impossible to choose new material for read-off. In an on-line conference each of its participants has a chance to scan its contents and decide what he/she wants and get only the required information through his/her computer. The participants of an off-line conference do not know what new material is available and are obliged to order everything. The more intensive the work, the worse the off-line computer conferences are.

The success of computer conferences largely depends on the host, the moderator. The latter organizes and conducts the conference staying with the participants from beginning to end.

For all the merits of computer conferences as a means of distance training, there exists a number restrictions on the scope of their use. One of them is that the students' skills of work in telecommunication networks are not always up to the required standard. This happens mainly because the current school course of informatics does practically nothing to prepare the students for this form of work. The computer literacy level obtained through this course does not usually exceed the skills necessary to use an isolated computer, the students have very little idea of computer networks potential.

The concept of *computer literacy* was shaped when it became obvious that the. computer was ceasing to be a narrowly specialized appliance and was coming into mass-scale use. The substance of this concept changes with the expansion of the sphere of application of information technologies, and meets society's needs for their application at each development stage of this process. At the initial stages, the concept of computer literacy was based on Academician A.t. Yersnovs well-Known saying:

«Programming is alter ego of literacy». Later, computer literacy came to be interpreted as an «information technology» of problem-solving. Further development of information technologies as regards their impact not only on the technological aspects of civilization but also, increasingly, upon the cultural ones has produced a new interpretation of the concept of computer literacy. At present, its most apt definition is *information culture*. Apart from the other aspects of the use of information technologies, the concept of information culture implies having the skills required for work in telecommunication networks. This change has been reflected in *Information Culture,* the 11-year informatics secondary-school course edited by Yu.A.Pervin. Nevertheless, even this most recent course does not specifically expand the concept of computer literacy by including telecommunication components into it.

To work well in a computer conference, the following elements of computer literacy are required:

- skills in the use of a text editor;
- a good idea of global computer networks;
- ability to use a telecommunication program;
- ability to use the computer conference software;
- skills in the search for information in the networks;
- an idea of information protection and its legal status.

A COMPUTER CONFERENCE PARTICIPANT ALSO REQUIRES THESE SKILLS TO BE ABLE TO:

- read new messages and answers;
- read previously received messages and new comments on them;
- add comments to the existing messages or place new messages in the conference;
- send personal messages.

THESE ELEMENTS THE CONCEPT OF COMPUTER LITERACY AND AT THE SAME TIME CONSTITUTE A NECESSARY CONDITION OF WORK IN COMPUTER CONFERENCES

Computer literacy is acquired in informatics classes. On the other hand, according to the Russian general educational informatics standard, it is a general skill which can and should be developed in the process of learning any subject. This is why there are two ways of expanding the concept of computer literacy by including elements of network technologies into it:

- in informatics classes;
- while learning other subjects using the computer.

What is more, the network elements of computer literacy can be taught in the course of practical work in computer conferences regardless of the latter's subject. Needless to say, the formation of these elements does not happen automatically but should be directed by a moderator, who encourages further training and turns it into the proper channels. This approach was used as the basis of the methodology for the formation of new elements of computer literacy in the course of computer conferences.

The main principle underlying this methodology is that the required level of computer literacy is achieved by students teaching each other. This approach rests on the fact that a certain section of computer conference participants is better trained than the rest and can transfer knowledge and practical skills to the less advanced ones. The substance of the method is as follows:

- work begins a month before the conference is scheduled to open;
- the students get brief instructions on how to link to the computer conference and work in it;
- two parallel conferences open:
- the *first* is the training ground where the training conference on the preset subject, for example, PCs, takes place;
- the *second* is the so-called virtual cafe, where the students can discuss any subject not connected with the subject of the training conference. This is the place where they mix, consult each other, ask for help, get it, etc.

The purposes of these conferences are:

- to identify the students with a knowledge of telecommunications;
- to ascertain their readiness to share what they know with others;
- to organize mutual training and ensure the computer literacy level sufficient for beginning adequate training within the framework of the computer conference.

Here are a few possible questions:

- What do you know about FIDONET?
- Can a private message be sent to any participant without quitting the computer conference?
- Is it possible to send information from your computer to a friend's computer using the modem but bypassing the telecommunication network?
- Do you like to have people for a birthday party?
- Do you like giving presents?
- What do you find more interesting, to play chess with a computer or with a boy/girl your age in Great Britain?

Work in both conferences was monitored by the moderator. The experiment went on for three years in several Moscow schools; its results were measured and qualitatively evaluated.

The following measurement techniques were used:

- The statistical method

The computer conference automatically provided statistics on the users' work. In this way, the students' performance was analyzed throughout the entire conference: the ratio of the students' messages to teachers; identification of the key messages, which collected the largest number of comments and caused the highest number of chained interactions; the number of communications a day for a measured period, and many other things.

- The polling technique

The preliminary questionnaires distributed among the students before the outset of the training course assessed their expectations. The final questionnaires emphasized new knowledge and skills acquired as a result of the training.

- The interview method

A number of students accustomed to team work met in a certain place; the survey had the form of discussion.

- Contents analysis

For the purpose of this analysis, the following questions had to be answered:

- Do the students draw on the previous messages?
- Do they draw on their own experience?
- Do they use the conference training materials?
- Do they use suitable material outside the conference* framework?
- Do they generate new ideas for discussion?

An attempt was also made to measure the expansion of the content of computer literacy. After five – eight sessions, the students were offered three-level tests (V.P. Bespalko's method), e.g.:

- *Level one:* To work in a telecommunication network, one needs a computer, a modem, a telephone line, a telephone, special software, a network address (choose the requisite).
- *Level two:* Why does a telecommunication program request your name and code at entry? Can information be stolen? What does the moderator's starting message say in the *«Café»* conference? etc.
- *Level three:* Send a brief message to all the conference participants. What units can be used to evaluate the information?
- As a result of purposeful training directed by the moderator, the required level was achieved after eight - ten sessions; this level was later consolidated by work in a computer conference.
- On the whole, the results of the experiment confirmed that the developed method makes its possible to achieve an adequate level of computer literacy in a computer conference environment thus ensuring the students' subsequent efficient performance in computer conferences.

SOME PROBLEMS OF DEVELOPMENT OF UNITED INFORMATION SPACES IN EDUCATION ON THE BASIS OF THE PRESENT AND FUTURE TELECOMMUNICATION TECHNOLOGIES

Sh. Sh. Chipashvili (Russia)

1. STRATEGIC TARGET OF INFORMATION TECHNOLOGIES DEVELOPMENT IMPLEMENTATION

For improving efficiency of development and implementation of modem and perspective information technologies it is necessary to define more precisely a strategic objective for the society of this really revolutionary stage of our civilization history.

Beforehand it is reasonable to present more clearly what exactly in the most degree contributed to speedup developments of mankind as a whole, to raise the level in all spheres (spiritual, corporal, professional, cultural etc).

In the opinion of the author, the most efficient in the progress of any society it is expansion of the united information space, simplification of procedures to contact with this space, simplification of procedures to access to information for any society member.

In all those cases the creation of united information spaces has had and will have more important value for society progress than even the creation of united material spaces. For the development of the last one is sharply accelerated due to mutual knowledge exchange and effort concentration for further cognition of the universe, development of science, technologies and culture.

Therefore it is possible to consider, that strategic target of introducing the information technologies in all spheres of human activity still is the necessity of creation of united information spaces on the bases of principally new possibilities offered by these technologies.

It is known that these information spaces can be of three levels (each level falls into the next one as a sub domain):

- local information spaces (departments, institutions, enterprises, organizations and alike);
- regional information spaces (territory, country, group of countries and alike);
- united world information space.

Hens we come to the conclusion, that the main role belongs to telecommunication information technologies. For only they will allow any user to communicate with the united information space, in the interactive mode, rather than be a simple silent consumes of imposed information.

Hence also it appears that we have to use a united coding of the semantic features of information for ensuring to all users of its semantic adequacy on any national and ethnic level.

Accepting an idea of the united information spaces creation, as the main strategic target, will allow to plan more purposefully the processes of implementation of modern and perspective information technologies in all scopes of mankind activity, and with more optimum to take into account all national and international aspects of these important for terrestrial civilization of processes.

In the process of introducing new information technologies in different spheres of social activity it happens to face the same problems and difficulties, as for other new innovation means and technologies.

The history of our civilization development gives the evidence that new means and technologies, which are the results of scientific and technical progress, and they are primary for the further development of the society. Then follows investigation of ways of their use for the society. As a conclusion to this process are searching and implementation of the necessity organization forms.

The last two above mentioned parts, composing the progress, very little depend directly on creators of means and technologies. In general, they are defined by needs and possibilities of the society, in economic, ideological and political situations, by conditions of international co-operation.

It is natural, that a certain degree of conservatism (in some cases is, by the way, necessary and reasonable) in organization forms ways of using of old means and technologies, not only does not promote, but counteracts a process of implementation of new means and technologies.

All this is also lawful for information technologies especially in the case of telecommunications. There are given bellow three problems, which will really of optimal use of modern and perspective telecommunication and information technologies in sphere of education.

Therefore it is possible to suppose, that the decision of bellow given problems, in one or another degree will raise efficiency of using the information technologies in the first place and namely in the scope of education.

2.PROBLEM OF ARRANGEMENT OF UNITED, AND LOCAL CENTRES FOR FUNDAMENTAL KNOWLEDGE

The volume of current knowledge (particularly in the field of exact sciences) is international in itself. It is possible to speak about the contribution of scientists of different nationality or citizenship in the level of cognition of one or another field of science. Hut to speak about the national mathematics, physics, chemistry and so on, it is hardly legitimate.

Telecommunication and information technologies, unlike the so called "paper informatics", do not impose strict restrictions regarding the depository location, or information source, or access time to it.

Therefore for these technologies it is reasonable to start creating new methodologies of international and regional accumulation of current source of fundamental knowledge in various brunches of sciences for different education levels.

One of the possible directions of solving this problem is shown below.

a. United International Centre for Fundamental Knowledge (UICFK) is created for each chosen field of science (or subject of studying). The creation of UICFK must be done not so much by pedagogical but by scientific structures. Therefore information contents of UICPK (as a large standardized information base) must be formed by the international group of scientific institutions, authoritative in the given field of science.

Out of this group the main institute Is nominated, where UICFK is being formed as an international information-reference centre for collective (common) use with subscribers tele-access. As the cognition in the chosen branch of science is developing, the constant renewing and correction of the information contents in UICFK have being done.

Simultaneously the volume of knowledge in the certain branch of science can be indicated and recommended for each education level.

This Centre should have only accumulated by the mankind concrete knowledge of certain subjects. There should not be any method of teaching of the subject in UICFK.

b. In regions (continent, group of states, greater state) it is reasonable to form Regional Centres of Complex Fundamental Knowledge (RCCFK). These centres, as complex information bases, should contain fundamental knowledge of different branches of mankind knowledge. Necessary information for given centres will be obtained from the corresponding UICFK through tele-access.

As RCCFK will be oriented on problems of education in the given region, so besides fundamental knowledge of different subjects, there should be method and recommendations for teaching of given subjects.

In itself RCCFK will be centres of collective (common) use with tele-access for educational institutions, scholastic groups and independent learners of the given region. Therefore creation of RCCFK is reasonable to make under the aegis of the department, supervising education in the given region.

c. Right in educational institutes it is reasonable to create Local Centres of Fundamental Knowledge (LCFK). These centres, as information bases for concrete educational institutes of different levels, should ensure full information and methodological support of school plans of the given educational institute.

LCFK connected trough tele-access to RCCFK (and in some cases to UICFK) will have the possibility not only to track all the changes, but will provide quick possibilities for studying practically any new subject.

In itself LCFK will be centres of collective (common) use for students (or school-children) of the given institute (school), for all external students and self-training ones. It will be as well as object-translator for user entry to RCCFK and even to UICFK .

3.PROBLEM OF UNITED SEMANTIC CODING

As UICFK should satisfy the needs of the whole mankind and be available for all folk regardless of ones nationality, immediately the problem of semantic understanding for a carrier of any national language arises.

Every body knows out of ones own experience, that there are not appear problems in International communication, if the main subjects of communicated information are graphics or images. In these cases there are no needs of international transformations of information. More so, the volume of such sort of information is overwhelming (more than 96 % of the whole information, consuming by mankind). And there is also no problems of international music perception in the world communication.

And only in the written languages and speech, though forming rather small volume of the consuming information (but at the same time very important one), there appear all known complications in international language communication.

Of course, modern information technologies (but perspective - more so) allow to perform necessary direct translations from one national language to another, even in the dynamic mode, regardless of technical resources spent.

But there are two essential difficulties there.

Firstly, there must be very great amount of acting automatic translators there. For instance, if it is necessary to organize a direct communication between carriers of ***N*** different languages, the quantity of automatic translators ***T*** must be equal to ***N (N-1)***. For instance, if we put the limit, let us say, of 100 languages of the main countries (without small languages and dialects), it will be necessary to have about 10 thousand automatic translators.

Secondly, none of the speed and tricks used in information processing will allow to achieve the desired degree of adequacy in international language translation. This is counteracted by the essence of process of development and construction of any alive (or dead) natural national language. So a database (knowledge) on any national language can not be adequately transformed into the identical database (knowledge) on another national language.

If we take any language as a go-between for the international communication, there are possible two way here.

The First out of them is to consider this language as an auxiliary second language, and using it to realize all processes of cognition of nature, of technology development, education and for any professional communication. But, as a rule, without transition to the national languages (and if would means here will be no need for translations).

There are many examples of that kind. The most known example of similar approach is Latin, which has been used for almost 12 centuries as the common language for science, technologies and education. In medicine, up till now, physicians of the whole world are in the united information space by means of Latin.

The second way is to consider this auxiliary language as only an internal go-between language for technical systems and devices. Then communication of carriers of different national languages between them only through technical facilities, changes greatly a situation with the quantity of necessary automatic translators. By this for ***N*** languages there should be only ***2N*** of ***T***. Therefore in the example with 100 languages there would be needed only 200 translators.

However, for the last case, when using any natural national language as an auxiliary technical go-between language, there are completely saved difficulties with inadequacy of international language translations.

In the science and technologies similar difficulties are easily overcome by implementation of intermediate strictly determinate coding. This allows to produce a transition from one marking system to another without the loss of concrete essence of semantic system.

In this instance, when we speak about necessity of semantic adequacy while making the translation from one national system of writing to another, it is necessary to have an international, artificial, auxiliary, go-between language (which can be used also as the second language).

Consequently, it is required here participation of professional linguists and philologists rather than simple solving the task of semantic coding by technical specialists.

If this international, artificial, go-between language will possess such interlinguistical characteristics, as possibility to plan, aposteriority, autonomy and neutrality, then this language will be the most optimum one for using in technical systems, particularly in international telecommunication systems.

If it is possible adequately, according to semantics to perform a transition from any national language into information space of similar to the auxiliary, go-between language, then it will be possible to provide the same semantic adequacy to make a transition back into any other national language.

At present, there are rather many artificial languages in the world. For instance, specified above mentioned requirements, to a certain extent, are met by enough developed and already broadly used the international artificial language Esperanto.

Less than two dozens of grammar rules, not allowing any exclusions from them; monosemantic process of "how one writes, so one hears; how one hears, so one writes"; intelligibility and clearness of word formation (including new words) and many other merits make Esperanto sufficiently attractive for using it in technical systems of informatic while making the united information spaces.

However the last word should be after linguists and philologists.

4. PROBLEM OF CHANNELS AND DATA COMMUNICATION SYSTEM

There is only one side of great interest in this problem of education: cost of traffic and tariffs.

Implementation the telecommunication information technologies in the scope of education will, in the first place, depend on possibilities of getting the data communication system services. And this will depend not on technical facilities, but on pure financial ones.

The way of creation of special data communications systems and channel networks on any level hardly has real prospects. Cost of them will exceed all expenses of direct process of education. This equals to plan laying railway or telephone network specially for students or schoolchildren only, to the account of education.

Therefore social policy of any country (or group of countries) must stipulate the obligations that all data communications system owners and owners of telecommunications will concede part of their facilities for education purposes using very low tariffs, or free of charge at all, or on the account of states and international organizations.

5. CONCLUSIONS AND PROPOSALS

1. Experience of introducing the telecommunication information technologies in different areas of human activity shows that for getting appreciable efficiency from given technologies it is reasonable beforehand to begin from structural and methodological changes in the processes of accumulation and distribution of information.
2. Creation for the scope of education standardized information centres of common use, such as:
   a. United International Centres of Fundamental *Knowledges;*
   b. Regional Centres of Complex Fundamental Knowledges;
   c. Local Centres Fundamental Knowledges, that will allow using the telecommunication information technologies to start a process of shaping the united world information space for the scope of education.
3. Implementation the united auxiliary, artificial, go-between language will allow to use with maximum efficiency telecommunication technologies with the aim of creation of the united international information space for the scope of education.
4. The most favoured policy conducted by states and international organizations with regard to reducing the costs of data communications system services for education will make the implementation the telecommunication information technologies into the scope of education a more dynamic and available process.
5. The specified problems can be successfully and complex solved only under the general organizing and methodological aegis of UNESCO.

PROPOSAL FOR FINAL RECOMMENDATIONS OF CONGRESS

1. For development and organization of further constant work for solving the problem of the united international coding of semantic part of information (the problem of united, artificial, go-between language),

recommend:

- to create under the aegis of UNESCO international organization (commission, centre, etc.) with the financing by the main states-participants for realization of the Project "INTERSEMANTICS";
- to ask the Russia representatives, as initiators, for emerging co-ordinators of this Project.

2. Recommend to the states-members of UNESCO to reach agreement on legislative fastening their own countries the obligation to grant the facilities and the services of the state and commercial telecommunication networks for the scope of education on the free of charge or favourable bases.

EDUCATIONAL NEW INFORMATION TECHNOLOGIES: ELIMINATION OF DEFECTS

A.L. Gorbunov (Russia)

Today all new information technologies (NIT) have either telecommunication component or a sort of projection into computer communications. Therefore, a key point for our discussion is the ways for overcoming negative aspects of snowballing process of Internet service penetration into educational NIT applications.

First of all, here are some more or less fresh facts. On February 8, 1996, USA president W. Clinton signed the law, providing the penalty up to $250,000 and 2 years of the imprisonment for granting minors the possibility for telecommunication access to the materials, containing pornography and violence propagation. In March B. Gheits has published an article on the problem of censorship necessity in Internet. In April judicial bodies of German Baaden-Wurtemberg province started investigation on the fact of distribution of the ideas of neo-nazism and anti-Semitism through WWW by neo-nazis.

The above mentioned facts unequivocally testify the phenomenon of crisis of western civilization, designated yet by Heidegger who wrote about the conflict between civilization and culture. At present, the crisis begin to expand from purely theoretical sphere into a completely practical area of. NIT implementation.

Here, crisis phenomena result from the effect of technological pollution of thinking (ETPT). ETPT is such a negative consequence of the rapid technical progress, as more habitual «pollution of an environment by industrial wastes». ETPT is, in a way, a mental «analogue» of the environmental pollution.

ETPT is displayed as involuntary using of purely technological definitions, interpreting methods and problems solving approaches which are suitable practically for any kind of activity. The most evident example of ETPT symptoms is a mass culture of western type, all phenomena of which have hypertrophied technological character and in particular the computer games, created for training purposes can be considered as an example of ETPT through NIT in education. Loud design and various multimedia effects, fabulous plot grasp attention of the children providing them with a certain information, arranged in the appealing way. But a primitive principle of dual oppositions, which is a basis of scenario organization for any computer game, imposes on thinking of the children specific «machine» print. And very soon and quite distinctly this «machine» element is becoming a prevalent one in the intelligent tools arsenal of the children.

Another evident and forthcoming danger is an expansion of the virtual reality systems, with the numerous applications fallen within educational sphere. Here contact between the person and the computer has been greatly extended and the computer begins absorbing person, to merge with it and person does not always play a leading role in this new unprecedented phenomenon. It brings to the extreme mechanised way of thinking and total absence of moral settings, as the computers have not moral values (last film-festival in Toronto, occured under «sign of virtual reality» was rather significant in this sense).

ETPT is especially dangerous today's Russia going through the times of social and economic «tectonic» transformations. Borders between truth and delusion; useful and harmful, science and non-science are hardly noticeable under these conditions.

And yet situation in Russia originated from the compelled 80's hermetic isolation and preserving in a paradoxical way has certain positive sides. In particular, there is an opportunity of comparatively fresh and sober approach to things, which is free from «consumption society» prejudices which is natural for public consciousness for the countries with advanced market economy and its orientation on priorities of direct economic efficiency, the principles that already revealed negative moral and ecological consequences of their dominating. Besides we have an advantage (though, not long duration one) which is concluded in the absence of mass ETPT.

We may try to use temporary profits of our situation. The true is always banal, therefore we apply standard technique, which is usually called «creative re-consideration of the accumulated experience». In this case we shall take into account other's mistakes, i.e. we'll reconsider mainly not ours' but western negative experience, though not without our own approbation. The result of such procedures is an understanding of a place and role, which NIT may bring into education, with cutting out all the negative consequences of technological dominating.

It is supposed, that such understanding will supply methodological transition from non-systematic use of NIT for solving certain local problems at teaching to the complex «implantation» of NIT into the substance of educational process. That allows to use these technologies, on the one hand, accordingly to their potential, and on the other hand to place them inside «educational living structure», without breaking usual coordinations and functions of the «body» already being available. To realize this program it is first of all necessary to have a clear understanding of this «implanted» body function.

Though it may seem surprised but this idea is practically impossible to find among a great number of articles and sayings on the NIT subject which is probably connected with the extremely high rates of information technologies development and as a result of the fact specialists' thinking process is far behind dynamic reality.

So, NIT is first of all the computer. Computer is a machine. Machine, as is known is an amplifier of person's capabilities. This is the way of using computer facilities which is practised in the majority of cases. However computer is far from simple machine but machine with elements of self-organizing and rudiments of intelligence, though in most primitive form. Therefore in case of including it in the educational process as a simple amplifier of some ability like making calculations or for working a bulky, but not too complex problem (say, connected with processing of big information volumes with using vast resources of Inernet), computer starts «to push the teacher out» from the educational process, simultaneously imposing to the pupil its own, computer logic of defining and solving problems, which, despite computer quasi-intelligence, has purely machine character.

So we can make a conclusion that in the general educational applications intelligent complexity of the problem solved with using NIT should not only meet NIT capabilities, but to surpass them. That supplies a space for self-realization as of both the teacher and the pupil. Thus, function NIT in educational process can be defined as a help in solving of rather scale educational problems, «screening» a persuasive effect of technologies as such. The educational NIT should be a «transparent» and universal instrument, making its introduction in advanced educational procedures pertinent and expedient.

Thus we do not mean elementary utility of the application, for example, creating of big texts with the help of the computer is the operation as obvious as driving nails with a hammer.

Among the educational computer tools, bearing the mentioned above qualities, the teaching multimedia from a series «Computer EGO», in our opinion, should be noticed. The author uses these products at working with the students of younger school age for the last four years. Everyone knows the children's designers LEGO. Everyone knows children's programming language LOGO. In the middle of 80's professor Seymour Papert offered lucky idea to join these two products for children that are popular and differ by their nature with the purpose of creation of unified educational medium. This idea was implemented by the research group of the Massachusettes Technological Institute, which was personally leaded by professor Papert.

Practically the idea was realized as a kind of medium. «Computer LEGO» is a designer of LEGO company, extended by electronic components (various gauges and executive bodies) and software, allowing to create LEGO-objects controlled by the computors, capable to co-operate with external environment.

As an example of practical application of the «transparent NIT» concept we can mention the project on creating telecommunication language for LEGO-objects description.

A demand for such language was developed quite naturally. Following the publications devoted to the Computer LEGO the electronic mail started to bring to the author the responses from various countries of wide geographical range. Basically, these were teachers' requests to inform them of ideas of the projects. The question has immediately arisen of how to make it in use by means of the electronic communications. Verbal descriptions of LEGO-constructions are very bulky and, taking into account double language barriers, are fraught with the large distortions. The best way of the LEGO-constructions designing is three-dimension graphic images, but the graphic files have very large sizes, that makes their transfer through Internet and other computer networks unreliable and expensive. Hence, this regular topology of basic LEGO elements causes rather simple structure of such language. The above fact is an additional circumstance, allowing to involve the children of 9-10 years as quite competent developers. This is the language that is being developed now. The interpreter of the first, two-dimension LLL version is already created. (Our so called tele-philological product was named LLL). Computer technologies, which, one should think, make core of the given project, actually present only an opportunity to understand beauty of natural languages or their construction. The children have independently developed morphology and syntax LLL, mechanical and the programme modules of the interpreter LLL, check results of the work in network sessions of exchange by the LLL-offers. Thus, the mastered computer and telecommunication specificity (should be emphasised - at the most advanced level) is nothing more that background, «transparent» activity, but «normal» communication properties of language remain at the foreground. It was not just coincidence that this project has attracted the attention of young girls, who do not usually participate willingly enough in the activity of engineering mode.

It is obvious, that «transparent» NIT is a concept, directed not so much on purchase of a complex of knowledge, abilities and skills, but on development of the creative and intelligent approach as to a problem of application NIT, and to today's education as a whole.

What it is necessary for realization of the «transparent» NIT concept? First and foremost, it is the staff, which is the basis for all the success. The •programmes for training and professional level improvement for teachers of any speciality should include a «NIT» course, within the framework of which:

1. A contemporary situation in NIT field is the most dynamic and constantly updated part of a part of the programme representing current and promising development and tendencies, possessing educational significance.
2. The criteria are created with purpose of meeting educational challenges which can be settled through NIT. This section is a key one. The correct formulation of an educational problem is the basis for efficient NIT application and final success. The basic parameters are as follows: contents of a problem and its configuration that are adequate to features of NIT tools, attractiveness for the students.
3. The criteria are created in purpose of selection of specific tools from NIT arsenal with purpose of meeting educational challenges. The basic parameters are as follows: possibility for covering with the tools of wide range of concepts and subjects, easiness of comprehension by the students. These parameters

are usually strictly correlated. In most cases advanced NIT tools do not require mastering by the teachers. It seems to be a standard situation when the students during work are learning the tools much better than a teacher.

4. The practical skills are acquired by the students by means of the most universal NIT tools, allowing for the application to educational practice in any area.
5. NIT implementation into educational process is the imperative of these days. Natural difficulties of growth cannot be the reason for NIT rejecting. However, the practice of direct copying of someone's errors is also ridiculous. This practice is sometimes displayed in an unfounded implementation of high technology components in educational process. It is obvious, that NIT implementation into training should be considered in a context of dominating of classical, being improved through centuries pedagogic, which is based upon long living criteria. But the selection of new technological tools should be very verified, extremely careful and cautious, as it is meant by the concept of «transparent NIT».

IMPLEMENTATION OF ACHIEVEMENTS IN INFORMATICS IN TEACHING TECHNOLOGY OF THE MODERN HUMANITARIAN UNIVERSITY

M. P. Karpenko (Russia)

The Modern Humanitarian University (MHU) uses original training technology, aimed at the stimulation student's *self-study work*, increase in efficiency (speed of new knowledge mastering), time saving for the students: number of class hours per week equals to 14-17. Principle of knowledge splitting and dozing is implemented. With this purpose, all the material studied is divided into primary educational cycles within each educational field.

Each cycle has standard structure (and technology of educational processes) and consists of several stages.

The first stage is *self-study* of information materials by the student from database of MHU.

The second stage comprises video-lecture in video classes up to 30 persons.

The third stage is an active practical class as business or operation games, roundtable, discussion and etc. Students' activity is accounted during certifying.

The fourth stage is computer classes as such.

The training computer programmes are developed by University specialists themselves. The programmes provide feedback with the students and represent new continuously updated information in dynamics as the contrast to the conventional textbooks. This results in significant increase of training speed. Educational training are conducted on accounting, finance, production arrangement, statistical data processing, editing, translating on the basis of professional programmes. In the course of stock market and finance studying, computer games with the robot, network team and individual games are practised by students.

The fifth stage comprises accomplishing ofcreative home tasks in the form of the logically organized knowledge database, its classification and professional dictionary creating. This is carried out by students separately for each cycle.

The sixth stage includes testing procedures. The original system for controlling students' learning progress practised in the University includes testing procedures for each part of educational field, evaluation of the creative home tasks, and course designs, written examinations and tests.

The educational centre was established at MHU with the purpose of educational materials development. The staff of the above centre consists of a number of experts, researchers and lecturers. The experts work not only in Moscow, but also abroad. MHU performs 4-year programme for bachelor training on the following directions: jurisprudence, economics, management, linguistics (foreign languages). Thus annually 24-30 cycles are carried out for each of direction. The system implementation required educational products development for almost four hundred cycles. Educational products are constantly updated and are adjusted.

The students are involved into the process of educational products elaboration in MHU. In the course of practical study the students take an opportunity of working at research laboratories and in expert groups elaborating educational materials and computer programmes. In the University, the cognitive psychology and methods for increase of educational processes efficiency are developed. New high technology and distance learning methods, educational materials and products are created in every direction. Social and psychological research is carried out.

Achievements of computer science in the field of educational technology allowed MHU to perform innovative educational process. First, this resulted in improvement of activity of the students and increase knowledge mastering. During business games and discussions the students not only receive the knowledge but also learn to use them in practice in real production situations. In the second place, distance learning allows to University to establish the branches in large and medium cities of Russia and CIS countries.

This gives an opportunity for organising of advanced, genuine high quality educational process in medium and small cities of Russia, where local lecturers staff can provide only practical training and consulting. In the third place, modern copying technology of educational products and standardised methods for learning result in reducing payment and makes chargeable higher education accessible for middle classes.

LINGUISTIC PROBLEMS OF SHARED INFORMATION ENVIRONMENTS

I.I. Khaleyeva (Russia)

The question of possibility and necessity of creating a common subnational semantic code has quite a long history. The idea of an artificial language had a great appeal for prominent philosophers, logicians and mathematicians, on the one hand, and distinguished linguists, on the other. Of the former, it would be enough to name Gottfried Wilhelm Leibniz (1646-1716) and Ludwig Wittgenstein (1889-1951), and of the latter - Yuri Apresyan and Anna Verbitskaya. Our time has shifted the problem from the purely academic plane to a specifically practical plane. Moreover, its solution could be regarded as a vital requirement or - even - the dictate of the time.

There are several reasons to this, of which the two cardinal ones are determined by serious linguistic aspects. The first one is the problem of scope: the information environments are increasingly loaded by texts in various natural languages, and therefore their effective use is going beyond the domain of ordinary "human" technologies. No number of translators can cope with the floods of texts overflowing mankind. The computer solution is automated translation of textual information into a computer language. The second problem lies in the fact that the already existing computer information systems and those under way have reached the numbers that require an enormous effort specifically for their conjugation. It is a problem of *compatibility,* primarily of the local artificial computer languages, the number of which has several times exceeded that of the natural languages (which are estimated, as we know, at two to seven thousand). Thus, we have a great variety of natural languages combined with an extraordinary number of artificial languages.

The arising practical linguistic problems refer primarily to the competence of such explosively developing area as linguistic semantics. Viewed from this point, any artificial language should in the final count (or, maybe, initially) be approached as a specific semantic meta-language, in other words, as a structure secondary to the natural language designed to bring out the intrinsic meanings of the linguistic expressions, spoken or written (depending on a practical requirement, so to speak). From this it follows that the strategy of work to produce a semantic code should have the foundation of the semantic typology of the natural languages, presupposing their semantic comparison for the purpose of identifying the universal mechanisms of linguistic meaning, common to the national languages. It is noteworthy that the problem was approached from exactly this angle, as early as 1969, by B.Y. Gorodetsky (now professor of the Moscow State Linguistic University and Chair of Linguistic Semantics) in his book *To the Problem of Semantic Typology.*

The special part played by the science of language in the solution of these problems is not the result of the linguists' ambitions. The present stage in the advance of the computer revolution is based, in the first place, on the methodology of the artificial intelligence, which, in turn, builds its methodological basis of the ideas gleaned from those fundamental sciences which can 'give a constructive understanding of man's cognitive activity and its product, that is, knowledge.

The methodological role of linguistics follows from the experience of intellectual systems design accumulated at the world level, and, apart from that, from the fact that a natural language is an objectively existing cognitive system which is universal in relation to any artificial language. It is inseparable from human intellect, is the foundation of mankind's knowledge in all the areas of science and technology, a medium of intellectual interaction in space, and time. By its very nature, language is the most constructive phenomenon that has ever occurred in the intellectual and cultural world, and, in fact, all the artificial languages that people create for human or computer applications can be brought down to the natural language. It is logical, therefore, that other sciences within the *Artificial Intelligence* have been actively drawing on linguistic ideas and methods. All the more so, since, nowadays, language is understood as the mode of organisation, presentation and development of knowledge rather than the medium of expressing thoughts. A clear and expletive description of the linguistic ideas "growing into" the new information technologies is found, for example, in the series "New Trends in Foreign Linguistics", volumes XII and XXIV, edited by Gorodetsky, who is also the author of the introductory articles.

As realists, we should build the unity of informational systems upon the integration and development concepts, and not on the totalitarian principles. We can create the core of a universal semantic code and provide for building up upon it, its modernisation, etc., while this should not reject the presence in the informational networks of natioinal-specific components served by the automated translation systems. All this is possible subject to proper scientific examination. Thus, the main trends in the development of linguistic support of the shared informational environment should comprise:

- development of *semantic typology of* the natural and similar aimed at modelling the universal and specific components of the cognitive language systems;
- development of *computer resources of the European languages* (all world languages in future), with the accent placed on computer lexicography, aimed, in part, at building up and maintaining terminological data banks, which are, in a way computer sublanguages.

REFERENCE BOOK FOR DESIGNERS OF COMPUTER TECHNOLOGIES OF TEACHING

S.I. Kuznetsov (Russia)

The «Reference book» is developed for maintenance of educational process at departments of teachers qualification increase and for the students of pedagogical higher schools on special course "Computer teaching technologies". The course is designed for 20 hours of lectures, 20 hours of practice in a computer class and development of course work concerning creation of a fragment of a training computer means for teaching. The reference book contains the necessary data for practical acquaintance with various parties of management process of trainee's cognition activity and gives a technique for the development of computer training technology. It automates management by training dialogue through the computer. In the creation process of the "Reference book" computer means of training had been developed by Moscow State Academy of Food Production during 1980-96 were used.

PART 1.
THEORY

CHAPTER 1.
BASIC REGULATIONS

1.1. Analysis of computer training means (CTM) created in different organizations has allowed making the following generalization.

The computer process of teaching is individualized, automatically adapted to each trainee, checking the quality of mastering of an educational material with given by the teacher frequency, including check of the given purpose of training on each step of training and bringing the necessary changes for this purpose in the course of teaching process.

Technology of teaching, management process by training dialogue does not depend on subject area, rate of education, the type of educational institution, the form of training and the other external parameters. The technology of teaching depends only on the didactic purpose of the given teaching step. Each didactic purpose requires management algorithm of trainee cognition activity.

Trainee's cognition activity can be described in various forms: activity breakdown turned to the list of activity, generalized (knowledge, competencies, skills).

Possession by logic methods of thinking, planning of the activity, skill to control the activity, skill to summarize an educational material may be included into new activity along with specific one, caused by the subject area.

Peculiarity of computer teaching process:

- in a mode of individual dialogue,
- adaptation to each trainee, on various parameters,
- discreteness of process, consisting of separate training steps, process control on each step,
- management script realization of the training process, described by teacher.

Computer teaching process does not replace the teacher, but it only carries out a part of his functions.

The requirements to management process of mastering at each training step:

- check of activity, included in the system of preliminary knowledge; if the given activity is not mastered, it is necessary to correct the model of trainee activity,

adding the necessary dozes or steps of training;
• control of fulfilment of the assignments on new activity; the control method must correspond to a stage and required level of teaching.

Levels of mastering.

Level of preliminary acquainting: motivation (the tasks are not solved); drawing up of a tentative activity basis (TAB).

Carrying out to an intellectual stage of mastering:

Formation of activity in embodied form with support on TAB,

Formation internal speech activity without a support on TAB,

Fulfilment of activity in external speech,

Fulfilment of activity in the form of internal speech.

Leading of competencies and skills up to a given level automatically.

The check of the achievement in specific mastering level requires the control method. The higher is level of mastering, the more difficult becomes its technical control. For example, control of "creative mastering level" requires standardless level of control, with using syntactic and semantic methods of the control. It requires input of the answers in strict entrance language of investigated subject area.

The management of mastering process can be actualised only in the presence of:

• model of activity,
• analysis of trainee's actual activity,
• definition of details and their divergence,
• definition of necessary correction for achievement of activity model and delivering of the appropriate instructions to trainee.

General requirements to the control:

• the time of activity fulfilment should not influence on estimation of activity (except for cases of training of some specific skills concerning certain trades);
• in order both advanced and lagging trainee should not lose interest to teaching, firstly it is necessary to check the correctness of final result realization and let answering correctly go to the following step. If mistake is found out, one ought to transfer to a lateral branch of teaching with bringing the necessary correction in a course of teaching.

In computer process of teaching *the computer carries out a following function:*

• under the given programme or at the choice of trainee gives out the next doze of the educational information;
• gives out the tasks and exercises for development of knowledge and skills and checks correctness of their fulfilment;
• distinguishes the type of errors have been made;
• carries out the analysis of teaching history and determines the most probable reasons of errors;
• checks the achievement of given mastering level;
• checks achievement of the local and global purposes;
• gives out texts and materials, necessary for correction and continuation of teaching process;
• conducts the protocol of teaching history.

CTP provides adaptation to:

• the rate of work,
• the level of initial preparation, including additional dozes,
• the level of general preparation (capabilities), giving out helpful texts,
• the character of thinking (by changing the form and methods of educational material's exposition),
• the current errors, giving out particular explanations on the basis of error type recognition,
• the reasons of errors (lack of knowledge in the previous sections) on the basis of a teaching history analysis.

CHAPTER 2.

TYPICAL COMPUTER TECHNOLOGIES AND MEANS OF TEACHING

For the basic purposes of teaching, which are used the most frequently in educational process, typical CTM are developed, the block diagrams of teaching dialogue management training with «dutchmen», which require only «adjustment» under author's computer technology of teaching and fillings of ready forms by the subject contents are constructed.

Conditional name of computer technology of teaching	Didactic purpose
DEMONSTRATIONAL	Intensification of good layout of material exposition
TESTING	Definition of a testee suitability for accomplishment of particular activity
MOTIVATIONAL	Belief the trainee that the study of the material is in his interests
SUPERVISING	Definition of educational material mastering level on the given grade stage
SELF CHECKING	Self-checking of mastering level according to trainee's will with a choice of sections or themes
TRAINING	Development of skills and competencies in specific activity with an automatically given level
TEACHING	Transfer of knowledge to trainee in certain subject area
MATHEMATICAL MODEL	Training of skills of mathematical description of the physical phenomena and complex systems and to decision methods of received equations systems
EDUCATIONAL Automatic Process Control System	Development of skills and competencies of complicated technological processes management
EDUCATIONAL Computer-Aided Design System	Training to ability of work with real Computer-aided Design Systems
PROBLEM	Training to search methods of decision in problematic situations
EXPERT	Training to methods of decision acceptance in conflict situations. Identification of complex objects or situations
TEACHING-SOLVING	Training to skills of the problems decision with using of ready software packages (SP)
INTELLECTUAL TRAINING	Purchase of creative decisions skills of sophisticated problems
ELECTRONIC TEXTBOOK	Organization of multi-target training at distance and correspondence education

CHAPTER 3.

A TECHNIQUE OF COMPUTER TECHNOLOGIES TRAINING DEVELOPMENT

Author work stages of computer training technology:

1. Choice of a theme (section).
2. Definition of global and local purposes of training.
3. Scheduling of handbook plan, collection of material, allocation of basic concepts, definition of the basic logic mental receptions, allocation of individual problems and invariant essence of learned material.

4. Definition of logic sequence of an exposition. Segregation of motivation stage.
5. Definition of exposition variants quantity. Allocation of stages.
6. Breakdown of an learning material on teaching dozes (steps): comprehending of the problem, drawing up of the TAB scheme (algorithms of activity), training to new kinds of activity, formation activity in embodied form with a support on TAB, formation of activity without a support on TAB, formation of required degree of automatically in trainee activity.
7. Logic scheme choice of management of teaching dialogue in dependence on the local training purposes.
8. Writing of the educational texts dozes.
9. Selection of typical problems and control tasks.
10. Definition of tasks quantity (depending on given level of mastering and necessary degree of automatically).
11. Control methods choice of trainee's answers depending on given level of mastering.
12. Writing of assistance texts and errors explanations, found out by trainee's work in a computer class.
13. Writing of helps texts and decision plans explanations of tasks for trainees, have already made some errors during decision of given problem etc.
14. Scenario description of management by teaching dialogue.
15. Development of printed distributed materials for providing of trainee's work in computer classes for given CTT.

PART 2.
PRACTICE

In the second part of "Reference book" fragments of computer teaching means (CTM) are contained, which are used as examples of typical Computer technologies of teaching (CTT) and CTM:

- Control CTM and self-checking of skill to solve problems on complete rate of physics for secondary school.
- Trainer of skill to solve problems on physics on secondary school complete rate (with a choice of section at trainee's will).
- Fragments of trained CTM on physics for the students of higher school on divisions "Mechanic" (kinematics, dynamics, work and energy, lows of preservation, harmonic motion, molecular physics and thermodynamics) and "Electricity".
- Fragments of trained CTM on strength of materials faculty, themes: "Bend" and "Complicated stress state".
- Educational computer-aided design (CAD) system fragments on machines designing course.
- Expert CTM "Determinant yeast cultures".
- Demonstrational CTM "Conveyor technology of CTM development".

The last CTM shows organization of work at creation CTM developed in Information technology of teaching department in Moscow State Academy of Food Production, which has allowed 1-1.5 orders reducing of the time needed for development and introduction of CTT and CTM in educational process.

QUALITY ESTIMATION OF SYNTHESISED COMPUTER SPEECH: PSYCHOLOGICAL ASPECTS

F. Laugalis, A. Bagdonas (Lithuania),
V.A. Usik (Russia)

New technologies based upon Synthesised Computer Speech (SCS) are actively being developed for the last time. They are concerned with various fields of human activity as follows: communications and connection, training and services for blinds and persons with serious vision disorders, publishing (for example, edition "audio" books and newspapers) etc. In the process of SCS software and hardware development while defining the optimal variant, the psychological estimation of sound quality is just necessary. As far as we know, the methods of this kind are not yet developed either for Russian Synthesised Computer Speech (RSGS), or Lithuanian Synthesised Computer Speech (LSCS). That's why the major objective of this development is a consideration of some psychological problems, arising in the course of elaborating of these techniques and presentation of preliminary results of their implementation in the Laboratory of Special Psychology (Vilnius University).

In various laboratories of the world the quality SGS is usually estimated by two following parameters: legibility and acceptability. While the legibility can be measured both in the objective and subjective ways, the acceptability can be measured only in subjective ways. The term «legibility» usually means a possibility for perception and recognition of SCS, and "acceptability" means a subjective estimation, which student makes. The terms "subjective" and "objective" measurements are defined variously as well in various laboratories of the world. It is possible to indicate two basic attributes, which are characteristic for objective measurement of SCS quality. First one means, that the measurement is rather relative, than absolute, that assumes measurement in a situation of comparison. In our case, SCS is compared to the speech of a professional announcer (a referential comparison).

The second attribute of objective SCS quality measurement is the availability of the *objective* parameters. In our case this number of the correct, wrong and changed answers, reproduced by the student after listening the tasks of the test assignments on legibility. The term: «subjective measurement» usually means estimation based on the expressed opinion, physiological orientations or emotional impression connected with SCS. The given parameters are usually estimated with scores by means of the special questionnaires.

The SCS legibility depends first of all on quality of synthesis the sounds of speech (vowels and consonants). Sinusoidal waves (with or without overtones), acoustic equivalents of the letters, double phones and etc are normally used for evaluation of the quality. As a material for quality estimation of sound synthesis we used acoustic equivalents of Russian and Lithuanian letters (first sub-test of the whole legibility test). This selection is determined by fact that from the practical point of view SCS application in the communications is more substantial than measurement of the frequency and amplitude characteristics of transient processes. The second part of measurement technique of SCS legibility comprises the sub-test of the words. It includes 30 words, which are selected and mixed in a random mode from three parts of the frequency dictionary: ten words of high frequency, ten words of average frequency, and ten others of low frequency. Such selection of words is caused by the necessity for stabilising and smoothing of objective complexity of speech and possibility for creation of the parallel versions of the test. Availability of the parallel versions allows the balancing of dynamic the effects of testing (knowledge accumulation, exhaustion and etc.). All the words used were sensible because processing of senseless words (such words are used for an estimation of synthesis quality) are, apparently, made by more primitive brain nerves mechanisms as compared to those are sensible.

For example, as psychological researches show, the acoustic hearing apparatus aids with matrixes of microelectrodes implanted into the middle ear provide a good distinction by the person of complex sounds of a symphony orchestra, but are absolutely unsuitable for perception of verbal signals.

In other words, intelligent information (words, sentences, text fragments etc.) is more preferable for testing SCS quality, especially if the tested speech is used for communication, as it is in the case of our research. Thirty short sentences (consisted of 5-7 words) made up the third sub-test for objective measurement of SCS legibility. Each of these sentences included one word from the second sub-test.

These sentences were selected to represent communication speech. They were included with aim of covering prosody elements, influencing SCS legibility. This sub-test benefit is that it increases, for example, SCS capacity in the course of computer skills training for blinds, at editing of the so-called «audio books», and in the case of operating with large text files in publishing activity as well. This sub-test also takes into account the factor of a context and anticipation, which are the most important feature of the perception of any coherent legible speech.

SCS acceptability was measured, according to the questionnaire mentioned above which consists of the open and the closed question types. A part of these questions can be related to standard and easy-defined type (for example, age, sex, time-duration of work with SCS etc.). Another part of questionnaire demanded certain experience of self-supervision (this part was on five-grade scale estimation). In the beginning of the research the audimetry tests were made with the purpose of determination of the adaptation degree and probable hearing damages of the students. The procedures of calibration and training were also used. The SCS measurements were spent on 48 students (20 blind pupils and pupils with serious vision disorders who were trained to work with the computer, and 28 students of the second rate on a speciality psychology). A part of the students had certain experience of work with SCS, and other had not; the women add up to 52 % and the men add up to 48 %. The major part of the students possessed experience in calibration, and blind persons and persons with serious vision disorders had experience of training. All students spoke both Russian and Lithuanian. The original version of SCS was used that is implemented in the process of blind persons work with PC at LOGOS association.

Adapted "Apollo" LSCS version was used that was developed by "Dolphin" company and is implemented at the computer centre for training blind persons and persons with serious vision disorders in computer skills. The procedure of measurement consists of 4 series, and the measurements were carried out for each student individually. That is there was Russian announcer (RA) for RSCS and Lithuanian announcer (LA) for LSCS. A quality estimation of the synthesis according to acceptability parameter was carried out after legibility test procedure. The research, as a whole, was made with the maximum account of the psycho-diagnostics requirements. Forty-nine parameters of SCS legibility and acceptability were found for each student after measurements during primary data processing. Hereinafter these data were subjected to functional and statistical analysis. In addition for comparisons in pairs both correlation factor and *Student criterion* were determined with the purpose of estimation of the statistical reliability of distinctions between average values ($p < 0{,}05$).

Preliminary analysis of the experimental data revealed two effects that are of primary concern from the point of view of methodology are directly connected with validity of our test of SCS legibility.

The first effect is sometimes referred to a as «effect of a ceiling». The essence of the above effect is as follows. The value of the parameter is a maximal one or close to it and thus the two compared kinds of speech cannot be distinguished. In our case the percentage of the correct answers for the first sub-test for RSCS and RA equals to 36,09 % and 94,68 %. For LSCS and LA these numbers are, accordingly, 67,33 % and 96,83 %. Thus, legibility of speech for both announcers approaches to 100 % and almost does not differ. Hence, by means of the parameter of number of the correct answers we cannot distinguish the above types of speech of excellent qualities (RA and LA). This is just the above-mentioned "effect of a ceiling".

In a case of comparison in pairs RSCS - RA, LSCS - LA and RSCS - LSCS this parameter differs widely suggesting that the sub-test is valid for evaluation of SCS "of medium quality" (RSCS and LSCS). Basically, the same result is demonstrated in the other effect, "effect of floor", when numbers of the incorrectly reproduced answers for very good speech (RA and LA) do not differ and approach to zero. In the same time, in the case of referent pairs, such as announcer-SCS, this parameter is a revealing one.

These both effects, "effect of a ceiling" and "effect of floor", are found out and for the cases of the second and third sub-tests, that is also an indirect evidence of the sub-tests validity for estimation of the medium SCS quality.

It is necessary to note that there is no common estimation for our test of SCS, as well as in great majority of cases in other similar laboratories, i.e. we use the results of separated sub-tests separately. With the purpose of determination of a common score for these three sub-tests a standardization procedure is necessary which requires both special computations and large and diverse database. Such procedure is rather complex and expensive; therefore in the world there are only few standardized tests (for example, for English language). Thus, our test is not standardized yet, but, as we can see, it has all attributes of validity for estimation SCS of medium quality.

The second part of experiment comprises SCS acceptability measurements. It revealed the following fact. The RSCS score is 65 % lower as compared to RA. Accordingly, the LSCS score is 57 % lower as compared to LA. Comparison between RS and CS did not reveal any statistically plausible distinctions. Furthermore, RSCS score is estimated 10 % less acceptable in comparison with LSCS. Basically, the identical tendencies are presented by practical work experience with blind people who use SCS for dialogue with the computer. The above concurrence can also be considered as indirect confirmation of the validity of our technique of SCS acceptability estimation.

It is also possible to note, that preliminary results of estimation of RSCS and LSCS quality, for the first time received in our laboratory, are represented to be quite acceptable for comparison and selection of the developed SCS systems. Hereinafter, both database expansion and experience accumulation are necessary in the field of quality assessment of various SCS under various and for various students. In sight, it shall result in substantial increase of measurement accuracy and, eventually, in the development of standardization procedure for a test.

INFORMATION TECHNOLOGY METHODS AND MEANS OF DIFFERENTIATED TEACHING OF SPECIALISTS AND PC USERS

E.A. Manushin, L.N. Puchenkov (Russia)

Modem status and directions of development of personal computers (PC) and information and communication technologies are characterized by increase of specific weight of use of these technologies in various areas of business, bank business, manufactures, military engineering, science and education.

There is a necessity for continuous outstripping training of various categories experts and users due to occurrence of a plenty new PC hardware-software means and networks and necessity their the prompt development and use in new information distance technologies.

Recently in various western countries a pronounced tendency towards removed offices' technology development has appeared which has a number of serious advantages in comparison with the traditional forms of company employers work organization. In the list of problems, which are carried out by the users of such offices, an important place is occupied by the question of software and technology teaching.

At the moment in educational institutions and centres for training of the experts is carried out in the frameworks of the curricula and programmes, which not always take into account individual qualities and level of learners' preparation.

At the same time in practice each teacher in his educational group always picks out three levels of learners as follows: very well advanced; advanced (basic staff on which the programme of training is designed and which are the basic object of teacher's attention); constantly lagging behind.

The curricula and the programmes of training are aimed to advances students, which make the majority in each educational group. For successful training in view of realities of the present period it is necessary to create or to use completely those methods and means of training differentiation and individualization, which were hitherto inaccessible for implementation in full measure. For the most part, these methods and means comprise information technologies for distance differentiated training.

Modern information technologies allow improving conventional and to develop new training technologies for differentiated distance teaching of the experts and the PC users.

Let's consider the fundamentals for development and design of such technology.

The integrated teaching system includes a number of local networks consistently connected by channels of internal and external communication with the help of which individual problems of training process are carried out at all stages. Depending on accepted model of training various technological circuits of training processes can be realized. As an example of management object at the basic stage a learner is considered possessing sophisticated dynamic characteristics, with the account of which the teacher carries out optimum control of the teaching process using accepted training methods and means.

Theoretical basis of differentiated approach is determination and subsequent use in the teaching process of individual distinctions, abilities, peculiarities of learners using new technologies of differentiated teaching. Realization of this approach on the basis of information and communication technologies is the most reasonable.

Each person as in individual can be characterized by a set of psycho-physiological characteristics, being common for all, and at the same time allowing to receive individual «portrait» of each person, to evaluate his psychological properties, abilities, features of character, inherent only to him. From the point of view of training and subsequent fulfilment of professional duties, connected with PC work. The most important are the following psycho-physiological characteristics of training objects: type of central nervous system, memory, thinking, attention, type of the person, sensomotoric reactions.

The difference of potential abilities of learners demands from the teacher an individual approach to each learner or the group of learners possessing approximately identical level. Three forms of differentiated teaching are possible: a grouping according to the teaching level on this or that course (division into flows); trainee structure modifying course depending on the level of knowledge achieved by them (temporary educational groups); individual training under the guidance of the teacher or using teaching programmes. During realization of the individual approach a standard three-profiled curriculum is constructed which is added by educational opportunities for the pupils with abilities lower average on one hand, and for talented - on the other hand. Depending on the results during teaching, transition of any learner is possible to the higher or lower «track», i.e. each trainee can study the course in his own rate.

Didactic «matrix» of the process of teaching is realized on micro- and macro levels. In the first case the training will be carried out within the framework of educational institutions of a certain type, specialized profile programme, flow, group. Macro level of educational process is interaction between the teacher and the certain students, individualized curricula or teaching programmes.

One of the forms of individual training realization is organization of groups with a various level of the educational tasks and individual rate of cognitive progress depending on the progress in the study of separate subjects, with «sliding transitions». «Sliding transitions» allow trainees to use all his opportunities for transition during training towards the higher level and educational programmes.

At such approach a role of the teacher significantly raises. He ought owes with the help of the various tests, experts in the field of the teaching contents and advisers to determine, which knowledge should get each student. Then he points out at and explains what tasks and materials shall be mastered by a student. He also indicates what ready for use training materials shall be used. The teacher plans and organizes the programme of training, manages the training process, acts as an adviser of the trainee and organizes teaching environment. His role is to promote the students in planning and estimation of educational work, to stimulate development of their experience, to help to them to realise alternatives at reception of the decision, to provide them by various educational materials for differentiated teaching.

The realization of individualized training is carried out in the frameworks of didactic system according to the beforehand planned programme, designed for the certain individual. This programme is acquired with inherent for each student rate; the learning process is constantly supervised and estimated. The programme consists of three phases: the entrance control, branching of training programme to the intermediate control on the important sections and the terminal control on the whole course.

During the entrance control each student passes preliminary testing, during which there shall be revealed trainee's reference as follows: individual «portrait», the level of knowledge, skills in this or that cognitive area. Each student approaches to new cognitive problem with unequal luggage of earlier acquired knowledge, and skills that are necessary for its overcoming. Therefore effective cognitive programme ought completely to take into account already is able to operate and what has not yet reached. The teacher determines what necessary for further cognitive progress knowledge the student has already mastered. According to the results of the entrance control each student is previously allocated to one of the three levels.

On the second phase the teacher selects the programme of teaching in conformity with a level of the student and offers to the plan of training.

On the third phase the testing is carried out that results in determination of the achieved level of knowledge and skills as compared to the objectives of teaching. Then the teacher makes a decision on the estimation of results of comparison. The teaching programme for individualized training is formed according to a principle of «blocks» or «educational packages», which are intended to give the student an opportunity to take possession by certain skill or representations, or to advance in interesting for cognitive area in conformity with his own rate. Educational packages or blocks have the form of printed materials, which open certain aspect of the contents of education or the area of cognitive interest. In these materials the specific objectives of teaching are formulated, instructions for the students are presented, the references information sources on a theme and all kinds of educational activity of students in this area are specified.

The quality of teaching depends on quality of particular development and teaching methodical materials, which is possible to consider as engineering part of teaching process Essence of individualized training comes to splitting of educational contents on separate conceptual-informational fragments (blocks, educational packages), connected among themselves by structure, contents, and complexity. Each student receives a set of educational materials for passing in his/her own rate. It allows revealing the typology of the individual cognitive peculiarities in teaching process.

Some students master an educational material in the best way, if they have an opportunity «to open» basic laws and fundamental integration. Other students prefer the situation when the educational material is structured deductively, and not inductively, in other words, they pass from the general to the particular, instead of vice versa. Some students are trained better during direct and specific experience accustoming to various things, other prefer mediated experience or verbal method, when they simply hear. Some students are trained better when their cognitive experience is divided into short blocks, acquired for certain interval of time. Others prefer the conditions of complete submergence into cognitive experience without any short-term interruption. Some students are trained better, being under a direct management and control on the part of the teacher, others prefer being completely independent. Some students make progress better at presence of stimulus, others - when they can really feel it; thirds prefer to perceive the information in an oral presentation. There is no universal given optimum approach to the process of teaching since the students differ from each other.

Theoretical basis of process of teaching is didactic, one of the branches of which, connected with use the personal computer, is cybernetic didactic. It was shown, that during mastering of the student educational material he consistently advances among various levels of memory: direct, short-term, long term. These levels of memory are characterized by throughput duration of presence in memory. Quantitative parameters of memory of the students of various age groups enable to estimate approximately the speed of mastering of the given educational material and cycles of repeated training for maintenance of a necessary level in system of individualize training. Cybernetic didactic also considers psychological aspects of training, allocating six most general purposes of student: knowledge, understanding, application, analysis, synthesis, and estimation.

In a teaching system the ultimate objectives shall be achieved for fixed term with the use of appropriate methods and means. For the successful decision of this problem the students, as an object of teaching, shall have, depending on the purposes of training, both individual psycho-physiological properties, determined by initial level of basic training and necessary professional work experience.

Each group of entrants ought to pass the entrance control. Initial level of basic training and necessary professional work experience is determined with the help of supervising rates. The list of questions with variants of answers is previously developed by the author of a course for each training programme and then it is made out as supervising course. The algorithm of processing of the results is defined by the author of the training programme according to the requirements to the basic training, experience of practical work and individual properties of an applicant.

Before the beginning of the differential training the teacher ought to take into account three factors for each trainee: a level of abilities; basic training; professional experience on the theme of teaching. Testing procedure is carried out with the help of special supervising courses and diagnostic tests with the purpose of data obtaining for each entrant. During the testing each answer to proposed question, in dependence on its contents, is estimated in numbers, and according to the appropriate algorithm total quantity of numbers is defined for each tested person. Then results of an applicant's testing are processed on accepted algorithm as to three groups of the tests, and with the account to weight factors of separate factors of influence. Total numbers and appropriate level of a student are calculated. According to results of testing and of a subsequent interview the teacher defines the structure of differentiated teaching and accepts that or other decision about including an applicant into the staff.

The level of abilities is estimated with use of a package of psycho-diagnostic tests, which allow to allocate basic psycho-physiological, psychological and behaviour parameters of an applicant (type of nervous system, memory, level of thinking, attention, type of the person).

Under each test an applicant collects the appropriate quantity of members, which is compared to control (base) for each of three levels and then his level is determined. Then after testing on all tests of the package through appropriate algorithm the level of abilities of an applicant is determined.

The base training is defined using specially made questionnaire. Determination of the level of basic training is done with the purpose of receiving of the information on the previous applicant's preparation in the high or secondary school, and also retraining and increase qualifications on information technology and computing engineering for the subsequent estimation of an opportunity of his successful passage and finishing of the programme of forthcoming training.

Quantity structure and the contents of questions is determined by the programme of forthcoming training and by the requirements to trained, listed in this programme. The questionnaire is realized as supervising system on PC. Basing of the results of interrogation the quantity of numbers is determined and is compared to control sums on first, second and third levels. Depending on collected numbers appropriate (1-3) level of the applicant is defined.

The necessary level of professional experience is determined by a teacher with the account of the final level of training, which a student shall reach after the end of training. Estimation according to this factor is the least formalised way and it may include three stages:

- answers to theoretical questions on hardware-software maintenance of PC;
- fulfilment of the control tasks for check of skill of the applicant to work with PC software in normal modes;
- fulfilment of the control tasks for check of skill of the applicant to work with PC software in failing situations and at malfunctions.

After realization of the assessment on each of the listed factors each of applicants receives the appropriate quantity of marks, which is compared to control sums for each level and, depending upon collected scores, an applicant is allocated to the first, second or third levels of professional standards (experience).

After realization of applicant's assessment according to three listed factors and using appropriate algorithm his initial level is previously defined as to the beginning of training (the level is specified after an interview). Then the probability and ability of an applicant is defined during the given term of training to reach the purposes of training and after fulfilment of terminal control tasks to receive appropriate certificate.

After realization of the above mentioned control the whole quota of applicant is divided on three groups:

1. Group of the students with an initial level above the average.
2. Group of the students with an average initial level.
3. The group of the students with an initial level lower average.

As practice and experience of the authors shows basic structure of the students concerns to 2-th groups with an average initial level and makes on the average from 70 % up to 90 %. The first and the second groups make from 5 % up to 15 % of the whole quota.

Considered approaches towards realization of information technology methods and means of differentiated teaching can be put into the basis of remote training in the presence of appropriate hardware-software means of remote access between centre training or a teacher and a student, since the a major factor in this case is the presence of methodical and programme support of the differentiated teaching technology. At distance training the determining factor is the speed of the information exchange by removed users and choice of the possible interaction circuits between a teacher and a student for various ranges of actual rates of the information transfer.

NEW INFORMATION TECHNOLOGY OF TEACHING: THE CONCEPTUAL ANALYSIS

Z.I. Mashbits, M.L. Smulson (Ukraine)

In the range of scientific problems, the decision of which is necessary for informatization of education, the leading place belongs to psycho-pedagogical problems of development and application of new information technologies of teaching (NITT). Currently the conceptual analysis, designing and psycho-pedagogical examination of NITT efficiency are the most prioritise. Any of these problems can not be solved in divorce from others, and the research of each of them should come true in a context of others. So, for example, we consider unproductive conceptual analysis of NITT without account, that they should be projected; it is impossible to carry out effective NITT designing without a support on their conceptual analysis and etc.

Mentioning about NITT we mean a lot of technologies, which use information media in educational process and in the first rate a computer, while using it as a means of teaching.

Teaching is a dialogue process. The method of dialogue interaction organization between students and teacher (computer) means, to our mind, carried out technology characteristic of training. We mean either external or internal dialogue, its symmetry, application sphere, pedagogical set level etc. For the NITT characteristic essential is such management parameter as modality of information exchange (we mean modality of presentation it by computer and modality of students messages).

Taking into account the fact, that recently diverse training organizations have been used with computer help, and along with individual form, more and more frequently various group forms of work have been used, essential characteristic of teaching technology is the form of its organization (note, that these forms are rather distinguished on structure, ways of students interaction among themselves and between them and computer).

The important NITT characteristic is the indication of those managing functions and ways of their realization, which computer carries out. This parameter we have titled «organizational aspect of management» (for example, adaptive, individualized, reflexive management etc.).

At last, very essential characteristic of teaching technology, especially the newest technologies, is distribution of management functions between computer and learner. We mean the question, what functions of management are delegated to student. This characteristic reflects organization level of educational activity, dynamics of transforming to self-training.

The conceptual analysis of teaching technology as a system of knowledge, concerning training process, assumes first of all specification of its status, association of teaching technology with its theory. While definition of technology teaching status we start from a rule, that neither psycho-pedagogical theory can be directly introduced in process (mentioned idea concerns not only the theory of educational activity, but the training theory). It resembles, for example, how the laws of physics cannot be directly used in manufacture. The necessary condition, thus, is application of theory to technology i.e. creation on its basis the appropriate technology.

The technology of teaching acts as some intermediary between the theory and practice of teaching. We can not agree with those authors, how consider as equal the technology of teaching and its designing. And we think that the latter can come true not only on technological teaching level, but also on the level of its theory and practice. Its peculiarity lies in the ways of the project description.

One of the most vulnerable points of the modern theories of teaching is the difficulty of their application to technology. This comes through the following reasons. Firstly, their principles are formulated in such a way, that they hardly can be practically applied. Secondly, no theory is able to cover all aspects of teaching process, while technology should take into account all aspects without exception. Taking into consideration mentioned factors, the main requirement to the teaching theory is possible to formulate as following. It should be appropriate to technology, i.e. should ensure an opportunity to describe the operations as a system of elementary ones.

We should indicate the following requirement. The theory of teaching and educational activity should be interconnected. Only in this case they can be the theoretical basis of teaching technology. Unfortunately, today the learning theories (theories of educational activity) and teaching theories develop independently from each other, though the elements of their association take place in all theories. Necessity of complementation of the theories of educational activity and teaching ones is caused by the fact that any teaching theory always proceeds from definite representation about educational activity. Similar situation takes place at development of the theory of educational activity. It proceeds from definite idea concerning teaching. Even in the case when there has been put a mark of equality between the learning theories and teaching in class, it is not possible to completely disengage from teaching in any learning theory.

At last, the third requirement to the theory of teaching is that it should base on psychological mechanisms of training, describing interaction between its subsystems. In teaching, considered as system .education, teaching and educational activities act as subsystems. Psychological mechanisms in teaching describe interaction between them.

Along with well-known mechanism of teaching, common to arbitrary control system (feedback), we underline also the following two psychological mechanism of teaching.

1. Complete determination of educational objectives: this mechanism opens transition from training influence to an educational objective under the influence of a set of factors, including situational ones. Just this mechanism allows to prove regulations, that in the system of teaching the student acts not only as object of management (teaching activity), but also as the subject of educational activity. Complete determination of managing influence takes place in all kinds of management, object of which is the person. Peculiarities of this mechanism functioning in the system of teaching are connected with the fact, that in this case the decision of the problem acts not as the purpose, rather as means of its achievement.
2. Consider the psychological mechanism of dynamic

distribution of managing functions between learner and trainer (computer). This mechanism is inherent only for teaching. A role of this mechanism significantly grows in NITT conditions, since there is real opportunity of dose transfer of management functions to students. The offered approach allows:

a) to reveal one of the basic reasons of experimental research results inconsistency, concerning various teaching technologies comparative efficiency; this reason consist in the fact, that not all technological parameters were taken into account in the research process;
b) to plan new lines of the theoretical designs analysis, beginning from teaching level, called «an explanation of new material», up to new paradigms of educational process («learning without teachings, «learning by way ofteaching»);
c) to allocate the basic components of the teacher and students activity, which should be discounted at NITT designing.

The information technologies of teaching introduce modifications to all aspects of educational process. They render essential influence on the activity both of the teacher, and students, while comparison between them and «traditional» technologies is not quite pertinent. It is necessary to take into account new opportunities of educational process construction.

Institute of psychology of Academy of pedagogical sciences of Ukraine, Kiev

THE CONCEPT OF THE ELECTRONIC TEXTBOOK AND NEW INFORMATION TECHNOLOGIES

V.G. Mitrofanov, V.N. Kareev,
V.N. Balabolin, B.L. Platonov (Russia)

The information technologies in education are the key point of successful development of information technologies for a society, being linked with expansion of a role and extent of influence of intellectual activity modes diversified over human life.

The computerization of education and, in particular, methods of distance teaching are heading at the moment in humanitarian areas of education mainly. Technical branches of science because of their complexity and large volumes of information are not practically considered at the creation of systems of distance teaching. At the same time the necessity of distance teaching in technical branches of science, especially in the field of mechanical engineering, even more important, than in humanitarian areas. It is confirmed by the fact that designing and technological designing is a creative process, caused by the complex inter-disciplinary links and requires a plenty of references and graphic materials. A support of interdisciplinary links and the creation of systems, ensuring a feedback between these and the persons under training, can be provided only by essentially new approach to a process of teaching and establishing of electronic teaching systems - electronic textbooks forming teaching as a course combined with various spheres of knowledge.

The main reason of obstructions at creation of new technologies of. teaching is a serious contradiction between an essence of traditional contents of educational subjects and inter-disciplinary character of computer medium used.

The further development of computer technologies of teaching should follow the way of content reforming on the basis of non-standard ideas and creations of new integrated educational courses.

Currently the main purpose of teaching becomes not only mastering ready knowledge, but also the assimilation of information, tracing the ways of information interchange and use as the means for accumulation of new knowledge.

In the present work the new approach to formation of a computer base of knowledge and a methodology of establishing of the teaching courses within the available knowledge spheres is proposed.

At traditional approach to the process of teaching all students must get knowledge within one tempo. The use of a computer will allow to each student to choose an optimum for him speed of reception and mastering of material, to supervise oneself, to review the earlier studied material etc. The computer provides and active feedback with a learner, analyzing the results of training and changing a tempo and technique of teaching depending on the results of mastering the educational material.

Electronic textbook is an electronic image of an information all over the educational material (books, lecture, subjects and etc.), elaborated on a computer and complemented by the functional opportunities for the realization of teaching process: by reflection of mutual findings of subject sections and interdisciplinary coupling; by the explanatory means, demonstration, practising and control. The listed opportunities are given to learners by means of the user interface. The electronic textbook similarly to book has a table of contents accompanied by a specialized index of subjects, ensuring the contextual references to any objects, among them the graphic, audio- and video-objects. In addition to this, the electronic textbook presents the associative linkages, and also pictorial representations of an educational material can be realised. The electronic textbook, except the content and technical software, includes also methodical support, which ensures the realization of training with the problems in hand.

The electronic textbook is formed on the basis of a specialized catalogue, organized as a graph. This graph sets thematic or any other user's partition of the information of a textbook (sections of the book) into groups, probably, partially intersected. A user has an access to the information of a textbook by two ways: one - through the structure of a catalogue (graph), the other - through the coupling references in textbook sections. As fractional unit, from which an electronic textbook content, is constituted concept of a generalized paragraph is used.

The paragraph includes all elements of information, contained in the textbook. Among these elements are textual (indent-sentence), graphic and tabulated (table) information. The generalized paragraph includes one more additional element - a binding unit. This element allows to set information binding between the paragraphs and their elements.

The offered structure of the paragraph allows to proceed to the representation of the textbook as oriented hyper-graph. This hyper-graph ensures a thematic or any other user's partition of documentation base into groups. The paragraphs act in a way of graph nodes while the element of paragraph «binding» defines the structural links of graph. The hyper-graph's modes were named a document. Thus, hyper-graph will consist of the documents, connected with each other. The representation of the document structure in a way of graph opportunity to create systems of interconnected documents. The proposed information structure of data storage allows solving several problems simultaneously:

a. to arrange a simple and handy structure of information;
b. to ensure a purposeful or a random processing of this information;
c. to modify a structure of information, not changing its content.

From the standpoint of the chosen information structure capability any document, the book etc., being in hyper-graph structure can be represented in their natural form. At same time the book is represented as a two-level (multilevel) document. The first level of the description defines the structure of the document, i.e. contains the titles of sections, included in the document, and references to appropriate sections. On the second (subsequent) level of description there are the sections, that include essence of the document. Depending on requirements to the quality of sections the chapters, the paragraphs, indents, drawings and other structural items of a document can be accepted. Thus, an electronic pattern of the book has usual and habitual for user structure and does not require a special preparation for its formation. The hyper-graph structure provides also a support of data structure through a checking block of system. The catalogue of cyclic checks control series, the frame and the elements of frame the control question, variants of answers drawings, helps and repetitive cycle are referred to is the elements of frame.

The main feature of a hyper-graph information structure is the fact, that by means of it the database is transformed to the base of knowledge. The hyper-graph structure allows to impose on existing information the additional links and to create the new information structures. Upon description the necessary structure of links between data sections, it is possible to set up specialized training courses. In this case the content of a course is no limited by one document, but uses the information forma the whole database.

The proposed principle of data structure formation and the methodical approach to structure of an electronic textbook as a hyper-graph, binding various documents, enables to form various training courses on the basis of the same information. The educational courses are divided into following types: first viewing base; auxiliary and facultative.

The courses of the first viewing level enables to receive only contemplate representation about the subject to be studied. They briefly outline the statements, facts and some explanations of the basic paragraphs of a book.

The base level of educational courses gives a significantly required minimum of information, which is necessary for a subject to deal with. The auxiliary and the base courses include a profound study of the material. In conformity with this division the elaboration of a cyclic control of appropriate severity is possible.

Thus:

1. The information structure of the electronic textbook should be organized in a way of the hierarchical hyper-graph.
2. The basic structural unit of a hyper-graph is the paragraph (hyper-document).
3. A hyper-document can comprise a text, drawing, table, formula, field of input, area of dialogue, electronic settlement tables, the structured images, bodies of control (including sound effects), demonstration animated and videocassette, synthetic objects (having the external representation, behaviour, responses to influence), points of an input in the field of a virtual reality and special elements or the points of connections for transition to other hyper-documents.
4. The elements «connection» should address the references to other hyper-documents (textual and graphic).
5. For the textual hyper-documents the elements «connection» should address the references to textual allocation of textual documents, graphic objects and their elements, objects of demonstration and any external programs.
6. For graphic hyper-documents the elements «connection» should address the references to the textual explanations and to the objects of demonstration.
7. The hyper-document containing a group of element «connection» should describe a chain of hyper-documents, specifying a cycle of training.
8. The selection of hyper-documents connections should be performed step by step in accordance with the description or under the conditions.
9. The electronic textbook is integrity of three components: the content, techniques of teaching and a software-technical provision.

New information technologies connected with combining of information within the framework of global networks of computers, enable new opportunities of •structuring and mastering the information, and in a way of a remote access to the data, localised in nodes of this network. These networks assume making use of hypertext structure organization, access and data processing.

The opportunities of hypertext systems are really fantastic, they are the ideal means for electronic textbooks, since they enable the realization of main advantages, which are necessary for elaboration of the changeable and diverse structures of textual sample and graphic information as well as various methods of access and etc. The hypertext systems represent a new class of systems for information management. These systems enable the users to establish, to distribute, to make links and to use files of the most diverse information in a form of text, diagrams, the images, audio-video information, programs and etc.

In general the hypertext system can be taken as a database system, which provides the completely different methods of access and management of information. However, distinct from the traditional systems a database, which have regular, ordered structure, the hypertext systems of database have no strict structure, and the user is free to operate with the information by various accessible to him methods.

The basic idea of hypertext systems consists of a concept of automatically supported connections both inside one document and between various documents. The support of such connections permits to organize the non-linear textual structures. Advantages of nonlinear documents is obvious: distinct from the linear document, for example, the article in a magazine, which is a single-level, unchangeable and having a limited set of references, the hypertext document represents a flexible structure, that can be oriented to a specific user. A learner can, at his will, be limited by the superficial one-level information, not spending time for looking for the necessary documents according to references.

The teacher, while executing the hypertext document, can supplement it by new references, to update separate parts of the document, not changing the content of separate parts. The hypertext was determined as an approach to information management, when information is stored in the nodes of a network, connected by links. The information, stored in the nodes can have the textual, graphic or any other type of data. The findings refer to the relations between elements of the information. They can be two-directional, allowing coming back from a subsequent element to previous.

Thus, the proposed concept of structuring of electronic textbook and the new information technologies of data processing are merged together. As a basis for execution of hypertext electronic textbooks it is offered to use the capabilities of language, intended for the description of screen pages on servers. Such approach will allow to make the description of electronic courses in a simple, from a point of view of a developer manner and to use the results obtained for teaching at separate working places, at local networks, and, also, that is even more important, to organize training in global computer networks, such as Internet. Established on this basis, a teaching complex of electronic textbooks allows organizing a uniform information space for methodical work of a teacher and student teaching and will ensure the performance of educational process for the group and, also, the performance of personal and remote modes of teaching.

The complex is intended to be used along with lecture and laboratory studies for groups of the students associated with special disciplines in display classes under a teacher's control and management and for independent processing at personal working places.

The complex and its information support is used in the methodical work of the teachers on establishing, updating and development of educational plans and execution of complex curricula, ascertaining the interrelations between separate disciplines and joint use of monographs and similar teaching material.

The expected effect of educational process and quality of specialist teaching is defined by a raise of information saturation of teaching, intensification of cognitive activity without an increase of loading and moreover the realization of the concepts of individual and distance education.

The developed concept of the electronic textbook allows preparing the automated educational courses various disciplines and can especially meet the realisation of training courses, concerning subjects. The offered technique of execution of the electronic textbook was sampled at elaboration of educational courses on technical and humanitarian disciplines: «The automatic control in mechanical engineering», «The basis of inter-changeability», "Russian history", «Culturology» and the others. The results obtained have confirmed the efficiency of application of given approach at creation of electronic courses of teaching. As a basic means of a software package mapping was used.

The presented technique and practical results of the development of structure, composition, information and methodical provision of teaching complexes of electronic textbooks can be proposed in a way of a typical sample at creation such complexes along with a number of special technical disciplines for technical universities.

DEVELOPMENT OF PRACTICAL SKILLS IS THE WAY TO COMPUTERIZATION OF TEACHING

N.P. Nosov (Russia)

The history of teaching process computerization in a higher school is rather rich. With the first occurrence of computers at higher school the problem arose of its use in course of training of the experts on-various specialities. The programming was the first subject, which the students had to master during their work with computers. First of all, such approach was based upon the fact that high school was supplied with computers, which were perfectly equipped with software aimed at decision of various calculation problems. On the other hand, programming skills, mastered by the students, could be used in various special courses investigated in higher schools. Such approach brought positive results. In various spheres of activity a lot of higher school graduated experts mastered programming in addition to the knowledge in the field of basic speciality appeared. It is precisely these experts began to implement computer information technologies in various spheres of activity.

However, the fact that in present informatics and mathematics are considered as very close disciplines resulted form both well known conservatism of high school and backlog of the development of training technology for students in the field of informatics as compared to the development of the technical means and software. This is also evident from educational standards on many specialities, authorised State Committee for Higher Education of the Russian Federation. In these standards, in particular, such specialities, as jurisprudence, economics and management, marketing, mathematics and informatics are incorporated in common section. At the same time, the share of informatics is insignificant yet in the total scale of experts training. It is no wonder, that in the overwhelming majority of educational programmes on informatics for a higher school give till now basic attention to study that or other algorithmic language for programming. In conditions of the advanced software modern computers, which widely take root into all spheres, this knowledge of programming hardly will be demanded. Moreover as practice shows 80 % of computer use is connected with textual information storage and processing. Especially it is typical for such areas as economics, management, and jurisprudence. Such situation is hardly possible to consider satisfactory.

At the same time, in a number of higher schools of the country there was produced other approach to computerization of teaching. For example, in computer preparation of students of faculty of economics, management and information technologies in the Moscow State Industrial University the teaching begins with formation of initial practical skills in the work with computers. The acquaintance with the computer the students of the first rate start from the work with files, using minimum opportunities of operating system. At the same time they master the practice of work with the editors of the texts. Teaching is carried out by the blind method of computer typewriting. In parallel in a lecture course the students get minimum knowledge about structure the computer functional devices, operating system.

Thus the students from the first day of learning begin intelligently work with the computer, using for formation, storage and running of various kinds of documentation, the rules of drawing up of which are studied by them in parallel course «Office-Work». The students overcome psychological barrier in using by the computer. It immediately becomes for them the assistant in study. The students begin actively use the computer in the decision of learning problems: for preparation of the abstracts, home tasks, course works.

There are decided not only learning problems, but a certain level of professionalism is also reached by use of the computer as of the tool for the decision of professional problems. For example in the first semester the «blind» method of typewriting and basis of office-work are mastering. In the second semester -professional mastering of computer editors, DOS superstructure, target professional practice. About 30 % of the students after this preparation reach a level of professional typists according to the literacy and correctness of the documents registration. About 70 % of the students have a level of professional skills, quite satisfying the inquiries of organizations, which don't have large volumes of the documentary information.

In university the problem of professional step preparation and certification in the field of use the computer is put and realized. The first rate -certification on the assistant of the manager; after second rate - on engineering of the statistics-programmer.

All students of University aspire to an overall performance with the computer by changing structure, introducing in a practical work development of networks, electronic mail and other modern programme and technical means within the framework of the same teaching hours.

THE CONTRIBUTION OF MULTIMEDIA TECHNOLOGIES TO COGNITIVE DISTANCE LEARNING

Erhard Oeser (Austria)

«Cognitive Distance Learning» is a concrete term for the twin programmes of UNESCO, «Lifelong Learning for All» and «Learning Without Frontiers». It unites today's concept of man, well-founded by natural and human sciences, as a living being that is distinguished from all other biological species through its cognitive abilities of uninterrupted lifelong learning from experience, with today's technological methods of disseminating human knowledge without losing any time all over the world. But the problem is how to combine both areas of

- cognitive information processing in man and
- the documentation and technical transfer of human knowledge
- into a general theory of cognitive learning that is more fundamental and basic as a theory of pedagogical practice and strategies.

For the pedagogical process of learning by means of an explicit teaching process is only one among many alternatives, besides other forms of learning from experience by means of trial and error. The general meaning of the concept of «learning» as an active, or in most cases even creative, behavioural adaptation based on previous experience plays a crucial role in various areas of cognitive information processing: for example in biological ethology, in neurobiology, in learning psychology and in the theory of self-learning machines and of course also in the area of global information and communication technology, that is nowadays the physical basis of distance learning.

This new form of learning that emerged from these developments, that reduces spatial distances and that *turns the so-called «information society» into a «global* village», is more than just the technological implementation of information highways, but it must in particular take into account the abilities of the learning individual or the user of these new technologies.

These abilities and the limits of cognitive information processing in humans are based in biology in two ways: learning as a biological phenomenon can be explicated, on the one hand as genetic information transmission and on the other hand as neural information processing.

Any kind of human cognitive information processing, like the processing of direct sensory information or perception or the transmission of «pre-fabricated» information in spoken or written language, is based on this foundation.

Based on our present knowledge about genetic information transmission we can be sure that the human mind is not a «tabula rasa», but that it contains a lot of structural information right from the start, i.e. both genetic and neural information that is determined by the structure of the brain. This structural information is the prerequisite for the brain to be capable of acquiring the new type of fluctuating information.

Unlike genetic and neural information, this new type of information is called «cognitive information», when we focus on the material-physical basis, or as «mental» or *«rational» information, when it is related to human* cognitive information processing that presupposes consciousness.

Human cognitive information processing was originally limited in its natural representation and communication to direct sensory contact with the objects concerned or to oral speech contact to the communication partner. The invention of writing was the first step in a technological revolution of language and has made human communication largely independent of space and time. On the other hand the material carrier of writing means several limitations to communication, in particular the linear access to written text.

The second technological revolution in modern information technologies replaced the slow and inflexible medium with digital electronic storage and transmission, but it continues to be linked to the user or the learning individual, without whom these *information processes carry* no meaning, i.e. do not represent any knowledge. In this sense the basically useful heuristic metaphor of a global information and communication network as a «global brain» is totally misleading.

While every real living brain or central nervous system has a uniting function in relation to its own carrier organism, the body, with this function manifesting itself prior to any kind of consciousness or self-consciousness in the strictly localizable representation of the body in the cerebral cortex (as a so-called homunculus), this holistic function totally misses in a technical communication network. It is thus neither a global brain, nor an overwhelming global intelligence in the sense of old phantasies of AI-research, but rather a termite intelligence, resulting from action and interaction of large populations of individuals who are not tied to this system, but who can log into this system or off any time.

The real user of such a distributed system of knowledge who wants to learn something, can only access a certain part of this global knowledge, based on his/her individual knowledge and abilities, although this knowledge is basically available as a whole without limitations.

The reason is that the learning individual only knows a certain subject field, speaks mostly only one language, understands only part of the symbols and needs time to acquire and process knowledge that is offered in different forms and in several languages.

Although it has been clear for a long time that multimedia systems that link to each other pictures, sound and text in non-linear ways are an adequate means of knowledge representation, because it corresponds to the multimedial sensorial acquisition of information in humans who process the modal information input in inter-, supra- and metamodal ways by means of the uniform language of his neural network, and that every hypertext system has already overcome the limitation of linearity of static written and printed text by direct non-linear access to every part of the text, we are still missing a clear answer to the question of the fundamental unity of knowledge, that is represented in distributed form in different ways as symbols, pictures and sound.

Neither the digital units of machine language nor the isolated data of traditional data processing can be this unit that we look for, but it is the complex structure that has already a high degree of condensation of elementary, isolated information (data) that we traditionally call «concept». Knowledge-based systems are thus always concept-based systems. The missing link between a theory of cognitive information processing and a theory of documentation and of knowledge transfer is, therefore, ***concept theory.***

This theory is also the core of a general theory of learning that links cognitive information processing to documentation and knowledge transfer. For the concept is both, a complex condensation of information in the form of a reaction schema of living organisms, and a fundamental unit of human knowledge that is presented in descriptive concept systems and in causally explaining and prognostic systems of propositions, where the concept appears in its logical function as the predicate of possible propositions.

In this sense we will have to focus ***on basic terminology research*** in the future, in particular on the different possibilities of expressing concepts that are not necessarily expressed by linguistic means alone or that sometimes are presented mainly by non-linguistic means, as it is the case in multimedia systems.

MARKETING KNOWLEDGE AND MARKETING SKILLS TRANSFER IN THE FIELD OF STEEL PRODUCTS MANUFACTURING OF PROFILE AND BRAND PRODUCT RANGE

V.A. Osadchy, E.G. Shmurigin, N.A. Korotchenko (Russia)

For the first time in Russia a unique database developed in the field of ferrous and non-ferrous metals and alloys by the team of the experts of Moscow Institute of Steel and Alloys. The priority feature of the above base is as follows. It constitutes a wealth of various information on metals in CIS countries. The database can replace hundreds of reference books, standards on metals and alloys products, and factory catalogues, including the complete schedule of manufactured products. At present, the size of the above database is as much as 1500 Mb.

The database is intended for fast and automatic search of the manufacturers of any kind of production (rolled flat and structural shapes, pipes, wire, bars, semi-products, ferroalloys, powders etc.) in CIS countries (address and telephone numbers of the managers are included).The database provides information on chemical composition of 6700 domestic and 16000 foreign brands of ferrous and non-ferrous metals and alloys, on correlation in chemical composition for foreign and domestic brands of metals and alloys, on physical and mechanical properties of metals and alloys, on 8000 Russian and foreign standards, on equipment performance at various enterprises, and on production being manufactured more than 600000 positions).

The above systematised database is used for training of students on the following specialities: "Research, development and thermal processing of metals», «Processing of metals by pressure», «Designing of technical and technological complexes». For future experts it provides possibility for quick search of interesting information which can be obtained as a hard copy. The work with the base not only improves the quality of knowledge mastered by the students, but also considerably simplifies and accelerates search for information, increases the skills in the field of information technologies implementation. Future users of the above database are as follows: experts of departments of provision, of marketing, of factory laboratories, as well as managers of selling-purchasing commercial companies, specialised on metal.

The first part of the programme complex comprises a block of the programmes for updating. It is intended for information amplifying and eliminating defects of the above database. The stored information to be updated is as follows: and corrections of the stored information: the list of materials, the list standards, the list of shape product range, graphic representation of the shapes, addresses and payment essential elements of the enterprises, the list of production being manufactured and telephone reference book. The corrected information can be sorted according to on various attributes. The process of information input and the editing is improved through menu application within all textual positions.

The second part enables to execute search, to extract from the above database any bit of information according to user's wish, to output necessary information as a hard copy or as a file for checking, editing and subsequent printing. The user has an opportunity for modify the list of information output and its sequence according to his requirements. When the modifying process is completed, the tables are automatically organized according to paper sizes, the list itself and the schedule of information output. The information can be classified according to various parameters. The list of materials contains definitions and the names of the materials and their groups, codes as to qualifier, material functions, products made of it, and also chemical composition, mechanical and physical properties. Any block of the base allows .search for the suppliers of the material, for information on its properties, on standard requirements and on the list of products under this standard, the list of the major standards. Besides, it is possible to get systematised selected data on product quality requirements. The user has opportunity for carrying out of comparison between foreign and domestic steel brands as to its chemical composition and for selection of a required analogues according to its mechanical characteristics. Shape product range contains the list of shapes supported by the data on materials, standards, modes of manufacturing and sizes. The shapes can be represented as technical drawings on PC display. The list of the information on enterprises includes addresses and banking data. Production of the metallurgical enterprises can be obtained in two modes: brief mode and detailed mode. The database also includes reference book of telephone and fax numbers of the chief managers for enterprises-manufacturers and English-Russian dictionary containing 22000 words.

The third part of the programmes package contains service programmes for creation of convenient work environment. These programmes provide possibilities as follows:

- colour scale and symbol sizes modification on a PC display,
- direct editing and information output of the database contents,
- direct editing and output of file structure.

The programmes are developed in the FOXPRO language for a database control system supplemented by C language.

Centre for Information and Marketing under Moscow Institute of Steels and Alloys delivers consultations and information services by means of the above database.

THE PERSPECTIVE DIRECTIONS OF APPLICATION OF INFORMATION AND COMMUNICATION TECHNOLOGIES IN EDUCATION

S.V. Paniukova (Russia)

Exponential evolution of information and communication technologies determines the urgency of investigation of their use in educational systems at various standards and profiles. The education requirements for efficient utilization of information and communication means led up to new non-traditional developments and techniques for teaching of various subjects. Therewith the problems of pedagogical efficiency inevitably faces confront such innovations, since a use in teaching process even the latest scientific achievements did not bring the training upgrading. The radical solution of a task of educational efficiency advancement is connected not precisely with an expansion of capabilities of modern information technologies, but with elaboration and application of didactic and methodological principles in education. Let up put forward the most promising directions of information and communication technologies introduced in a teaching process.

The creation of subject-oriented multifunctional teaching media permits to use multimedia technology, "virtual reality" method and hypermedia system, as well as electronic textbooks and "micro-world" medium. The subject-oriented multifunctional training media are the combination of previously known pedagogical software, which can realize a new idea of creation and application of information technologies in an educational process.

Multifunctional thinning media include the following components:

- extensive databases, required for storage of various information (textual, graphic, reference), involving video material and animation rollers with audio background;
- knowledge bases of educational purpose, involving a model of definite field of a subject, knowledge about the formation of learner's skills and experiences for their use;
- systems of artificial intelligence, realizing the abilities of data accumulation, concerning the teaching results of each learner for selection of individual effects and regulation of skills and habits formation;
- laboratory practical work with a capability of assignment of mathematical model for phenomena and processes studied, with creation of computer model of a laboratory testing unit or an assembly, made out of existing in catalogue ready elements, as well as operation modelling of this testing unit and assembly at monitor screen;
- expert-training systems, forming a learner's model with a diagnostic of learner's knowledge on the basis of experts' knowledge from a subject field on the level of tutor [1,5], and providing the possibility to analyse user's actions, to realize a wide range of teaching effects, to put questions, arrange control and training, to use communications between learners and a teacher, to promote a computer control and so on.

Multifunctional training media permit the following:

- to organize various forms of learners' activity on independent knowledge absorption and presentation;
- to use the whole range of modern information technology abilities in the process of training of various types of training activity, including such as registration, collection, storage, data processing, interactive dialogue; modelling of objects, phenomena, processes; automation of teaching results control, testing and practising;
- to ensure the control over information flows;
- to manipulate with information, to deform the presented information over different parameters, to choose the needed trend of the relevant topic (text, video-topic, graphic, animation, the control of various devices, laboratory testing units and soon);
- to increase the level of emotional perception of learning information;
- to form the ability of self-study knowledge acquisition;
- to increase the learning motivation at the cost of possibility of self-control, personal and differentiated approach to each learner;
- to develop an intellectual capacity of learners.

Multimedia in combination with hypertext constitutes the hypermedia systems. The hypertexts can be provisioned with not only textual, but with graphic and visual information. The practical realization of those systems brought into existence the-electronic books, designated mainly to independent training. The electronic books conditionally can be classed into four sections: encyclopaedic, informational, training and examining [1, 4]. The difficulty of practical realization of elaborated till now hypermedia systems, intellectual training systems, medium "micro-world", electronic books, etc., is caused, first of all, by the fact, that this software is designated mainly for independent training and contain a number of supplementary information and hardly compatible with a real educational process. The programs for self-study teaching are surely needed, but in definite proportion with the rest training program means. Frequently, the essential reduction of didactic capabilities is induced by the fact that most of them are developed by programmers without participation of pedagogues.

Most of those drawbacks can be eliminated through elaboration of subject-oriented teaching media by a team of high-qualified pedagogues, scientists, engineers, programmer and so on. Their creation is one of the promising trends of education development.

The practice of application of teaching-information media, realising the multimedia technology in educational process, allows to make a conclusion on teaching efficiency raise in the expense of stimulation of the greatest number of learner's perceptions; of utilization of various forms of learner's computer operation; of formation of learner's habits, which can't be formed in other computer media; of application of modern means for audio- video information processing. In spite of difficulty of elaboration and realization in educational process of those media a more wide propagation gains the new technology of non-contact information effect - virtual reality, delivering by means of complex multimedia - operational media the illusion of direct entrance and presence in real time in stereoscopically presented «screen world» [5]. The realization of technology of virtual reality in educational process promotes the following:

- formation of skills and habits for activity of designing and modelling of objective world;
- development of image-visual theoretical thinking, that allows to study not only objects and phenomena of our surroundings, but those phenomena and processed, which can not be reproduced in a reality (space flights in time and space, surgical operations, observations for events, taking place at super high and super low temperatures and so on).

The application of communication means, involving the computer networks, telephone, satellite links for various information exchanges between a user and central information database or between users [1, 2, 3]. Therewith the possibility appears to realise the following didactic functions of telecommunications [3]:

- to fulfil the joint investigations together with learners from different educational institutions and different regions and countries;
- to render a consulting assistance to learners and teachers from scientific-methodical centres;
- to arrange the networks of distance education and qualification upgrading of pedagogical staff, to perform an exchange of top-level pedagogical technologies;
- to interchange the information of interest, themes, to use the information obtained for educational and scientific purposes, to analyse and study the foreign experience;
- to form a learner's culture of contact, the ability to formulate briefly and legibly his own thoughts, to sustain a discussion, to prove his point of view, to respect a partner's judgement;
- to form experience of research activity;
- to form an ability to obtain information, to storage, to transit and to process it;
- to promote the mental development of learners.

On utilization of communication a new approach to teaching and education is used, which permits to stimulate an independent learners' work; to develop their intellectual and creative capacities; to operate with various sources of information; to involve them to designing of their own presentation about environment, to form their own world outlook instead of plain ready knowledge absorption.

ON THE HIERARCHICAL MULTIENVIRONMENTAL APPROACH TO THE WORK WITH KNOWLEDGE

V.V. Prokhorov (Russia)

When working with computer technologies, the diversity of existing spheres of application of computers and, respectively, of information-language environments, to which operation in these branches is oriented, presents a great problem. The efficiency of work with computer facilities is directly connected with the fact, to what extent language aids of man-computer interaction are adequate to class of objects, dealt with in the specific branch. The problem of selecting approaches and corresponding computer environments in education is more aggravated in connection with a reasonable wish to give pupils certain relatively long-living knowledge and skills.

Problem of co-ordinating branches of application of computer technologies with specific programme environments is usually solved by one of two methods. The first method consists in studying and using some universal aid and reducing all really arising objects to it. Teaching courses, based on this approach, contain two sections: studying of some universal paradigm (for example, algorithmic logic or functional) with corresponding computer environment (for example, Pascal-system) and studying methods for reducing problems from different branches to this paradigm («programming»). The another approach consists in studying and using some aids, containing a variety of capabilities for work in any particular branch, for example, systems for work with databases. This approach requires studying a relatively great number of sufficiently great specific systems, which comparatively quickly become obsolete. In so doing, a situation of balancing between tendency to a wealth of capabilities of used and studied systems and their simplicity, flexibility and universality arises. On our opinion, the only way to solve the noticed discrepancy is to use a hierarchical micro-context approach.

In compliance with this approach we propose to extract different compact principles of forming composite objects from simple ones, sets of basic composition (decomposition) aids, for example,

- algorithmic aids, allowing to represent some action as a time sequence of simpler actions;
- functional («formula») aids, allowing to build more complex conversions from elementary functional conversions (for example, arithmetical operations);
- logical («predicate») aids;
- «geometrical» aids, allowing to construct graphic elements from the other elements; composition rules, allowing to create complex types of data from simple ones (for example, as in Khoar language in Pascal);
- syntactic rules, allowing to describe composite objects through simpler ones.

Each of these methods can correspond to its micro-language (note, that in such approach the algorithmic language will not contain formula, operators of assignment, descriptions of data). It is proposed to consider any informational description as a structure of elementary descriptions, i.e. the common description language will be formed as a structure of their micro-languages, arising during solution of specific problem.

Note, that such an approach in the «anatomy» form can be applied to already existing languages by selecting micro-languages in them. The described approach permits us during training to independently consider typical paradigms of composition/decomposition for different approaches and different branches (including different sciences). In considering specific object one should skillfully carry out the stage-by-stage decomposition of description with selection of most suitable, paradigm at every phase of embedding. In the presence of special programme aids for supporting this technology it is sufficient for its successful work. For working with traditional environments one should be able to- reduce descriptions in paradigms of the hierarchical approach to descriptions in terms of aids of these environments.

Merits of using the hierarchical micro-context technology are as follows:

- every element of complicated information work is performed in microenvironment, most suitable for work both according to language and to interface equipment;
- every one from sub-environments is very simple in studying owing to its compactness;
- common approach to different information concepts (i.e. in sphere of programming the difference between «algorithmic», «functional», «logic» languages, between «programming» and «employment of complete programmes» is removed);
- ensuring the maximum opportunity to use the obtained knowledge owing to skill in carrying out division of any language into micro-levels, extracting known elements in arbitrary systems;
- even slight set of different sub-environments creates considerable diversity and power of specific environments, hierarchically formed by this set.

Thus, the use of this technology permits, in particular, to settle the problem of discrepancy between simplicity of information environment and a wealth of graphic aids, provided by it.

For some years the author lectures the special course «Models and Languages» at the Ural State Technical University, based on studying basic micro-aids and also used this approach in lectures for school pupils.

Programme complex PIFAGOR for IBM PC-compatible computers is an example of realization of the programme environment on the basis of micro-language hierarchical approach. The complex contained algorithmic, formula, syntactic micro-language layers (aids for their edition, compiling and execution). Used as operators of algorithms can be arbitrary external environments (for example, graphic, text, music editors, environments of logic or functional programming, aids for work with external devices, for carrying out physical experiments, etc.). The specific feature of the complex is employment of graphic languages, visual descriptions.

The complex can be used for realization of the main principle of hierarchical technology: each type of information should be represented in the most convenient form; preparation of programme should be made by most suitable means; processing should be accomplished by most suitable equipment.

The complex can be used in training process as «world», in which the trained person works and also as an environment, in which training environment can be developed. In this case, one may employ already existing (in arbitrary computer representations) text, graphic, music materials, existing already-done works in the form of programmes on arbitrary languages and maximum use of accumulated-by-used experience in operating any computer systems, and also arbitrary auxiliary equipment (scanner, sound input, tele-camera, power-driven models, etc.) with the simplest procedure of its connection. It allows us to quickly develop programme systems, multi-language systems, having a minimum level of familiarity with computer and with complex PIFAGOR.

During operation in the algorithmic environment a triad concept «developer-manager-executor» is realized. Works connected with each of these elements look differently, «manager» and «executor» correspond to different windows on the screen, activity of «developer» is based on its own window of icon menu.

To increase the interest of work diagrams of algorithms in the system are represented with the use of various showing metaphors. During edition and performance of instructions sounds and animation are widely employed. This has done, activity on developing and debugging the programme outwardly reminds a game. The accumulated experience of work with complex PIFAGOR of children, beginning from 5-6 years old, shows, that they really perceive this work, as an interesting game. In the same environment the development of the other sufficiently complicated programme environments is implemented.

TV-COMPUTES INFORMATION TECHNOLOGIES AND DISTANCE EDUCATION

I.N. Pustynsky, Yu.P. Yekhlakov, M.I. Kuryachy, V.V. Kruchinin, O.V. Ravodin (Russia)

Permanent improvement of information technologies results in the growing number of higher educational establishments using these technologies in the process of teaching. Alongside the computer technologies, TV-computer information technologies are being increasingly applied of late, using extensively TV means of data transformation and transmission.

In this communication the findings and experience of Tomsk Academy of Computer-Based Management Systems and Radioelectronics (TASUR, Russia) in this area, as applied essentially to distance education, are set out.

The technical facilities for distance education at TASUR include:

- Corporate Computer Network of the Academy «CCN-TASUR» [information and communication units in three academic buildings, local computer networks (LCN) in these buildings, local computer networks and distant terminals of the academy branches];
- TV-computer system with equipment for putting together and transmission of «Tele-text» programmes and of computer data via TV communication channels;
- transceiver complex of satellite television.

The primary component of «CCN-TASUR» are information-communication units, providing for integration of the local network subdivisions into a universal information space and serving as a gate to «CCN-TASUR» and global networks. Every unit has a file server managed by OS Novell Netware 3.12; a communication UNIX-system managed by OS UNIXFreeBSD 2.0.5; teaching UNIX-systems managed by SCO UNIX.

A communication UNIX-system provides for interaction of «CCN-TASUR» units among themselves and with the units of other networks, and functions as a gate between LCN of each building and other networks having access to Internet.

In addition to the listed functions, one of the information-communication units secures the functions of external interaction with other networks. The unit has a modem for remote access through switched communication lines; marked channels of ucban information medium; IP-channel for Novosibirsk and Moscow; «Iceberg» equipment of «Inmarsat» system with a telephone satellite communication channel; a unit of international non-commercial network FIDO. Communication between information-communication units is arranged in three options that duplicate one another: via a marked telephone communication channel through short modems based on a family of TCP/IP protocols; via a radio channel, at a speed of 10 MB/s; via switched telephone communication channels, using standard Hays-modems on the basis of the UUCP protocol.

The internal LCN network infrastructure comprises two levels: inter-server segments of the local network connect the servers of subdivisions and of the departments network class-rooms. All local networks of an academic building are based on Internet and support IPX/SPX and TCP/IP protocols.

At present, there are 25 local sub-networks of «CCN-TASUR», the operating stations being equal to around 320.

Now that a platform of technical programmes for a multitude of information resources to back the teaching process is created these can be used effectively on a large scale to meet the requirements of the teaching process, in particular, to organize distance education. The following facilities are available, among other things, to the user of local networks (providing access is properly authorised):

- access to all file- and UNIX-servers in LCN;
- work with electronic mail (local, within an academic building, and global);
- operation through Internet and FIDO gates;
- using ETELNET protocol to connect a distant terminal with any UNIX system within the local network or in Internet;
- operation in FTP mode: to be able to exchange information (data files) with subscribers having access to Internet;
- operating NET BBS as a convenient means of organising a paper-free training process technology;
- using a multimedia distributed reference system based on a WWW-server.

If the end users have an adequate supply of hardware and software resources, WWW-technology is an excellent structural nucleus of the distance education system as it exceeds quantitative and qualitative characteristics of BBS.

External (relative to LCN) electronic communications available to remote subscribers in the distance education system may be divided into three categories:

- those using Internet capability and protocols (telnet, ftp, WWW, Net BBS);
- those using FIDO-NET network mail;
- those using direct modem connections via switched telecom lines (backing of the UUCP protocol).

The choice of one of the options of an electronic communication channel is made by the student, depending on his technical capability, while the potential of TASUR communication units make it possible to maintain all the aforesaid categories of communication on the basis of equipment available. In terms of the diversity of capabilities and accessibility of all protocols and communication technologies (including WWW), work to IP protocols is preferable. Once a subscriber has an access to the presumably free FIDO network, he can use FIDO E-mail facility to exchange information with the teaching institution over any distance. Using a direct modem connection, the user is free to work with a network training BBS, engaging its modem input, and has a reference system at his disposal, along with a possibility of dual transmission of data files.

Transmission and reception of educational information in the system of distance education, using air and cable television, constitutes a relatively independent use of this technology. In this case, a student may have access to information on teaching programmes when it is broadcast via telephone networks in a desired mode, via air television in the form of particular tele-text programmes transmitted together with ordinary tele-programmes or in the form of video films. The use of a conventional TV-set connected with a source of information being part of an information-communication unit, makes it possible to produce an interactive mode enabling a student to communicate with data and knowledge bases, which become optionally accessible through a feedback in the system.

System configuration comprises equipment for putting together and transmitting a tele-text programme and computer data, a local computer network, an editing video studio, a computer graphics studio to produce and broadcast multimedia programmes in the «Invision» mode, TV cameras for recording and archiving fragments of training courses, and a network of TV-sets with a system capable of receiving additional textual information of tele-text type. Information may be transmitted to subscribers' TV-sets either via a cable network or in an air broadcasting mode (with feedback via telephone channels).

The system integrates the strong aspects of television, computer engineering and up-to-date methods of teaching, and provides for the following functions of distance education:

- regular educational TV broadcasts for schoolchildren, students and for self-education, using the bank of video materials available in Russia;
- holding preparatory extra-mural video course for those willing to enter institutions of higher education;
- holding discussion, advertising-information and other TV programmes on scientific and educational issues;
- putting together and broadcasting reference, methodological and scientific-educational information blocs for population and organisations over the «Tele-text» channel.

At present, in Tomsk, TASUR specialists, in association with an independent TV company «TV-2» have launched an UHF-band TV channel (22nd channel). On the basis of this channel, an equipment-and-software complex has been developed to transmit additional information (tele-text programmes and computer data) via television communication channels. Since early 1995, transmitting equipment has been operated on two Tomsk TV channels. The complex in question transmits the data at a speed of up to 100 kb/s.

The transceiver satellite TV station provides for reception and transmission of a television signal from satellites with geo-stationary orbits. It comprises a very sensitive receiver, a 1.5 kW radio transmitter and a parabolic antenna of 4.5 m in diameter.

The system of distance education combines the basic principles and approaches of extra-mural education with elements of day-time education. Emphasis is placed on independent study of subjects by the trainees. However, for all the apparent similarity, the proposed training technology is fundamentally different from extra-mural education. This is manifest in that the user is in a position to maintain permanent contact with an institution of higher learning, to consult a lecturer quickly should a problem develop, whereas the lecturer can, anytime, monitor the results of trainee's independent study.

Here, two major problems of organizing the training process should be distinguished: institutional and methodological.

Institutional problems consist in synthesis of the specific system of following up the performance of trainees, in synthesis of the structure and algorithms of distance education functioning, providing the most optimum conditions for the trainees as well as for the lecturers. Of crucial importance here are matters of administration which stipulate the performance of functions aimed at reliable and efficient distance education.

The methodological problems of distance education organizing comprise the development of information technologies, performance of teaching process and creation of corresponding information resources. For these purposes, TASUR has developed a workbench system [hereinafter referred to as FEYA ('Fairy')], intended to produce all kinds of teaching software (TS): computer text-books, practical courses, tests, examiners, etc.

The system's functional structure includes:

- vector-type graphics editor for entering and editing graphic teaching information with a possibility to include pictures of PIC and PCX formats;
- paragraph text editor, working in a graphic mode, with a possibility to change paragraph position and size, line space, word font and colour, to format a paragraph, to import text files produced by other editors;
- menu editor;
- editor for producing questions and entering benchmarks;
- editor for management entities designed to organize all kinds of cycles and transitions, depending on trainee responses or a choice in the menu;
- music editor;
- configuration programme;
- executing model.

In terms of methods of teaching, TS in the «FEYA» system is a combination of interrelated frames. Each frame consists of a fixed set of entities: graphic, musical, management, etc. (in all, nearly 80 types of entities).

The aforesaid technology of TS development has been adopted at TASUR and has been transferred for adoption to a number of institutions of higher learning in Tomsk, Novosibirsk, Krasnoyarsk, Abakan.

The results presented in the article determine only the initial stage of adopting TV-computer technologies in support of distance education. In our view, the following are priority areas of further research: adoption and adaptation of WWW and BBS technologies for distant access to information resources and programmed systems in support of the teaching process; increasing the rate of «Tele-text» programmes transmission; development of institutional-and-methodological aspects of organizing RE, of building up information resources in particular areas of training, trades, subjects.

VIRTUAL REALITY SYSTEM IN EDUCATION: DIDACTIC PROBLEMS, PROSPECTS OF APPLICATION

I.V. Robert (Russia)

The virtual reality is a new technology non-contact informative interaction, realizing by means of a complex multimedia-operational media the illusion of a direct entering in real time and presence, concerning with stereoscopic «screen world». The non-contact technology of information interaction, realized by the system «virtual reality», makes it possible for computer to reflect in digital form the pulses from «information globe» («interface-globe») and «information suit». A user can, figuratively speaking, make «a step» directly to virtual world, if «information suit», «information gloves» and «informative spectacles» with firmware spectroscopic screen (spectacles-telemonitors) are available.

Just now the capability of «virtual reality» systems are used for training of sportsmen, for preparation of future specialists in airspace, architecture, medical diagnostics, for arranging the entertainment and a rest, and, also, in areas, using a scientific visualization (for formation of illusion of actually conducted medical operation).

The basic components of a typical system «virtual reality» are follows:

- the enumeration's or lists of objects, forming a virtual world, in a subsystem of creation and management of objects of virtual world;
- a subsystem, recognizing and estimating the state of objects and creating permanently the picture of user's «location» relatively to virtual world objects;
- head-installation display (glasses-terminators) with continuously shagging pictures of virtual world «events»;
- a device with manual control, arranged in a form of an «informative globe» or a «space ball», indicating the direction of user's «isplacement» regarding to virtual world objects;
- a device for sound formation and transmission.

The contact of user with a system «virtual reality» can be realized by voice or with a special device-joystick, providing a feedback as well as with the glasses-terminators. Separately, let us observe the last devices, since an audio communication is not new, in principle, and is used for a long period of time. This should be noted, that the reaction in the system «virtual reality», to audio signal, received from user, is reduced in accordance with prescribed program.

The device joystick causes the effect of force-feedback communication, and «interface-glove» enables gesture contacts, converting each movement of hand into an electric signal, which are perceived and decoded by means of a computer. For example, while manipulating by fingers in «informational glove» in front of a screen, one can move the objects on screen. Moreover, it is possible to «enter» into virtual world of screen, removing, replacing and touching the objects, depicted on a screen. Thus, for instance, one can feel sphericity of a globe, an illusion of grasping an object, depicted on a screen, «sense a weight» of this object. The glasses tele-monitors provide a stereoscopic vision of screen representation of virtual world. The modern system «Virtual reality» usually ensures the creation of various «pictures» for each eye. Under some displacement the user is able to «overview» by all means of tele-monitor the whole stereoscopically presented «picture» of virtual world.

The special «informative suit» is used for a perfect, polyhedral and multifunctional, non-contact interaction of user with the virtual world. It should be noted, that software realization of «Virtual reality» has different variants. Schematically, the presented above description is a one of possible.

At present time, three approaches can be singled out for a realization of user's interaction with the objects of virtual world formed by a system «Virtual reality».

The first approach realizes the idea of «immersion» into virtual world. Therefore; figuratively speaking, a user, dressed in informative «space suit», «enters» in digital universe. Manipulating with a «informative glove», he directly interacts of virtual world, represented on a screen, «moves» or vflies» in side it, in fact, with synchronous audio background.

The second approach provides a window presentation of three-dimensional space of virtual world on a computer screen. Therewith as a means of control the devices of a type of «space-ball» or «flying mouse» are used a significant degree of freedom.

The third approach realises an interaction with the objects of virtual world through the «third person», presented by a moving image on a screen (for example, in a form of some drawing), and identified with a user himself. Therewith the actions of a third person are controlled by a user, as if finding his image on a screen. All these approaches realize the main idea of informative interaction, enabled by a system «Virtual reality». This idea consists of providing, firstly, of a direct user's participation in the events, taking place in virtual world, but acquiring in real time, and, secondly, with maximum distance of interface between user and a computer.

The realization of mentioned above possibilities allows to create a principally new level of informative-subject medium of «immersion» into three-dimensional, stereoscopically presented «Virtual reality», providing the following:

- modelling the senses of direct user's contact with objects virtual reality (to see, to hear, to touch by hand);
- non-contact user's control with objects or processes virtual reality;
- imitation of reality - the effect of a direct participation in processes, taking place on a screen, or influence of their modification and functioning;
- interaction with objects or processes, having their image on the screen, the realisation of which is impossible in actuality.

The capabilities of a system «Virtual reality» through realization and introduction of special methods of «imbedding» of training technologies into subject-oriented training media allows to realize a teaching affect of longitudinal character, providing the following:

- the development of visual-mapped, visual-active, inductive, creative, theoretical thinking;
- the formation of aesthetic tasks, evaluations, promoting to aesthetic education.

The use of system «Virtual reality» opens new methodical possibilities along with formation process:

- skills and habits of subject world projection;
- skills and habits of artistic activity - «activity», along which an artistic composition is originated and accepted;
- abstract images and meaning, presenting to a learner an instrument of modelling of studied objects, phenomena as environment, and of those, which are unproduceable in reality.

The realization of capabilities of «Virtual reality» system is combined by the level of software development, created for functioning of «virtual worlds», and capabilities of instruments.

NEW INFORMATION TECHNOLOGIES IN TEACHING: A PSYCHO-PHYSIOLOGICAL APPROACH

M.E. Sandomirsky,
L.S. Belogorodsky,
T.A. Baumshtein (Russia)

The main directions of a psycho-physiological approach to application of new information technologies (NIT) during teaching are:

1. Improving the efficiency of training owing to creation of optimal functional states, enhancing the faculty of brain for mastering information - i.e. a psycho-physiologically-oriented teaching. It is based on employment of known neuro-physiological mechanisms, being the foundation of processing the information by brain, thus providing the more complete realisation of brain potentialities for training. Just the computer technologies create the basis for introduction of similar training methods due to opportunity of using a computer during a session of interactive training besides implementation of the main training task in the background mode for solving the problem of controlling the functional state of a trained person and for individual physiologically-substantiated measuring of information load depending on this state.

This work cover the following two methods of psycho-physiologically-oriented training:

a. formation of artificial sensitive periods (ASP) for improving the efficiency of mastering information during training of adults, juveniles and children of older age groups (using the phenomenon of hypermnesia, creating the motivation for mastering knowledge);

b. controlling the formation of mental strategies for accelerating the intellectual development (developing training), when training children of younger age groups (using the laws of age maturing of the functional asymmetry of cerebral hemispheres).

2. Neutralization of the adverse affect of NIT on the trained person. In particular, when using NIT during training of children - preventing of their possible adverse affect on formation of the functional asymmetry of cerebral hemispheres and mental development of a child.

Owing to their purposeful effect on dynamics of inter-hemisphere relations the described training methods (a, b) help also in solving this problem.

I. FORMATION OF ARTIFICIAL SENSITIVE PERIODS ON THE BASIS OF VIRTUAL REALITY TECHNOLOGIES

On of proposed methods for improving the efficiency of training with NIT applied is modelling of natural functional states, appearing in definite age periods and connected with improved ability for perception and storage of information - so called sensitive periods or periods of increased sensitivity for development of certain mental functions.

In earlier work (Sandomirsky M.E., Belogorodsky L.S., 1996) we shown connection of age dynamics of sensitive periods with stages of ontogenesis of the functional asymmetry of hemispheres, allowing to form NIT with the aid of physiological age regression, i.e. to recreate the inter-hemisphere relations peculiar to younger age periods, in particular, with activation of the subdominant hemisphere. In this case, reproduction of the functional state, returning the brain to previous stages of its ontogenesis, i. e. to physiological age regression, improves the efficiency of mastering information, activating «early setting for training» (M. Erikson, E. Rossi, 1995), formed in childhood. In similar state the incoming information is assessed by brain as a statistically rare and high-information one, being of great importance for organism, and the efficiency of its storage is, respectively, increased. Temporary change of brain to the functional state, peculiar to younger age period is considered, on one hand, as an artificially crated period of sensitivity and, on the other hand, as the changed state of consciousness (CSC). Passing through the similar state is the obligatory condition of efficient training [it is considered that in principal any mastering of material during training is implemented in short-time periods of CSC (S.Heller, T.h. Steele, 1987)].

State close to described aoove can be formed spontaneously in the course of the man-computer dialog, *creating the background state of readiness for transition* to CSC or the superficial CSC. Correspondingly, on the basis of these states the «utilitarian» CSC can be formed for improving the mastering of training material. To prove this thesis, first list the basic factors of CSC induction:

- concentration of attention;
- *artificial organization of a sensor environment, breaking* usual stereotypes of perception (including sensor deprivation and sensor overload);
- paradoxical content of incoming information, bringing to forced refusal from thinking stereotypes, when during search of problem solution the logical way does not lead to the proper results; thinking procedure, going on the sub-consciousness level, are respectively activated.

What factors from those, favouring the cause of CSC, take place in using computer information technologies during training? When discussing this problem, it is necessary to select two classes of problems, occurring during operation on a computer, which require either (I) standardized activity - mainly of operator type, connected with working-out of senso-motor operator skills (keeping of attention, rate of response) or storage of routine information; or (II) original activity - analytic work as well as solving of creative problems.

It is clear, that all three factors of CSC induction arise naturally in the course of man operation with computer. First, it is the factor of concentration of attention and also artificial organization of sensor environment - either elements of sensor deprivation (motionless pose, fixation of sight, sensor monotony), or (more often) sensor overload. In so doing, in problems of I type continuous concentration of attention is achieved owing to continuous change of situation, while in problems of II type concentration of attention in linked with the third factor of CSC induction. In this case, the latter occurs in the form of stressed intellectual activity, especially in case of troubleshooting or available discrepancies (cognitive dissonance according to L.Festinger).

The above-described data results in the fact, that in case of using NIT during training we can often observe during man-computer dialog the spontaneous development of CSC, in a number of cases sufficiently deep and intensively felt. In this case, User may not interrupt his work on computer for many hours. If we consider the extreme displays then lovers of computer games can be a well-known example for problems of I type and programmers-«hackers» - example of problems of II type. On one hand, arising of such states visually demonstrates the possibility of intensive effect of NIT on the functional state of man, including the state of consciousness; on the other hand, practical employment of similar spontaneous non-controlled CSC for intensification of training seems impossible.

At the same time it is obvious, that, using technical potentialities of computer (especially multimedia) in the course of interaction of man with computer, one can organize the information flow, acting on man in such a way, that to maximise the specified factors of GSC induction. Thus, controlled CSC can be formed and used during training for improving its efficiency. For this purpose, it is expedient to use, parallel to feed of training materials, the technology of programmable rhythmic audio-visual stimulation on the basis of multimedia facilities, presenting a variety of virtual reality technologies. The essence of method consists in synchronization of endogenic biorhythms with rhythmic variation of an external input signal, thereby implementing their modulation. It enables to carry out the purposeful formation of both frequency and space pattern of brain bio-electric activity, thus allowing reproducing specific functional states - ASP, required during training and optimal from the point of view of its efficiency. It is advisable to perform the diagnostics of these states and the physiological inspection of their running either by monitoring the EEG or by carrying out the statistical analysis of heart rhythm and, firstly, its spectral characteristics (N.N. Danilova, 1992). According to monitoring data this procedure includes not only inspection of CSC depth, but also operative •measuring of information load in the on-line mode. The indicator of the depth of created CSC and corresponding ASP in monitoring the bio-electric activity of brain is dynamics of the functional asymmetry of hemispheres, undergoing a number of stage changes in order, inverse to order of its formation in ontogenesis:

1. Offset of activity focus within the hemisphere, accompanied by change of the leading perception modality or the representative system, including transition to rarely used «displaced» systems.
2. Inversion of the functional asymmetry with activation of the subdominant hemisphere.
3. Levelling of the functional asymmetry with smoothing of inter-hemisphere differences.

II. STIMULATION OF INTELLECTUAL DEVELOPMENT BY INDUCTION OF MENTAL STRATEGIES

From positions of a psycho-physiological approach individual differences in methods of processing and mastering information during training are based on preferable mental strategies, formed in the course of ontogenesis (M.E. Sandomirsky, L.S. Belogorodsky, 1996). The mental strategy can be considered as a system of priorities of activating different brain zones, characterised by a specific information processing method, determining the priority of including them into procedure of its processing (Sandomirsky M.E., 1995). Application of NIT during training for children of young school age can, on one hand, allow us to accelerate the maturing of strategies and, on the other hand, enhance the intellectual potential in subsequent age period. The latter is possible owing to mastering of related strategies together with a basic individual-typological strategy. In case of usual running of the age development process the individual-typological strategy, formed in the school age, is often a single one, while the related (alternative) strategies are simply inaccessible. In some sense, the leading formation of mental strategies is equivalent to solving the problem «how to teach learning». Accelerating the formation of strategies can be provided by employing the method of purposeful working-out of mechanisms for random inspection of cerebral activity patterns with the aid of adaptive bio-control (ABC).

At the initial stage the method proposes to conduct procedures ABC, first employing the visual channel on the basis of showing pictures of spatial distribution of electric activity of brain. Working-out of strategies includes several stages.

1. Creation of basic functional states considered as strategy elements. For this purpose, a habit of arbitrary bio-control for electric activity of brain (static mode) is elaborated for a trained person with creation of a stationary activity in the specified cortical zone. Every basic state should be connected with definite stimuli - «armatures» of different modality, poly-sensor ones being desired (which activate the right-hemisphere mechanisms of perception). At first, an external stimulus is used, then - with the automation of habit - transition to endogenic stimuli (visual, audial, kinaesthetic) takes place. One can say about generation of sensor-neuro-dynamic associations, deflecting connection of certain signals with internal states of brain (according to N.N. Vasilevsky, 1970). As practice shows, the adaptive bio-control helps to achieve stable reorganization of EEG-activity patterns and, respectively, the random inspection of definite functional states, the similar training of children running quicker and bringing to more stable results.
2. Creation of complex functional states on the basis of 4-element combinations of a set of basic states - movement of a focus of maximal cortical activity in the specified sequence. Teaching the habit of arbitrary switching, alternation of a definite combination of basic functional states - first, in 2-step, and then in 4-step sequence - practically presents the mastering of the mental strategy, corresponding to the given combination of them (at all 16 alternatives of individual-typological strategies are considered).
3. Interiorization of habit, elaborated in item 2, i.e. formation of ability for independent reproduction of the complex functional state (strategy) in different situations, not based on hardware components, ensuring ABC.
4. Practical development of habits for using strategy during mastering of training material and solution of training tasks.

III. NEUTRALISATION OF ADVERSE AFFECT OF NIT ON DEVELOPMENT OF TRAINED PERSON

When we say about negative moments of applying NIT during training, especially during work with children, it is necessary to mention about potentially adverse affect of computerized training not only on the current functional state of a child (action of electromagnetic fields, visual fatigue, monotony, hypo-dynamics), but also on its mental development.

It is known, that intensive and long-term studies of child with computer, connected with predominance of logic left-hemisphere method of information processing, are thus linked with preferential formation of habits of left hemisphere. The latter can lead to unbalanced formation of the functional asymmetry of hemispheres owing to one-sided development of habits of the left hemisphere to the detriment of right-hemisphere ones, and consequently to one-sided and non-harmonious development of child psychics, to deformation of its development, appearing, in particular, as a deficiency of commutative habits, auticity. On our opinion, application of specified methods for controlling the functional state of a trained person in the course of training procedure with NIT employed, in particular creation of states, connected with activation of right hemisphere (ASP), can not only provide the improvement of the training efficiency, but help to overcome possible negative psychological aspects of training computerisation. The latter is the subject of further investigations.

THE TEACHER AND NEW INFORMATION TECHNOLOGIES. NATIONAL AND REGIONAL ASPECTS

A.L. Semenov (Russia)

The approach to the information technologies (IT) use in Moscow region schools is described in the report, meaning precisely that teachers are the key factor for educational changes, and which should realize all advantages of information technologies.

At present time Russian regions are responsible for financing of educational system and for some extent, for basis curricula. The Moscow city stays in favourable position owing to persistence and sequence of its authority. The Moscow Committee of Education supports the wide variety of educational systems in scope of the fact that schools have to adhere to a number of federal and regional limitations and norms. Moscow standards of education are under elaboration now: they are structured like hyper-structure of knowledge and minimal requirements. To recent days the Moscow region occupied the leading position in Russia regarding not to the extent of schools fitting out with technological means, but to a real involvement of teachers into educational process.

Ten years ago the mandatory training subject «Informatics and computing» was introduced (with participation of the reporter) to all Soviet schools. At the time the basic concepts were embedded for next decade. And also from the beginning it was declared on the existing of three branches of school informatics. These are the mathematical informatics, the study of information technologies and application of information technologies in educational activity for other school disciplines.

In Moscow standards of education, which are now under elaboration, the theoretical informatics is being combined with mathematics, and information technologies enter in educational area «Technology», filling more than 50 % of its training time (2 hours per week for 1- 9 forms, 3 hours/ week for 10-th form) and can be introduced additionally in regional, school and personal component.

The educational area «Technology» is organized by module principle. As a rule, each module shows to pupils the range of practical use of the studied content in terms of modem and future actuality, considering it as a part of cultural inheritance and also the ways of its utilization in study of other school subjects, fulfilment of training projects and, at last, as an educational technology (compositions and text editing, arranging and filling the data bases, creation and presentation of hyper-textual structures, scientific observations, data collection, conducting experiments, communication and mass-media). At the same time many of modules were oriented on formation of general concepts (such as, for example, tool, friction, assembling - dismantling, classification, understanding of main types of formation and its search; activity planning and cooperation; aesthetic, ecological and economical aspects of technology). As for information technologies, they especially readily enter in such new Russian school-training subjects as *«Citizenship Studing»* and *«Moscow Studing»*. According to the projected approach the children interview the members of .their families, old residents, chiefs and then decode, edit and resume texts, thus, it easy to understand, what is the difference between such kind of educational activity and standard dictations and presentations.

Today Moscow schools are equipped not only with computers (on the basis of INTEL and Apple plus the obsolete old Soviet machines), but the information medium is created there, integrating all types of information: digital data, text, graphic, audio, video, system input devices (cameras, microphones, scanners, sensors, transducers and so on) and system output devices (monitors, copy-mashies, printers, head phones, synthesisers and so on); designers sets (LEGO), modems. The unique computerized apparatus are used for operative observation after pupils' health. To raise its technological instrumentation, a school makes a substantiated application, which, in fact, helps a staff to understand better their own aims and the ways to them. The application is inspected by the Expert Council on new technologies under the Committee of Education.

Now computers are not locked beyond iron doors being in power of only one teacher of informatics. They are used by teachers of other subjects, school administrators, and librarians. A teacher needs to know that in this case the main necessary skill is to master the blind method of printing. The important organizational scheme of information technology introduction into the net of various subjects is based on co-operation of the two teachers: of definite subject and technology. Working together they present to pupils the opportunity to master the technology as a subject and to apply it right on-the-spot.

The intellectual potential of former soviet academic, applied, military and industrial sciences is Russian tradition of direct participation of famous scientists in school development (well-known example of A. Kolmogorov). The Institute of New Technologies for Education (INT) established by Moscow Committee of Education, is an organization, co-ordinating this process. The examples of other structures, representing the same potential, are the magazine «Chemistry and Life», Interdisciplinary correspondence School, Moscow Institute of qualification upgrading of educational workers, responsible for retraining of teachers and providing the technological support.

The various combinations of instrumental and software means permit to form the training and developing media of most different destination. Thus, the universal design, introducing a child into a sphere of material design, is a LEGO, while into a computer design is a LOGO. The most mass in the world training software, adapted by INT to Russian school, is product - LOGO that is most popular in Russia. Among most recent LOGO-versions the Russian schools use *LogoMiry*. Recently INT had completed the elaboration of FirstLogo - *Logo* without words. This Logo version, connected directly with *LogoMiry*, shows an excellent property - one can use it, being unable to read and to write, even knowing no alphabet. On the contrary children, when using it, master an alphabet, digital and algorithmic competence. Among other INT that are developments in theoretic informatics are the following: «Algorithmics» is a textbook and problem book for 5-8 forms, approved by Minister of Education of RF; «Mathematics and Language» is a faculty course for junior school and kindergarten. The software now in school use also includes the general applied packs of common use, such as «computer designer sets» («Live Geometry», «Live Physics»), mighty combinations of two those families - Logo (*LogoMiry* and FirstLogo), hyper-encyclopaedia on CD-ROM and the access to Internet sources. We treat Internet, first of all, as a form of alternative and non-formal training. At the same time Internet can become an instrument, assisting the pupils to collect research data for international training projects; to participate in routine teleconferences for students and instructors, devoted to one or another school subjects and delivered by world-wide known scientists. Along with such course of events some students can act as expert - consultant on one or another theme in their school. The strategy of information technologies introduction into education uses also the meaning of «zone of nearest evolution» for school (Vygodskie's metaphor) and building up a community of teachers and instructors, exemplified by the Moscow Club of teachers «Technology».

In such educational situation the importance of the teacher significantly increases and his role changes. Now during the curricula he can play the role not only of a person who knows how to answer the questions and who evaluates students' knowledge but also the role of a scientist - this role we offer to the students -the person who is like a baby always ready to investigate surrounding World.

OPEN «EDUCATIONAL ARCHITECTURE» FOR THE INFORMATION-AGE SCHOOL

A.Yu. Uvarov (Russia)

As in many. other countries, schools in Russia are in the process of deep transformation caused by intensive informatization of the economy and society's life generally. The continuing informatization of education implies serious changes in the substance of the methods and organizational forms of general secondary education at a stage when the school is learning to live in an information society. Giving an outline of the situation, one may say that there has begun practical transition from education against the background of limited access to information to education against the background of unlimited access to information.

In the context of advancing information society, global control over access to information is unfeasible. Free access to the entire wealth of information amassed by mankind is an inalienable right of every citizen. This right is not merely declared but is practically supported by the modern electronic information means, computers, the Internet global infrastructure. To teach the children to live and work with confidence in this ever-changing environment is a new challenge to the secondary school. And this means that the teaching methods and forms should be constantly changing to the extent to which they contain the elements of the new substance of education.

The updated substance of education with the computer equipment supporting this process is becoming the foundation of all «new-generation school curricula» which should be offered to the modem schoolchildren, these future citizens of information society. However, it is not always realized that the principal brake on this process is the long-established organization of secondary education, the traditionally rigid «architecture of teaching».

Obviously, the school has no other alternative than to radically revise the substance, methods and organizational forms of teaching, to introduce new information technologies as the chief instrument of the change of the information environment inside the school itself, to adopt an open «teaching architecture», and to gain an awareness of itself as a participant in the global educational process. These tasks have already acquired a practical aspect. It is necessary to show the ways of creating an open «teaching architecture» which would naturally integrate all the information technologies applicable in secondary education; of helping schoolteachers to discard the methods typical of the closed «teaching architecture» and purposefully learn to employ the whole range of the methodological and information means offered by an open «teaching architecture».

Such an attempt was made within the framework of the research project «*The World Around Us*» [3]. Developed as a result of a three-year teaching experiment, the course «Natural Sciences-5» (NS-5) is an example of how a subject long-established on the school curricula was adapted with a view to preparing schoolchildren for life in information society. NS-5 was to replace the «Nature Studies» course, which forms part of the fifth-graders' general secondary school curriculum [4]. The new course is based on:

- the experience of teaching the natural scientific disciplines and using the «research» approach in education accumulated in Russian schools;
- international experience in drafting curricula for the 21st-century school;
- original programs for the use of computers, training programs and telecommunication means in secondary education.

The overall purpose of the course is to introduce schoolchildren to the natural scientific research methods. Laboratory and computer classes, homework and participation in conferences familiarize the students with the basics of the practical work of a natural scientist who uses the relevant methodology, has mastered the techniques of observation and of analysis and presentation of its results, and who is a productive member of the scientific community.

NS-5 was conceived as an integrated course, which is why the traditional narrow, subject-related approach is unproductive here. The integrating basis of the course is constituted by the natural scientific approach to the study of the phenomena of the outside world. Observations (including instrumental ones) of natural phenomena, their description, comparison of the obtained results and their discussion and summarization, as well as setting the tasks for the next series of observations constitute the methodological carcass of the repeated procedure performed by schoolchildren using a variety of materials. Analytical skills, practical skills in the use of different instruments and appliances (including the computer), and the habit of group work implying the members' positive interdependence are some of the expected results of this educational effort.

Over 85 % of the time is allocated to the students' independent laboratory and computer work. Each student builds his own idea and knowledge of the examined subject through personal work experience. «Collective» knowledge is generated and formalized as a result of «personal collectivization experience» stemming from communication (joint activity) with the other participants of this process.

The course is structured as a sequence of «research projects», with each following naturally out of the previous one. The materials' electronic format makes it possible to compare notes on the results through a computer network and incorporation of these results into databases. The computer network is used as a «storage facility», a source of training materials, and as an environment for organizing the collaboration of students and teachers. There is no textbook for the NS-5 course in the traditional sense. Whenever necessary, the students search for information in the «network encyclopaedia» which contains a superfluous volume of relevant information.

Training videos are used as a source of information and a means of supporting the students' independent thinking and the teachers' exchange of experience (video filming during classes).

The main forms of the work are as follows: laboratory sessions; individual/collective observations and studies; drafting reports on the results of the observations and analysis performled at school and at home; work with information sources (above all, the network database); preparing and conducting student conferences. The computer is used very extensively for processing materials, preparing reports and for writing and dispatching electronic correspondence; for interacting with the partners in training telecommunications projects; for work with the network version of training materials (selection, reading, printout); for publishing purposes (materials of student conferences, wall newspapers, final collections of the students' works).

The predominant orientation toward practical work, the students intensive group work and the electronic format of the used information (both offered to the students and independently prepared by them) combined with access to information through the global computer network and collaboration with peers in other schools and cities determine a radical revision of the «teaching architecture». The students get the bulk of facts as texts for reading (computer training database), training videos shown during classes, or the teacher's suggestions and recommendations in the course of independent laboratory work.

The teacher's level of qualifications is the crucial factor of the secondary school system in conditions of superfluity of information resources. Experience shows that the key to an efficient use of the open teaching architecture is the substance, methods and organization of teacher training. One cannot expect a teacher to create and maintain conditions conducive to student research if he himself does not enjoy such work conditions. An open teaching architecture should also be used in the training of teachers and in the methodological support of their subsequent practical work. NS-5 makes provisions for retraining and operative support of teachers. The computer network is used as an instrument supporting the teacher in his/her workplace. The teachers' methodological support includes:

- detailed familiarization with the NS-5 course before it commences;
- operative methodological support of the teachers in their workplaces with the help of the computer network;
- regular (twice yearly) seminars during the first two or three years of work;
- changes and amendments in the course.

We see that NS-5 includes means of operative methodological support of the teachers, which enables them to make an efficient practical use of the new skills and methods of work learnt during the specially organized training that precedes the introduction of the new course at schools.

Built into the methodological system of NS-5 are student joint telecommunication projects and network monitoring of the teachers' performance, which is executed by the specialists who provided the primary training. Computer communication makes it possible to set up an «invisible club» of like-minded teachers, who solve similar tasks and keep in touch without leaving their workplaces.

Retraining and subsequent teaching of the NS-5 course implies that the teacher has a PC and an opportunity of distance access to the school computer network and Internet. Retraining uses such a form as collaboration groups; there comes into being a community of like-minded professionals, a favorable 'environment for an exchange of experience and methodological discoveries and for solution of practical problems that arise as the course is taught. This community is the foundation of a future association of teachers who use the NS-5 course in their work. Setting up courses with an open teaching architecture helps form a professional community of teachers who deal with professional issues openly and responsibly. Such an association could become an effective intermediary between teachers and the public education administrative bodies, and help secondary school make the transition to work in the conditions of information society.

Today as never before it is clear that the time has come for serious international projects for developing methodological support for and standard modules of global education in the emerging global information society.

TO TEACH AND TO LEARN AT A DISTANCE: EVOLUTION OF SERVICES AND RENEWAL OF TECHNOLOGIES

Martin Vidal (France)

There are important changes in distance education, connected with rapid evolution of technological means, available to both the learners and teachers. CNED strives to provide the pedagogical services, which should meet the demands of different society strata with due regard for educational level (from primary education through uninterrupted professional background and to University), geographical distribution and for cultural context.

Those services are developing according to tempo of technological transformations and technique equipment of social and cultural spheres. At present time CNED advocates the combination of technological and pedagogical means, depending:

- *on the services offered: information, tutorial guidance, estimation, control;*
- *on definite society strata: localization; cultural, social, economical aspects; educational standard;*
- *on a number of people, involved in the same mode of background (from several dozens to several thousands, depending on the mode).*

Although the «Electronic Campus» Project of CNED corresponds, even partially, to harmonization of pedagogical services in the framework of Programme Turnpikes of information», now there is no the universal technical mechanism, identifying the features of different languages and technologies (technical mechanisms - the vectors of multimedia language, based on the appropriate symbolic representations), with possibility for interchangeable use, various rules of permutations. In this sense the two large spheres of pedagogical services in CNED are mentioned below, complemented with appropriate, will elaborated or under experimental test, technical habits: communication area, independent work area.

1. COMMUNICATION MEANS FOR TEACHERS

Presently there are several technologies, which are supposed to be used for pedagogical tasks:

On-line regime: interactive tele-transmissions and modes of communication, some modes of video-graphic communication (in a broad sense of a word), ensuring the collective work, create at distance the effect of presence. On this technique the communication between a teacher and a learner (or participants) become, more or less, individualized, more or less, personified. As the demands were determined the number of learners, their localization (the groups in special places, separate persons, combination of the direct and remote education, etc.) the technical equipment and its function may be varied.

For example:

- For large groups of learners: interactive tele-transmissions (VTI), that is the TV on general themes, during which the learners put questions directly from the place of TV course reception, that enhances a definite sense to the discussions, which are of interest to TV viewers. In this case the dialogue run on the type of «miracle»: in spite of the fact, that mass audience can't put questions to speakers, the evident questions, prepared beforehand, may arise all along a run of tele-transmission.
- For small groups of learners, located at different places: video-graphic communication is an actual remote course of lectures, in which a dialogue takes a significant room.
- Also a telephone..., in particular, for personal contacts.

But the use of on-line transmission, ensuring at some extent the "visual presence" of the participants, shall not result in coming back to restrictions, that are peculiar to our education. It is relatively easy to arrange a teleconference inside the educational institution when all learners and students are concentrated there. The difficulties can rise on attempt to arrange it in the framework of remote training, when the learners and participants are situated at different places with noticeable difficulties, but not only.

Off-line regime: the means of video-graphic communication (Minitel, Internet etc.) and all appropriate services, e-mail, forums, dialogue courses, meet excellently the requirements of requirements of distance training. They allow to arrange a learner's training with a speed, which suits him; to ensure the interpersonal communication, to present the "peripheral pedagogical" services: the discussions at distance between learners from the same background process or between teachers, while applying both the direct forums on experience exchange and virtual "professor" training. CNED disposes with a significant experience in this area, using the possibility of Minitel: now this means of video-graphic communication is gaining acceptance among users more widely, than Internet. Some aspects of human nature, tied with this mode of communication, are well known and are useful for the transmission of Minitel services to other types of network.

2. MEANS OF OPERATION IN LOCAL REGIME AND MIXED DEVICES

CNED produces some means of EAO (Education Assistant Ordinary) on diskette or CD-ROM, inside its system or in combination. But it cares of external production. Special CD-ROM, inside its system or in combination. But it cares of external production. Special CD-ROM for training or for mass users: can be applied for remote training, similar to direct training. But the medium of application can influence on conditions of pedagogical service utilization.

As to user, the area of knowledge generation and acquisition does not always prevail in significance for software, created by teachers. In fact the latter possess of a complete independence to fulfil other works by orders, for example, in the field of encyclopaedic topics. A context, within which the remote training is accomplished, can make less flexible organization of additional types of activity at distance and avoid a preliminary programming.

The Mixed devices combining the operation in local regime on the basis of special CD-ROM and ensuring direct and indirect communication with teacher, seems to be especially suitable for distance training. Thus, CNED tests the experimental arrangement of this type for language learning, when the learner operates in ordinary tempo, but under the control of interactive system, programmed in local regime, during which the multimedia link is added (audio recording of learner's product and remote leading of this product to teacher's receiver though ISDN network, while through Internet later).

Making experiment, generalization: ensure accessibility. CNED tests multimedia means and medium of their application for distance training. It also engaged with technological succession (from forums Minitel to Internet) and co-existence of the technical means, which can become necessary because of variety of audiences, equipment and cultural traditions.

The significant enlargement of a number of experimental arrangements is one of directions of CNED activity.

This work is closely bounded with a care to enable for learners an easy access to new means of information and communication technologies, to convert that, which is perceived sometimes as restriction, - the necessity of distance training - to a trump: that is to say that the training is realised at distance and should be conceived in a way to allow a learner mastering new technologies and to make his room in information society.

This care is expressed in thoughts, concerning to multimedia languages (compatible interfaces, transparency of information technologies, an attention to cultural aspect of multimedia system presentation: text, sound, image), and in search and development of access centres to pedagogical services CNED, based on utilization of technical means, where this access have also geographical, economical and cultural aspects.

MULTIKNOWLEDGE THROUGH MULTIMEDIA

Albena Kh. Vutsova,
Stoyanka R. Smricarova,
Boyko D. Denchev,
Angel S. Smricarov (Bulgaria)

Fast changes of the market labour structure in Bulgaria that as a rule is difficult to predict make necessary the preparation of the experts, which on the one hand have high qualification, and on the other - ability for fast reorientation to some of the next areas. Experience of western countries shows, that it can be reached through interdisciplinary training in so-called virtual universities with participation of the highly skilled teachers from maximum educational institution with various structure - technical, economic and other. And in practice it is possible only with using the new, more effective methods and means for training, that now offers multimedia. Multimedia can and should be a subject of interdiscipline education, as, being the group of computer - integrated Media - text, diagrams, pictures, video, audio and other, it requires the group of knowledge - on computer engineering and technology, economy, pedagogic, psychology, art and etc. These sights are incorporated and in accepted Ministry of Education, Science and Technologies in beginning of 1996 Programme for introduction interactive multimedia at the system of education. The programme provides, that all this occurred stage by stage, and on THE FIRST STAGE multimedia will be basically OBJECT of STUDY, and on SECOND - MEANS FOR TRAINING.

The realization of this program began from study and critical analysis of another experience (see table 1). It was made the connection with German Union on Multimedia, uniting the majority from organizations engaged in this area was established. Through this Union contacts with the firms, that were busy with the preparation of the experts on multimedia and development multimedia products were carried out. The following large firms in Berlin were visited: Media Design GmbH; SAE Tehnologie Institute GmbH; Comhard GmbH; Pixelpark Multimedia Agentur GmbH; LuRaTech and Multimedia GmbH, from which first three are busy educational, and other industrial activity. Four kinds of the experts on multimedia are prepared: on informatics, managers, scenarists and producers; the duration of training depends on preliminary preparation of the candidates and proceeds from 3 till 12 months at average monthly rate about 1500 DM. There are developed multimedia products for education, for presentation, for entertainment and other, and their theme and quantity are determined from the market needs. There was ascertained, that in these firms as platform is used basically PENTIUM PC and only in rare cases - POWER MAC.

Except for the companies some high schools were visited in Berlin. They are as follows: Technische Fachhochschule; Fachhochschiile fur Technik und Wirtschaft; Technische Universitat; Freie Universitat; Humbold Universitat. The multi-media technology, in itself, is commonly studied at the first university of the above mentioned, and at the three others it is used only as a teaching mean. Such hardware, as PC and work-stations, meets these objectives.

The familiarization with the analogous methods and means was carried out in England at University of Plimouth and in Belgium at Interactive Multimedia Company in Brussels.

It resulted in the following conclusion. In those cases, when multi-media technology is considered as an object, PCs are used as a hardware, and on the contrary, when multi-media technology is considered as a subject, work-stations are used. The corresponding information can be found both in [3] and in great majority of special magazines on multi-media which are edited in Germany, UK and other countries of the West.

At the first stage of the above programme the work was continued according to the plan in the following directions:

- development of the plan and curricula on interactive multi-media technologies specialization,
- development of the curricula on interactive multi-media technologies for post-graduate training,
- discussion on the above the curricula and its approval,
- development of the course of lectures for the above curricula,
- development of the project on establishment of the training interactive multi-media laboratory,
- discussion of the above project and its approval,
- establishment of the laboratories (one lab for one university),
- development of the cycle of training exercises,
- the start of interactive multi-media training,
- analysis of the results and curricula improvement.

Now the interactive multi-media curriculum is being discussed which contains the issues as follows:

- scenario development,
- text objects development and editing,
- raster graphic objects development and editing,
- vector graphic objects development and editing,
- video-information recording and editing,
- audio-information recording and editing,
- production of multi-media product circulation,
- multi-media product recording and distribution,
- multi-media and PC-network technologies integration.

The project on multi-media training laboratory is also being discussed. Such a laboratory comprises development work places supplied by PCs, and, in doing so, each place is aimed at the development and editing of the only one multi-media mean. All PCs shall be both integrated in a local networks supplied by file-server and connected with global Internet. Such design of connections will significantly improve file exchange with other nets. According to the preliminary assessment, the cost of hardware and software for such a laboratory will not exceed $ 50,000. This sum can be almost halved in the case when the possibility for simplification of the network design is used. During the first work period Internet connection is not obligatory factor, the possibility for future connection with Internet shall be considered. The other way to reduce the cost is use the printers that are cheaper than laser one.

According to Ministry plan training curricula shall be aproved and two pilot laboratories shall be established in the technical universities of Sophia and Ruse up to the end this year, and in 1997 the training of the specialists and lecturers shall begin. The specialists shall master the methods for multi-media product development and the lecturers shall master the skills of implementation of the above products for teaching process. So, objective prepositions shall be gradually created for multi-media use as a teaching mean and later for virtual universities establishment.

HIGHER EDUCATION AND INFORMATION TECHNOLOGIES IN COURSE AND DIPLOMA DESIGNING

B.S. Zechikhin, A.S. Evteev,
A.A. Zhurin, M.A. Kachalin (Russia)

The course and diploma designing is an important part in engineering education in high technical institutions.

The designing comprises concentrated expression of theoretical knowledge and practical skills, which students master during the education process. The significant sections of special disciplines are essentially devoted to various aspects of technical objects designing. Almost on each discipline design works are carried out during all training on almost all disciplines.

In great majority of the curricula on technical specialities during each semester the students carry out one or two course projects or course works, spending a lot of study hours on it. Thus each project not only serve for mastering of the studied material, but also for preparation to a following, more difficult, project. So, on younger grades of some technical specialities the designing is devoted to separate the elements of those systems, which are, as a whole, projected on senior grades. A final stage of the training process of an engineer comprises the development of graduate diploma project.

Designing of technical objects, as a rule, includes mechanical, thermal, air- and hydrodynamic, electromagnetic and the number of other calculations and it is terminated with technology development and construction design. Thus, the modern designing is so difficult and laborious that it is hardly possible to realise it without using of the means and the methods of automation.

Now the fulfilment of educational designing should be based not only upon deep knowledge of natural, general technical and special sciences, but also upon implementation of the information technologies. It is assumed the knowledge of the programming languages, skills of work with modem hardware, skill of applied software use.

The higher electromechanical education comprises studying of modern methods of automated designing of power systems and electromechanical converters (EC) included in their structure.

In Moscow State Aircraft Engineering Institute (Technical University) the works are conducted in the field of technologies for optimum designing EC of independent power systems. Thus, that the most promising direction of automated designing is a systematic detaied research of project variants before the development of design and production forms and records consideration for difficult non-linear and dynamic operation modes.

The authors have developed the technology for automation of EC optimal designing, including the development of a programme complex of preliminary automated designing and applications of NASTRAN and EMAS powerful software packages for profound studying of the project. This technology was developed with the purpose of implementation in the course and diploma designing.

The technology of EC designing automation includes the following stages:

- development of the technical assignment for project on designing;
- adoption of the constructive layout, computational model and optimization criteria;
- determination of the sizes and winding data, unequivocally describing geometry of the converter;
- development of the files for optimization parameters and varying parameters according to a priory chosen criterion and restrictions accepted in model;
- algorthmization of the optimized model;
- development of the programme for optimization calculation;
- preparation of the basic drawings of EC longitudinal and cross sections in AutoCad system;
- determination of initial data for the programme of automated designing;
- development of a software package for the AutoCad system aimed at construction of an active zone;
- development of the programme of automated designing;
- development of a programme complex for automated designing;
- choice of a calculation method, accuracy, mechanical and thermal loads for finite-element analysis of mechanical strength and heating;
- development of a typical file of the initial data for NASTRAN programme;
- choice of a type of calculation method, of accuracy level and setting up the problems of electromagnetic calculation for electrical and magnetic circuits;
- development of a typical file of the initial data for EMAS programme;
- development of the methods for course and the diploma projects execution.

Such the languages of a higher and low level, as Fortran, Pascal, C++, C etc., can be used in the process of development of the optimization programmes for calculation and designing. With the of object-oriented methods, the implementation of the C++ language gives possibility for determination of the basic physical parities and for creation of the universal classes, making easy transition to new constructive circuits and development of new models EC.

During the process of automated designing the interactive methods are applied for designing in the AutoCad system which is actually an industrial standard nowadays.

Optimization computation and designing are a base for detailed automated computation, which includes mechanical, thermal and electromagnetic calculations. The mechanical strength and heating are analysed by the method of finite elements on the base of modern NASTRAN software package. The electromagnetic analysis will be carried out on the basis of EMAS package. These packages give possibility to carry out the finite element analysis of designs with practically unlimited complexity, but also to carry out both linear, and non-linear electromagnetic computation of electrical power systems and their elements. These packages comprise extensive database on constructive and electromagnetic materials, including constant magnets. The NASTRAN and EMAS programmes are developed by the McNeal - Schwendler Corp. Company. They are used in an educational process on the base of educational-scientific centre established by the Digital Equipment Corp. Company and Moscow State Aircraft Engineering Institute.

On the basis of the above technology the authors have developed - the programme complexes for designing automation of the air trunk synchronous generator and asynchronous engine of increased frequency, and also manifold engine and independent synchronous generator with PC constant magnets. Thus the main generator is designed as a unit, consisting of three EC: pilot exciter, activator and of the synchronous generator as such. Optimization computations of the above converters are carried out on the basis of industrially tested methods with the use of modern optimization methods. The result model of each EC includes electromagnetic computation but also thermal and mechanical computations, which are of primary importance as functional restrictions. The designing is conducted according to individual criteria with rather small (up to ten) quantity of optimisation parameters and varying.

In the process of designing, the most advanced constructions of modern EC are accepted as the basic ones with the use of promising electromagnetic and constructional materials, including composite materials and high-energy constant magnets. In these constructive circuits effective cooling systems are used to increase permissible mechanical and thermal loads and to improve mass and energetic parameters of the converters.

On the base of stated technology a number of the manuals is developed for automated EC designing.

The developed technology of designing automation has required the change of methods for students' knowledge control.

Now the authors carry out the development of algorithms of multy-criteria designing optimization (according to the criteria of material and energy saving and generalized criteria of an economic efficiency).

Implementation of the developed technologies, which includes the development not only in modern applied software, but also general methods of computer science, permits to reduce time expenditures, to increase a level of EC designing and thus to improve the quality of the engineers training on a number of electromechanical specialities.

Theme 4

SOCIAL, ECONOMIC and CULTURAL ISSUES

INTEGRATIVE MODEL OF INFORMATION ACTIVITY AND VIRTUAL REALITY

M. B. Amzarakov, S. V. Shvets (Russia)

Since the end of 70-th different simulating-modelling complexes became to actively employ the computer aids of visualization. The technology of virtual reality (VR) arised on this base; it presents a simplified system for visualization of real-time processes and is realized on personal computers. At the present stage of technology development the VR aids can not only visualize scenaria, but also provoke physiological sensations and feelings during simulation of reality.

The VR technology finds wide application in different branches of activity: simulating-modelling complexes (direct purpose of the VR technology), communication aids, entertainments (virtual world).

For the last time the public health and psychological services become anxious in connection with rapid development and spread of VR throughout the world. They apprehend the complete going-away of the entire Humanity into the virtual world and, consequently, its degradation and downfall [1].

At the same time, if look attentively at the history of development of modem civilization, the Humanity repeatedly stood before a choice: live in the real world or in the world of illusions (remember ideas in the world of maya). Time suggested only various ways for going away to the world of pleasures and enjoinments: drugs, hypnotic and suggestive effects, creation of mythes (including mythical ideas of life in the ideal society). The scientific and technical progress considerably expanded the capabilities of going away from realities of everyday life by means of technical facilities, among which phone, radio, television are spreaded most of all. It seems to be not great exaggeration to say, that the Humanity tries to use practically everything, what surrounds it (it is not important whether it is created by itself or by nature) not only for direct purpose, but as an aid for going away to the «parallel world» of fantasy. That is why, it is no wonder that such new advanced communication aid, as a computer, did not avoid the same fate.

Together with development of the scientific thought the visualization technologies are improved and evidently transition from a helmet and dress to bioimpulse simulators will be the next step of VR development. The usual time the Humanity will stand before choice.

It seems, that people have really made their choice long ago: they live in several dimensions, including both world of realities and world of fantasy. And the problem consists in depth, in relation of these worlds in Man itself.

Problems of relation and measure should be considered from the point of view of the system approach, models of development and organization of the Humanity.

An integrative model [2] was earlier proposed on the basis of using cybernetic principles of constructing models of self-organizing systems, which offers to consider the Humanity as a system in its dualism, in interaction of opposite qualities in Man. The Humanity as an information system is represented by a combination of set of diagrams of interaction (DI) of opposite principles in the Humanity. Its bipolarity is traced in all spheres of existence: spiritual (good-evil), social (altruist-egoist), psycho-physiological (Yan'-In'), physiological (right-hander - left-hander). Combination of DI in all qualities and fields of Humanity display present a qualitative characteristic of the system.

Processes of interaction in the self-developing and self-organizing system «Humanity» conform to the normal distribution law (NDL). The NDL graph, plotted for any DI, gives us the quantitative idea about processes taking place in the Humanity. Boundaries of graph are determined by a number of people with clearly expressed either quality from opposite qualities, but it amounts to only some percents from the total number. The most part of the Humanity has polar qualities coexistent in a certain relation.

This model can be also applied to considering the problem about adequate perception of the VR technology by the society.

Going-away to the virtual world, created by a machine, is accompanied by several motives, based on the dominating role of one of opposite qualities, tendencies of a person: leader-outsider, strong-willed -weak-willed, optimist-pessimist, realist-idealist. Graph of distribution for every diagram of interaction of qualities, leading to motivation of using the virtual reality on the basis of model premises, has the form of normal distribution. Considering a set of constructed graphs of distribution for known DI, we may forecast the distribution for diagram of interaction of the tendency to go away into VR and its denial. The graphic representation of people distribution by «workshipper» and «antagonist» of VR will also have the form of a graph of the normal distribution law.

Consequently, for request about fanatical «workshipping» to VR we may answer, that the main mass of people, as it seems to us, will use systems of virtual reality, keeping sober mind («all time - to work, an hour - to fun»), a small part of the Humanity will really be absorbed in illusive world and a number of people will actively oppose the VR, as an aid for solving the vital problems.

Conclusions:

1. In the history of the Humanity development it more than once stood before a choice: to live in the real world or in the illusive world and in this aspect a question about the virtual reality is not a new one.
2. A research apparatus for system approach and system analysis allows us to assess the relation between world of realities and world of fantasies in Man.
3. From the point of view of the integrative model of information activity of the Humanity the development and introduction of VR technologies don't result in fatal change of external and internal activity of the Humanity.

THE CONCEPT OF ECOLOGY «MATHEMATIZATION» OR CONSTRUCTIVE ECOLOGY

M.K. Bakhteev, V.N.Dobrynin,
G.L. Mazny,
E. N. Cheremisina (Russia)

At present the term «ecology» is widely used both in science and in its practical applications. Meanwhile the interpretation of the term is ambiguous and at times inconsistent. An attribute of an extreme social actuality of ecology is a treatment of its subject in compliance with this or that scientific discipline. The negative side of this process is a subject borders breaking while the ecology is an independent scientific direction, representing methods, theory, set of methods, notations, means, problems of researches goals. In view of that, we made an attempt to define ecology as a subject of scientific activity with maximum using of modem mathematics methods and computer technologies at the analysis of problems, problems situations, putting and solving of problems, researches of the descriptions, explanation and prediction of various ecological situations.

According to the generally accepted definition the ecology is a science dealing with the relations between vegetative and animals organisms and their environment. Another definition of ecology is known as «geographic», a subject of which are dynamic processes, occurring in lithosphere, hydrosphere, atmosphere and influencing life in all aspects. Since seventieth of the twentieth century human being and social ecology is being formed. This branch of ecology studies laws of human society and environment interaction and includes various philosophical, social, economic and other aspects. At present the majority of researchers consider ecology as interdisciplinary field of knowledge covering all aspects of nature, society and human being interaction.

Protection of environment is taken as the most actual applied problem of the ecology. The ecological situation caused by society development has generated a number of political movements («Roman club», «green» parties, rescue committees etc.). These movements activity makes an accent on wide publicity, state and political authorities attention to the negative tendencies of the anthropogenic factors impact on live nature. The world community attention focuses now on effective approaches to setting up and solving the ecological problems which demands promoting new ways for operative and resulting application of both system analysis and management methods in ecology.

The researches we have conducted in a view of the described objective let us define ecology as scientific and practical sphere of activity, studying the relations between an inorganic and alive nature with the purpose of an explanation and prediction of system behaviour (i.e. inorganic + alive nature) with space and time.

A main, determining essence of the ecology, in our opinion, is relation treated as follows:

- the relation characterises interdependence of system elements;
- the relation can display as a property and attribute of things;
- a thing, taken in different relations, reveals various properties.

The relations and interdependence of things are diverse: space and time, cause and effect, part and whole relations, form and contents, external and internal relations etc. It should be emphasised, that the revealing of the relations in ecology can be of various character: on the one hand. sense of interrelations between objects is defined, on the other hand the peculiarities of the relations properties are investigated.

According to above-stated the general features of the ecosystem structure can be exposed as follows.

1. The environmental world within the framework of which the relations between live and lifeless substance are investigated. The accent on the environmental world is based on that it can be in certain relations both with separate objects (live or lifeless) and with the whole as such.
2. All the living [human beings (society, manufacturer, functioning etc.), group, community, trophic circuit etc.] Living (as well as any other subsystem), certainly, includes in itself internal connections and relations.
3. Lifeless (inorganic nature).
4. The relation between live and lifeless, describing live and lifeless interaction with space and time.

The central moment in our understanding of ecology is the research of the relation between live and lifeless, i.e. the onsideration of the following aspects: what internal properties characterize the relations, ensuring stability (instability) of the ecosystem; what properties of living and lifeless predetermine properties of the relation; what properties characterize the environmental world, ensuring the opportunity of ecosystem existence through these relations.

The objects of an inorganic nature can be characterized by the space-time, physical and chemical, biological and other properties. The most different objects, such as ground, elements of ground, water, objects, containing water, climatic space and many others can be considered as inorganic ones. Depending on the purposes of research an inorganic nature model based on space-time and other laws (known or hypothesised) is formed. These representations can base on material and/or power balance, opening or isolation of system, its stability/instability, properties, ensuring stability of the system (for example, at the expense of redistribution of substance or energy) etc.

For example, vegetative world as a whole, its separate elements or sets of elements; the animal world, the relations between elements of the animal world; the micro-world; human being in various aspects; trophic circuit and between its elements etc. - are all the objects of Live nature. The formation of live nature model is based on the concept substantial, energy, psychological and physiological, social, political and other types of balance, as well as on the system opening and isolation, its stability, properties ensuring stability etc. A main object in ecology is the human being (group or society), which is in the certain relations (known and unknown) with other objects (techno-sphere, animal and vegetative world etc.).

Depending on purposes and problems of research the model concepts, including above-mentioned ecosystem components, should met certain requirements, such, for example, as space - time correlation, completeness and independence of system description space as well as its elements, possibility of the characteristics observance etc. Structured as mentioned above the variety of concepts on constituents ecology and on possible inter-dependencies allows to determine the approach to the relations study by scheme which is relevant to mathematical researches and the exposed account of the ecology research object allows, as we believe, for efficient applying of system analysis, complex computer modelling, computer statement, solving and interpretation of the results of the appropriate problems.

PSYCHOLOGICAL CONSEQUENCES OF A CHILD'S INTERACTION WITH COMPUTER

I.G. Belavina , V.A. Zakharova (Russia)

The investigation and analysis of psychological consequences of information technologies more often processed for children of overage and senior school age. Preschool and junior school age was out of intense attention. The market of information services submitted by computer and its software producers is characterized by large variety of service opportunities of information technologies being more grown for children older than 11 years, than for children from 5 to 11 years old. The representatives of education system and manufactures of information technologies first of all assuming it as a tool to solve the problems of information education are introduced mainly to those didactic branches and subjects that are characterized by presence of sequential and strict system of rules and logic of arguments and solutions. These are mathematics, physics, Russian language and other educational subjects concerning to natural sciences.

Thus, the information technologies are introduced for creation of knowledge's, skills, experiences which are typical in case of evolution of verbal intellect. The researches, oriented at junior children age (5-11 years), testify to significant potential opportunities for information technologies to affect mot only an intellectual spheres of children, but the individual and the emotion-motivation component. According to analysis of information technologies application the age of 5-11 years is a most demonstrative from the point of view of revealing and estimation of affect level that renders this tool to the whole sphere of child mental evolution. To detect a spectrum of this information technologies effects the precise representation and understanding of an sense of this new intellectual tool is necessary. Traditionally, this tool is used for intellect evolution, however, a computer and its servicing opportunities 'provide new ways for new knowledge's and experiences to be acquired and they differ form traditionally formed by decades in pedagogical practice. The information technologies are characterized with such properties that provide to bring in the teaching of new material colourfully, dynamically, flexibly, thus rendering strong influence and switching on the emotion-motivation mechanisms of educational process. The investigation of psychological consequences requires also a clear understanding of what place and role the information technologies take in educational process. The scientific researches concerning to the investigation of peculiarities of children cognitive evolution and creative capacity under influence of computer can be divided between two trends.

Within the framework of the first trend the information technologies are a complementary link to the traditional educational process. Inside this trend the informational function promoting the development of verbal intellect can be assigned to this tool. Its mastering by children is carried out by a spontaneous and natural way and without special selection of psychological features of formation - the transformation of a computer in a tool of activity.

Within the framework of the second trend the information technologies are attached to a special activity status which takes into account a psychological essence that means such a tool that strongly affects not only an intellectual activity but the personality of a child and his self-evaluation and understanding himself while interacting with a computer. The extraction of psychological features of information technologies according to both world and native research practice gives the basis for general description of influences conveyed by a computer to a child.

If at the moment of mastering a computer we conditionally allocate three levels of mental evolution of a child as high, average and low, then from stand-point of conditional evaluation of current knowledge, skill, experience, maturity of emotional realms, cognitive standard and self-evaluation of a child we can come to the following conclusions:

1. Children with high level of current development as a result of «dialogue» with a computer receive an additional stimulus extending their creative abilities, raising cognitive motivation, forming durable interest to activity and arbitrariness of actions, in which the technologies are involved.

2. Children with average or low level of current development don't receive a positive psychological influence while adjoining with it. Subject to their personal features and, first of all, to their self-evaluation one can expect a negative effect of ambivalent reaction. Children try to avoid the following contacts with a computer or the interaction, which becomes formalized, mechanistic, «key-button» type. Sometimes children exhibit their interest to information technologies but this interest has been shifting from cognitive, educational realms to leisure games on a computer. The gained knowledge and skills are limited with a restricted utilitarian part of information technologies employment.

3. Psycho-physiological aspect of consequences, accompanying a «dialogue» of children with a computer, appears rather brightly and manifests itself both in positive and negative influences. Not touching the sanitary-hygienic features of the effects we can allocate the psychological manifestations of those influences. A «dialogue» is known to be characterized with high level of intellectual and emotional stress. Children, of junior age especially, can be exited or, vice versa, tired after studies depending on their temperament peculiarities. The interaction with a computer creates the conditions for psychological tension. The faulty actions of a child can provoke the appearance of stress, thus rendering his self-evaluation, emotions and motivation. Depending on a level of current development (high, average, low) one can expect the appropriate effect of influences. The psychological complexity of «dialogue» situation for a child with high level of development is overcome without psychological consequences. Children with average and low level of motivation correspond more often to those with unsuitable level of psycho-physiological formation of morpho-functional structures having arbitrariness off their memory, attention and thinking. Being in a stage of formation, such instability of psycho-physiological structures created a strong loading on mental evolution. This instability had required from physicians and hygienists to produce the rules and norms preventing the nervous system from provoking overload.

Thus, the selected psychological features were studies to illustrate the employment of information technologies in conditions of spontaneous - natural mastering of a computer by a child as activity means. Besides the psychological consequences of these new means of activity for 5 -11 years age the psychological essence of it was investigated. There were made the following conclusions.

1. During the transition of children from pre-school age to school age the information technologies can promote more effective formation of cognitive activity, i.e. its operational and emotional components. The intensified influence and protection from negative consequences require a specially arranged «dialogue» according to studies, taking into account the psychological essence of a computer, which, we consider, is a tool for development and correction of current evolution of a child.

2. The information technologies can provide the premises for generation of new forms of creative activity unlike the traditional ones. At a stage of transition from pre-school to school age these new forms can by best to prepare a child to school time mentally. The computerized cognition is an intermediate form between them, since their structural characteristics are similar to games and education. This, for example, may be a necessity to realise mentally the external goal and experience while mastering a computer.

3. A computer mastering results in positive consequences only after the specific skills and motivations inside the operation structure had been formed.

4. The lattice-ordered mastering with a computer needs the application of special pedagogical methods to modify a computer step by step into a tool for operation. Otherwise (spontaneous-natural formation of operation) one observes most commonly the superficial forms of computerized operations being a part of «key-button» work. The psychological-pedagogical «dialogue» techniques based on information technologies influence on children, contacting with a computer, were worked up along with a choice of software permitting to set in motion all service potentials of information technologies. To test the congruence between the research conclusions and the practical use of information technologies in education the investigation of proposed psychological-pedagogical technique has been accomplished for banishing the negative consequences. The investigations were performed with children of preschool and junior average school age.

We had been analyzing the following generalized factors: efficiency of operation; independence; mental complexity; affective-emotional trace in memory (3-5 months after studies).

The following results were obtained:

1. All children, cognising the information technologies in the conditions of «lattice-ordered» interaction, had not shown the negative consequences.

2. In the conditions of spontaneous-natural cognizing of the information technologies the affective-emotional trace (memory) of computer programmes was saved with one child (out of 17) having initially a high level of current

development. In the conditions of purposeful formation of operational structure only 20 % of children in 5 months have recollected no one computer programme, whereas 46 % of children have recollected 1 computer programme, 33 % - 2 programmes, 13.3 % - 3 programmes and 6.6 % - 4 programme (out of 5).

3. Towards the end of a year and under duration of «dialogue» between 10 and 15 minutes once a week the operational efficiency of children increased from 48 % to 73.2 %, cognitive activity - form 35 % to 78.3 %, independence - from 17.4 % to 69.6 %, whereas mental complexity reduced from 43.5 % to 13 %. The amount of errors at operation with a computer has decreased for 80 % of children (out of 25) with positive (joyful) response to errors for majority of children. For a half number of children the initiative has increased while for the others it remained the same - high, average or low. The independence at studies has raised for 68 % of children (24 % of children worked independently all the time). The expansion of necessities, that is the exit of interests out of an educational programme, took place for 44 % of children. The majority of children did not feel tired when running a computer. Also, the majority of children demonstrated an interest to a computer (basically, steady strong interest or dimple curiosity).

The efficiency like this, connected with purposeful formation of structural operation with a computer and eliminating the Therefore, the exposure of information technologies and their consequences depend on their essence as a tool for children operation and on the method of mastering this tool by a child and on mental content of those experiences, that are applied by a teacher.

HEALTH PROTECTION SYSTEM FOR STUDENTS EMPLOYING NEW INFORMATION TECHNOLOGIES IN RUSSIA

A.M. Bolshakov, E. L. Skvortsova,
E.A. Gueltischeva, V.V. Matiukhin,
O.V. Kaisina, N. I. Smirnova, Z.I. Sazaniuk,
N.G. Lopukhina (Russia)

Traditionally Russia sustains a system of health care for various groups of population over many years.

The following interconnected parts can be distinguished in this system. The first component of this system is a study of influence of people surroundings on health condition indexes, capacity for work, psycho-physiological and physiological responses, as well as on reserve ability of human organism under variety of environment intensities, which must be evaluated.

The outcomes of scientific researches are exploited for evolving of norms and rules, state standards, specifications and other documents. Thus, the second important component of population health care is the availability of state regulations as an integral part of the legislative system.

The extremely important manifestation of the state legislation is the compulsion of its execution. This precept is fixed in a number of acts and first of all in Russian Constitution, in Law of Sanitary Epidemiological Well-being. Therefore, the following link of the system lies in a control for fulfilment of existing laws, sub-law acts, and in particular, in hygienic regulations, norms and rules.

The present system set a mission to ensure well-being of people in all orbs of vital activity, among them the children's pre-school institutions, schools, high and middle special educational institutions, enterprises and organizations, performing upbringing, education and professional training.

The current information technologies are certain to open to various groups of pupils the access to untraditional sources of information, raise the efficiency of independent operation, bring completely new capability of assuming and fixing of various professional skills, provide more sophisticated assimilation of educational material and enable to realise radically new forms and methods of learning.

However, all these obvious advantages of new information technologies (NIT) for teaching can be successfully realized, as the investigation have shown in that case, if the optimal ambient medium for obtaining knowledge and skills will bring into existence and if there will be no negative influence of a complex of factors, which can be formed as a result of NIT use.

The findings obtained in Russian leading scientific institutes of hygienic profile have shown NIT both enhance the intellectual capability of man and substantially rearrange cognitive structure itself formed historically.

The training by means of personal computers (PC) and video display terminals (VDT) causes the loading of various parts of human organism. Pupils can be exposed to effect of the following harmful factors: electromagnetic fields (fields of radio frequencies), static electricity, noise, not fully adequate meteorological conditions, light deficiency and psycho-emotional tension.

Features of a character and mode training, significant for mental and other strains with new information technologies can cause to change the functional state of central nervous system, nervous-muscles apparatus of arms. Non-rational design and layout of workplace units require the maintenance of fixed poses. Under the conditions of hypo-kinetics, the durable discomfort brings about the muscles' tension growth, the development of tiredness and pupils' capacity for work decay. The negative consequences are attributable to the fact that along with durable run a computer, particularly, if the quality display is not good, pupils can suffer from distinct tension of visual perception, and complaints appear on dissatisfaction by operation, headache, violation of dream, tiredness, irritability, pain feelings with eyes, pain in a small of pupils' back, pain in neck, hands, etc.

The tiredness of users is characterized with some peculiarities, first of all by the complaints on sight organs, including sight disorders - sight obscure, troubles, while fixing an eye from short - distance objects to long-distance objects and on the contrary. Sometimes there appears both illusory change of colour of objects, their bifurcating, and unpleasant feelings in eyes, such as turning red in the eyelids, burning, conjunctivitis, pain in choroid. Most commonly the complaints are imposed from the persons with sight defaults.

The analysis resulted in finding that the foremost reason of «display asthenia» is a peculiarity of screen image in comparison with paper recording medium. The long-term combined study of functional state of central nervous system, heart-vessels system and sight organs let us to describe the main regular trends in changes of capacity for work of various ages pupils under the influence of computerized studies. In this connection it was cleared that a character and extend of favourable or negative influence over running a computer depend on duration of operating time at a screen, content, volume and set up of whole work. And also, the younger the pupils' age, the greater number of negative reactions from involved human organisms has been registered after studies.

Among a majority of factors, effecting on functional state of human organism, the great significance has, as were observed, the starting level of pupils' capacity for work and their interest to operation with VDT.

It was pointed out, that high and average starting level of capacity for work registers lower number of complaints on sight discomfort, lower range of indexes changes, which characterize the tension of sight analyser and which are not stable. In this case it is important to underline, that positive motivation of pupils toward the studies running a computer promotes the stabilization of functional organism systems, concerned to training activity.

As can be seen from the research, the pupils, along with growth of their age, are adapted to mastering of a computer. However, the period of time of its development differs from age to age. Thus, the lesser adapting feasibility was noticed for pupils of 7-11 age, that indicates that the largest number of unfavourable

lies in a capacity for work and functional states of nervous and sight systems.

The reserve capabilities under development make them more stable to influence of computerized training for pupils of middle school age, there more so as for students of colleges, high schools, resulting in decrease of tiredness.

The data obtained served as a basis for hygienic Regulations of VDT operation duration on lessons and out of lessons training for pupils of different ages and for students of high and middle special educational institutions. For this, there were determined the conditions and modes of computer operation and developed the special physical exercises to take off tiredness from various parts of human organism.

The variety of training models, like playing problems and business games, being most efficient, are provided as additional didactic possibilities. The educational information technologies makes it available for teacher to achieve the didactic goals and to use both the separate kinds of training work and any other set, that is to project the educational medium. From this point of view it is necessary to take into account that the extent of pupils' tiredness of different ages depend mainly on features and content of computerized lessons.

The computerized lessons are connected with protracted retaining of posture. The sight work is accomplished with three operational planes alternately: keyboard, copy-back and display, which are oriented at different angles. In this connection, the tiredness of operating at VDT users significantly depends on working place design, its illumination, pupils muscle state (strength, endurance, elasticity, lithe of spinal cord and joints) and ergonomic specifications of furniture. The special studies allowed to develop the basic hygiene requirements to the design of computerized working place.

These requirements are used as a basis for furniture design for computer classrooms.

As a part of hygienic exploration the optimal conditions of illumination medium were determined for users at displays. They are met along with north and north-east orientations of rooms, if common level of illumination reaches 300-500 lux for working place and 100-250 lux at the screen.

These conditions provide the favourable and stable indexes of sight functions. Under the natural illumination the display classrooms shall be provisioned with light protection and light control, since some sacrifice of image quality appears as a result of specks produced by light opening. In this case the formation of the whole operational zone is of great importance and it should be located at possibly longest distance from light openings, that is in the canter or deep inside the room. On the basis of researches accomplished in Russia, the measures of preventive maintenance are permanently under development and improvement with the aim to provide both the absence of harmful influence on pupil organism over all stages of training process and the optimal conditions of knowledge mastering. To our opinion, the preventive maintenance, concerning to effect of unfavourable factors accompanying PC training and the provision of optimal educational medium, can be distinguished as follows: hygienic, ergonomic, technological and medical. Hygienic measures comprise the recommendations of display location and room illumination, as well as of sustain of micro-climate conditions, etc. Ergonomic measures mean a correct arrangement of working place and modes of training and relaxation. Technological measures hold the improvement of display itself and short closing its properties to that of paper information carriages. Medical measures include the requirements to sight-organs of PC users, the recommendations of rational optical correction along with this operation, as will as of special gymnastics and massages during the breaks.

The developed measures constitute the basis of a number of regulations. At a time the results of this work found the reflection in Federal Sanitary Rules and Norms «Hygienic specifications of VDT, PC and operational arrangements».

Thus, the existing pupils' health care system in Russia for employing new information technologies in education includes the following elements:

1. The accumulation, generalization and analysis of information on potential impact of mode and type of operation with PC and VDT and of influence of surroundings educational Medium on pupils of different ages.

2. The study of terms of formation of such negative factors, accompanying VDT and PC operation, as noise, static electricity, soft X-radiation, electromagnetic waves, air ionization.

3. The development, expert appraisal and approval of normative documents, methodical recommendations and other regulating documents concerning to prevention of negative effects on human organism from a number of harmful factors and establishment of optimal conditions for mastering the training material.

4. The monitoring of pupils health, state of environment, following the hygienic regulations, arranging the training process.

The interaction between those elements is not simple. Thus, shortages of regulations can depend on a number of factors, including more likely the deficiency of theoretical knowledge of some processes of NIT use; the imperfection of methodical research approaches; insufficiency of combined effects accounting. Only under combined approach and cooperation experts of various knowledge orbs one can guarantee the functional efficiency of the system and, therefore the efficiency of preventing measures for pupils health care in terms of permanently improving educational system utilising new information technologies.

*UP-TO-DATE INFORMATION TECHNOLOGIES AND EDUCATION: PHYSICAL AND AESTHETIC EVALUATION OF VIRTUAL ENVIRONMENT **

G.V. Cheremnikh,
S.N. Konyaev (Russia)

As new information technologies become increasingly widespread, which applies, in particular, to the development and accessibility of Internet, the traditional problems of education, ethic and aesthetic upbringing have lately come to be regarded literally «in a different light», featuring a new, non-traditional twist in their development. Traditional, aesthetic upbringing was based on the use and interpretation of images obtained in a reflected light. Now that computer technologies have made a considerable advance, images that themselves are a source of light are in common use. Images visualized with the aid of a computer monitor, unlike their historic precursors, i.e. stained-glass windows, are characterized by a more varied colour palette (different by orders of magnitude) and, besides, exhibit a much stronger pronounced interactivity with the observer.

The nature of the original itself has changed fundamentally: a work of art produced on the screen of a display has no copies. All the copies recorded on a magnetic disk and subsequently reproduced on a monitor are originals, regardless of the distance, in the case of Internet facilities application. Thus, the concept of objects identity acquires a new sense.

The development of means to produce computer «virtual reality» broadens the potentials of the process of education and also stipulates new problems: from purely philosophic to pedagogical and medical-and-psychological aspects of trainee security. While considering the broad spectre of using the concept of virtuality, we should dwell on two marginal areas of possible worlds. On the one hand, purely mental possible worlds represented by systems of views, memory of a cognising subject, including, in a broad sense, the spaces of the works of literature, myths, theories. This category of possible worlds is essentially subjective even though the subject may be both an individual and a social organism. Another extreme case is associated with virtual processes in contemporary particle physics, where particles cannot be observed due to the uncertainties relationship, however, just like in the case of physical vacuum, this virtuality is objective.

Both aspects of the virtuality concept prove closely related to that of observation, and observer. In mental spaces, the observer is a prerequisite of virtual world existence, because any information recorded, for example, in a book or with the aid of some other medium needs a perceiving, observing, cognising system that makes it possible to perceive it. Objective physical virtuality acquires the quality of «virtuality» as long as there exist tough restrictions on observing such a reality. In other words, virtual processes of this nature cannot be followed by an observer of a particular structure with particular levels of structural organization.

Computer virtual worlds hold a special position. On the one hand, they are relatively independent, on the other, just like anything else created by humans, their descriptions are in the designer's mind and cannot function without his, albeit indirect, influence. Computer virtual worlds erode, expand the observer's boundary, both physically and mentally, by connecting manipulators and increasing memory.

As hardware and technology advance further, there may arrive a situation where it will be rather difficult to determine in what space the observer functions: objective physical or computer virtual. Today, already appropriate outfits and headsets are available, used in a virtual reality technology which, in fact, make it possible to lock human sensor receptors in a computer, programmed reality. In this context, there again an acute question arises as to whether or not human sleep or function in reality.

As we know, one of the criteria making it possible to differentiate between sleep and being awake is coherence, recurrence over protracted time intervals of the subjects of reality, unlike sleep, which, normally, has an interrupted structure. In the case of computer virtual reality, this criterion should be generalized considerably.

We feel that a concept of coherence in the sense of being harmonious, consistent, aesthetically keen on something. The concept of coherence treated in physics as capacity of light, particle to be engaged in interference generally indicates identity, a common origin or interfering particles. Virtual worlds are also characterized by a certain degree of coherence in terms of their events and structures being consistent and harmonious. At the same time, the worlds existing in the works of literature, in areas, where figurativeness is achieved through rigid logic, are characterized by virtually absolute coherence whereas objective worlds are never that coherent, considering their evolution, transformation, development.

An observer has two methods to determine that the world in which he functions is, in fact, a virtual-computer world. The first method has to do with a possibility of locating one's own receptor not locked by computer sensor transducers and, using Godel's theorem, «exiting» to an expanded system where a computer functions as a subsystem. The second method is to try and make an analysis from the inside. To do this, an observer must analyse the coherence of reality scenarios in which he functions. Simulating observations in computer reality, as G.Patty pointed out, is no easy matter: the problem consists in making a kind of additional measurements and computations. The process of observation becomes a comparison of the limitation imposed by the system with components of system description, while the process of computation is associated with implementing a particular stage of the programme. It remains to be seen whether or not the process of observation using programme interface may be used to simulate adequately the process of observation. However, in our view, solving this problem constitutes a crucial phase of computer virtual worlds development.

In addition to philosophic and theoretical aspects of possible worlds, there are specific problems of improving methods of teaching the trainees to creating images using computer technologies. At the present stage of education development it seems premature to renounce the use of traditional methods of teaching fine arts. Yet, we do not find it expedient to ignore new technical means and computer technologies as a novel powerful tool of technical upbringing and education. Visualization of information technologies touches upon the questions of the need for selection and, consequently, aesthetic evaluation of the images perceived. However, in the conditions of the growing visualization, this is not the case for virtually every user because as far as the incoming information is concerned man is most interested in the plot to such an extent that even if he develops aesthetic attitude to virtual environment, it remains at the level of visual perceptions.

Physical appraisals of the system of reflected light and artificial electronic environment are only of significance to a narrow circle of specialists: psychologists, computer scientists, physicians, artists, etc. We have to admit that aesthetic perception of different colour media introduces elements of creativity at the level of observations, then statements and transformations; moreover, the judgements passed are the subject-matter of fundamental and applied research. As far as artistic observations in incident light are concerned, there exist historically probated procedures of nurturing visual culture of perceiving and reproducing the observed light, which occurs as a result of permanent aesthetic judgements assisting in proper evaluation of the observed natural phenomena and real life subjects. Shaping up the depth of aesthetic artistic evaluation is further encouraged by the perception of the works of fine arts, which, in turn, is a specific visual medium associated with preserving the traditions of applying regularities existing in the harmonies of reflected light.

It would be wrong to think that the development and nurturing of artistic attitude towards virtual environment cannot be applied or properly appreciated. At the same time, physical characteristics of virtual environment and, above all, the glowing screen of a PC monitor are attributes of close attention given, among other things, to aesthetic properties of colour, which, without special orientation in terms of judgement, is only exercised at a low level of aesthetic requirements. Infinite identification of images is ignored and, consequently, the indifference develops toward the inadequate characteristics of an arbitrary original. Aesthetic judgement of various properties of static and dynamic images emerging on the screen of a PC monitor makes it possible to broaden the sphere of visual mentality, emotional attitude, orientation in one's actions, which becomes crucial when the user finds himself in cyber space. Unfortunately, neither the place, nor the role of elaborating the developing procedures of nurturing aesthetic judgement of perceiving virtual environment have been established at present, which may be 'associated with graphic art activity on the screen of a PC monitor. Nor has the philosophical aspect been developed that determines the procedure of assimilating the judgements of virtual environment: this, ultimately, impedes the progress of a user-computer dialog, which, just like art, may be regarded as a potent means of portraying the world.

On a practical level, there is a series handicap in the adoption of systems of teaching computer methods of creating images, common to all interdisciplinary subjects. On the one hand, the development of contemporary science calls for teaching the fundamentals of interdisciplinary areas, for new approaches to education (e.g. introduction of associative systems of education proposed by prof. Sheaffer). On the other hand, as was demonstrated at the Moscow Synergistic Forum (January, 1996), some traditional scientists and pedagogues are rather hostile towards interdisciplinary sciences regarding them as being devoid of firm foundations, which, in their view, are an inalienable characteristic of classical subjects.

Taking the teaching fundamentals of aesthetics as an example, through computer-aided images, once again we are faced with the need for studying and promoting the basics of interdisciplinary research, establishing harmonious, coherent interdisciplinary links. At present, there are two «poles», «categories» of specialists in Russia who are capable of and would be interested in advancing and adopting computer methods of creating images and who, at the same time, complement one another. At the one pole, we find engineers, programmers, developers of computers and software, who have special knowledge in the field of computer engineering, but a vague idea of aesthetic problems (such as colour, perspective, subject and other special issues associated with arts creativity). At the other pole, there are professional painters who are either unfamiliar with computer technologies, or use PC as an expedient means. We suppose that provision of conditions for co-operation of the aforesaid «poles», securing the coherence of their interaction will be a crucial step towards laying down the foundations of a new natural-science and cultural-and-historic paradigm on the threshold of the third millennium.

*NEW INFORMATION TECHNOLOGIES IN PRESERVATION AND EFFICIENT USE OF HAND-WRITTEN CARD-CATALOGUE OF THE RUSSIAN VOCABULARY OF 11 - 17TH CENTURIES IN EDUCATION (EXPERIENCE OF WORK UNDER UNESCO PROGRAMME «MEMORY OF THE WORLD»)**

Yu.N. Filippovich (Russia)

The purpose of this message is to render influence to politics of using of new information technologies in the field of education. The base for choice of such purpose is positive experience, saved within the framework of joint activity of scientists of the Russian Academy of Sciences and of the professors of higher schools in realization of the project «New information technologies of preservations and of the efficient use of hand-written card-catalogue of the Russian vocabulary of 11 - 17 th centuries on CD-ROM» (which is the part of the UNESCO program "Memory of the World").

The main two concepts are new information technology and educational technology.

More often it is total under information technology activity of the subjects; directed on transfer and transformation the information is understood. In our particular case we shall represent information technology as activity, directed on representation and transfer of knowledge, that is saved experience of activity of the subject in subject area. Such understanding permits, first, to consider any teaching (education) as some information technology, that is the information technology and educational technology at such understanding are considered as synonyms; secondly, to represent educational technology as a sequence of procedures and operations of extraction of knowledge and experience of the subject, their normalization and representation.

Hereinafter the exposition will concern "new" information technologies widely not used in educational and "new" that is offered for the first time educational technologies.

Allocate tool and subject information technologies. To tool the concern of technologies processing of the texts, diagrams, databases, spreadsheets and other. Of their presence almost of a "standard" set of universal operations and procedures of transformation of the information, submitted in a kind of the text, graphic image, numerical number is characteristic. To subject information technologies unique sets of special and universal procedures and operations, used in specific subject fields of knowledge, submitted by particular artifacts concern. In present message some tool technologies and one lexicographical work subject are considered, which is one of the main in such field of knowledge, as historical linguistics.

The educational technology in relation to tool and subject information technologies are integrated, i.e. uniting in self set of general and private procedures and operations of extraction and transformation of tool and subject knowledge. Developed in space and time, educational technology is defined not only by set of some procedures and operations, but also by set of the subjects, realizing these procedures and by set of resources (objects of knowledge).

The subjects of the educational technology are the teacher and schoolchildren, forming educational collective. We shall consider in quality of the "generalized" subject of the educational technology "educational-scientific collective", consisting from students, post-graduate students, experts with high education, teachers of high school, scientific employees.

The card-catalogue of the ancient Russian dictionary (CCARD) represents unique hand-written assembly of the citations from manuscripts and published texts of 11 - 17th centuries (chronicles, stories and messages; business books and letters, private letters and state bills). Total extracts comes nearer to 2 million. The extracts represent paper cards of the different sizes, laying within the limits of 20 - 120 mm. The extracts that are made by more than two hundreds men basically with feather handles and with inks of different colours on paper of poor quality and various density, are subject to influence of time - card-catalogue more than 70 years. The cards are stored in library boxes on the average on 1700 - 2000 pieces in each. The work with card-catalogue requires observance of rules of personal hygiene and sanitary norms.

The card-catalogue is base, on the basis of which multivolume Dictionary of Russian language (DRL) 11-17 th centuries is let out since 1975. (It was let out 21 volumes in 1995, with the words on the letters P - R). This dictionary is the result of researching work of large collective of the scientists - philologists, in creation of each volume there take part 15-20 persons. The period of preparation of one volume makes on the average 3 years. Each volume contains about 2.5 - 3 thousand words, the size of a volume - 35 author lists.

The card-catalogue and Dictionary are a powerful source of knowledge in the field of Russian historical lecsicology and lecsicographics, history and culture of Russia. The knowledge are submitted basically in two forms: in the kind of artifacts (it first of all CFARD and DRL) and in kind of lecsicographics technology as the set of receptions and procedures of work with cards and sources, organizational structure (Historical-lexicological and lexicographical Department of Institute of Russian Language named after V.V. Vinogradov of the Russian Academy of Sciences) and methodical measures.

CCARD as artifacts has three-level structure - FILE - THE CARD - THE BOX. The CCARD file has alphabetic organization. Each box CCARD has unique number, is characterized initial and final parting words and contains cards of two types: cards of parting words and card with citations. The card contains the citation рукописную an extract from certain source, underlined word in text of an extract, brief designation of a source, from which extract, and date of a source is made.

DRL has more difficult structure, however in it is also possible to allocate three levels: the DICTIONARY -ENTRY - CITATION. As well as the card-catalogue, Dictionary has an alphabetic structure. The entry is submitted by a named word and general items of information, relating to it (reference words, grammatical comments and other). Each entry is characterized by a set of attributes: by interpretation, degree of reliance, shade, presence of a connected word collocation, Greek or other language connection, source and other.

Main components of the lexicographic technology are the following procedures: formation dictionary and entries of the next volume DRL, work with sources, preparation of the text of the dictionary, edition of the dictionary. The most valuable is the experience of realization first four procedures.

Considerable meaning there is the organization of dictionary work, which has found reflection in structure of a department, distribution of the responsibility, duties and sequence of realization of separate operations.

Modern measures of lecsicographics technology contains the instructions and manuals on realization not only traditional of lecsicographics work, but also reflects experience of the using of tool information technologies, such, as technology of textual processing, technology of scanning and processing of the images, technology of databases, OCR-technology.

The integration subject (lexicographics) and tool information technologies permits to define new whole thing. Those is electronic copy of a ancient Russian card-catalogue in the form of databases and information systems, ensuring effective access to it. In itself electronic CCARD copy, placed on machine carrier of the information, represents object, access to which after its duplicating can be supplied for large number of the possible users. Thus will be saved CCARD as a historical and cultural monument. The integration subject and tool technologies in this case represents technology of preservation of historical and cultural object - the ancient Russian card-catalogue. Two various ways of duplicating electronic copy of a card-catalogue can be offered: first, duplicating by record on compact discs (CDR or CD-ROM); secondly, by maintenance of telecommunication access (creation WWW-server).

Procedures of technology of preservation CCARD are procedures of technical and philological preparation of card material to translation on machine carriers of the information; scanning and processing of the images of cards; creation of card databases; inputting of the texts of entries; creation of dictionary databases; integration of databases; creation of information systems; duplicating of components of databases (thematic samples, results of researches etc.).

Main peculiarities of integrated technology are, first, peculiarities of objects CCARD and DRL themselves (significant volume, weak normalized, semantic complexity, essential labour input of routine procedures and operations and some other); secondly, peculiarity of subject technology (the lexicographic technology of creation on basis CCARD of the dictionary is insufficient is documentary and submitted basically by experience lexicographers, which can only be observed and studied); thirdly, peculiarity of organizational and financial support (financing basically of material inputs on buying of the equipment, not enough means for payment of live labour, not regular financing and other).

The main purpose of activity of education-scientific collective is the realization of the project «New information technologies of preservation and efficient use of hand-written card-catalogue of the dictionary of Russian language 11-17 centuries on CD-ROM», maintained by UNESCO. For realization of the project it was required to bring in to integrated information technology a number of changes and additions, which are basically reduced to making the main procedures and operations of technology of character of the trainees. It changes technology and makes her educational.

On the basis of the work on preservation CCARD can be delivered and applied and fundamental scientific researches are realized, which can become a subject bachelor and master diploma projects, candidate and doctor's dissertations in the field of 'linguistics and computer science.

For 1,5 years within the framework of the project there were carried out five diploma projects on computer science, 18 individual home tasks, 32-hour cycle of laboratory work "Multimedia systems", scientific and research work, there were carried out three iniciated scientific and research work in the field of linguistics, scientific development of the postgraduate students of the philologists were conducted. Significant work on preservation CCARD is at the same time made: tool and subject information technologies are developed, databases electronic copies of a card file now make more than 10 Gb of the entered information; the first domestic compact disc with card assembly is created; a series of compact discs with thematic samples of card and dictionary materials is prepared to issue.

HYGIENIC ASPECTS OF STUDENTS' WORK AT VIDEODISPLAYS

E.A. Gueltishcheva (Russia)

Implementation of computers into the process of teaching has called for the solution of certain problems of hygiene that equally apply to students at institutions of higher education and to schoolchildren.

Since 1981 our institute is one of the first in Russia that has been engaged in the integrated research of the work of students and schoolchildren (grades IX, X, XI) at video-display terminals (VDT) and personal computers (PC).

In the course of the research, we co-operated with a number of educational establishments and scientific research institutes (Moscow Engineer-Physical Institute - *«MIFI»,* Research Institute of School Equipment and Technical Means of Education, Research Institute of Lighting Engineering, Central Research Institute of Experimental Designing of Academic Buildings, and others).

Subject to study were the following hygienic aspects:

- working conditions at VDT and PC of various types, including colour video monitors;
- organizing of work stations;
- VDT and PC working schedules for students and schoolchildren during classes as well as for students on a mission in students' field teams (during summer holidays) and for schoolchildren - during practical training;
- functional condition and health of students and schoolchildren.

Emphasis was placed on preventive measures aimed at health protection and avoiding overwork.

Work at VDT and PC in classrooms produces an unfavourable environment. This applies, above all, to microclimate: air temperature increases up to 27°C, sometimes higher; relative humidity drops to 12-18 %, the air being nearly still. This results in dry mucous membranes of the upper respiratory tracts and is detrimental to the cardio-respiratory system and kidney function. The air indoors gets polluted with harmful chemicals both due to antropogenic pollution as well as due to the destruction of polymer materials used for decorative finish of the interior of classrooms (phenol, formaldehyde, ammonia, vinyl chloride, etc.). Air-ion conditions change, too. Energizing a VDT alone in the absence of people resulted in a greater amount of negative ions, largely at the expense of heavy air-ions. As it did, the number of air-ions increased in proportion with the length of time during which VDT was in operation, and already in 1.5-2 hours their number grew 4.75-fold, exceeding admissible ionization levels. VDT and PC are sources of electromagnetic radiation. Our studies indicate that secondary X-ray radiation was below rated values. There was no infrared or ultraviolet radiation in areas «B» (320-280 nm) and «C» (280-200 nm). Electrostatic tension near the video monitor screen sometimes went beyond the rated values (150 V/cm or 15 kV/m). At times, electrostatic pressure registered near the side surface of EC 1841 video monitor was equal to 750 V.

There still exist old Russian-made VDT and PC (*«Elektronika 15И3-00-13», «EC 7066», «EC 7927», «Iskra 1030», «Iskra 1030.11», «EC 1841», «ДВК-2», «ДВК-3»*). When these are connected to the mains and begin to function, they produce noise whose level reached 63-65 dBA, in excess of the allowed 50 dBA. The specter was dominated by audio pressure levels in the area of medium and high frequencies. Operating these types of VDT and PC impaired the functional condition, in particular, of the central nervous system.

Students and schoolchildren of health groups I and II were under observation. Trainees suffering from myopic ocular refraction were sampled for studies.

Psycho-physiological tests were carried out in the course of classes, during a working day and throughout the entire period of work in students' team as well as in the dynamics of a single day and course practice.

Students and schoolchildren programmed problems using a VDT and PC. Work intensity was high, reaching 97 % of the working time. As they worked at VDT and PC, the students and schoolchildren complained they suffered from headache, sometimes from dizziness, early fatigue, and general tiredness.

Crucial to reducing fatigue of trainees' visual analyser is good illumination of the desk (an optimum illumination of desk surface has been determined - 500 lux), design features of VDT and PC: resolution, contrast, colour index of information against the backdrop of the screen.

Special studies of 10 light combinations of information colour index and screen background colour index, chosen with the participation of trainees, indicate that the 1st rank place corresponds to white information characters against a dark-green background, the 2nd rank place is filled by green characters against a black background, and the 3rd rank place occupy white characters against a black background and white characters against a blue background. An optimum distance of 60-70 cm from the eyes to the screen is established.

Concentrated mental work at a VDT or PC, complexity of problems, limited time determined by the schedule of classes result in stress situations and have an adverse effect on the functional condition of user systems. This is manifest in slower speed of data processing, loss of concentration, falling efficiency, longer time for reflex mobile responses to light and sound stimuli, etc.

The greatest visual analyzer fatigue and general tiredness was noted in persons with myopic refraction compared with individuals having a normal eyesight: they would get tired sooner, and changes of the functional state were more pronounced.

It is established that over the same length of time, computer games produce the greatest adverse changes in the visual analyzer and central nervous system, compared with operating a VDT or a PC.

VDT or PC operation for a long time, especially with an improper work station organization in fatigue and pain of the backbone, shoulder girdle, hands and legs.

In connection with the aforesaid, workstation parameters for VDT and PC operation were determined on the basis of which firm *«Elektronmash»*, Kiev, designed a desk. Its peculiarity consists in a smooth change of the surface height for the video monitor and the keyboard. Desk surface for the keyboard may change the angle of inclination, which helps to maintain a correct working posture, without a sharp include of the head forward, while the depth of this surface the distance between the eyes and the video monitor screen.

Complexes of exercises for the eyes are prepared and their efficiency is demonstrated as well as the efficiency of breaks for stretching.

As a result of studies accomplished the following parameters are substantiated:

(1) minimum area (6 m^2) and cubic capacity (24 m^3) per computer, i.e. per work station with a VDT or PC;

(2) optimum and admissible temperature and relative humidity parameters for classrooms with installed VDT and PC;

(3) VDT and PC working schedules during classes and in leisure time (students' field teams and practical training);

(4) minimum and optimum duration of intervals between paired classes.

Requirements are elaborated to organizing a workstation and to computer science studies, lecture rooms with VDT and PC. It was demonstrated that screen filters (glass-film ones, type C-14A and C-14B of South Korean manufacture, «Leer» screen filter, manufactured at Voronezh) reduced visual analyser fatigue.

An anti-X-ray varnish produced by the Research-and-production Enterprise «Spektr», Rostov-on-Don, was approved.

On the basis of the aforesaid, preventive measures are elaborated aimed at normalizing the training environment and VDT and PC working schedules, preserving the health and efficiency of students and schoolchildren.

Materials of long-term studies served the basis for elaborating 10 normative-and-methodological documents in the form of sanitary specifications and norms, methodological instructions, recommendations and normatives.

ARCHIVES GO INTERNET

Siegfrid Hermann (Austria)

5000 generations have enjoyed discovering patterns in nature. They teached each other to interpret what they saw. During the past 500 years printing was perfected. During the last 150 years photography offered universal access to the creation of high-quality images. And now in our generation photography became a mass culture tool. Computers began as number electronic machine, electronic networks promise universal dissemination of images. Think of yourself as a multimedia machine. In a new way you have to explain and understand things. Call it what it will: television, film, graphics, literature, magazines, broadcast are part of multimedia, integrated media, communication media... Education system means the collision of everything.

There is rapid development in communication media. Learning and research structures change. Together teachers and students learn in a live long process. Permanent new audio-visual medias change dramatical our routine life. New didactic effects in education arid research create new learning technologies. In education there are no borderlines. Countries are not isolated any more. Even the village in out country has permanent contact with the surrounding world. Information comes through glass fibre or satellites. Education and research become part of spontaneous interaction.

Especially young people accept this new amazing situation, A growing flood of information and research dates are potentially available anywhere in the world. Digital information technology enables the integration of text, graphics, film, animation (this are characters that move across the screen till digital holography), voice and music. MGEG enables the compression of images. New optical storage technologies use lasers to write dates on a recordable optical surface. Modelling allows three-dimensional animation. The final stage in the 3-D animation process is rendering. It blends together light sources, background images, texture and surface attributes. With morphing a seamless change of one image into an other becomes possible and warping, where only one image changes over time.

Multimedia and Internet benefits both the educational and public sector. Today's information technology is potential. We start to combine all current media more smoothly together then ever. We use technology at a price that was not dreamed of ten years ago. Teachers and researchers will become an integral part of multimedia education. One good teacher is still worth more than any amount of hardware, no matter how sophisticated the technology. Multimedia in education, and together with Internet, provide new ways for teachers and students to learn. In-class presentation and self-learning will allow to explore topics from broader perspectives. The result is interactive information and life long interdisciplinary learning.

We create a conspicuous relationship to our machines and learning programs. We become active in a very new way. Our new functions in learning are not the production of same-same-same than the creation of different-different-different. With new media a technology of diversity is invented. Therefore ARCHIVES GO INTERNET.

*IMPLEMENTATION OF NEW COMPUTER TECHNOLOGIES FOR PRESERVATION OF LIBRARY AND ARCHIVE VALUABLES**

T. A. Isachenko (Russia)

Since 1992 Russian State Library (RSL) started with realization of «World's Memory» UNESCO programme with the purpose of preservation of the library and archive valuables, which are currently under the treat of loss as a result of possible natural disasters or «cataclysms maid by people». The project objective is to imprint the most valuable from the artistic and documented points of view memorials, which are of great interest for researchers connected with the various fields of knowledge, i.e. philologists (peculiarities of writing), historians and ethnographers (connection with the regional cultures), art critics (artistic design).

The process of forecasting of future works concerning optical disks development is retarded by the facts as follows. The possibility for fixing and distribution of such information is questionable since high cost of the equipment; it is difficult to provide mass libraries and cultural centres with corresponding techniques; the readers (researchers) are not ready to work with new technologies. In spite of optimistic predictions of project authors, all the above-mentioned circumstances even now present the stumbling block for determination of principles for selection of these or that documents for saving them on CD-ROM discs and for determination of regular succession of these works.

The works which are carried out at the Department of Manuscripts under RSL and that are concerned to the composing of description of manuscripts collections, as a main point, suppose the effective utilization of computer technologies. The speed, completeness and convenience of the information sources obtaining are connected with the use of computer technique for solution of the following tasks:

1). scanning of manuscripts with consequent processing of the result patterns;

2). the introducing of the textual and graphic information on the machine carriers with consequent creation of the databases and the information systems, capable to increase the effectiveness of the work with indexes with the purpose of to acceleration of the access to manuscript patterns;

3). storage and preservation of the scientific investigation materials and the results of such investigations in the form of hyper-text database, which are being implemented, in particular, at the Institute of Russian Language under Russian Academy of Sciences.

Finally the preparation of electron publishing of the whole multi-volume «Description of Museum Collection of Manuscripts» is planned for consequent replication on compact discs.

We plan the following results of the work:

- the data of about 500 pages of graphical material will be selected and written on machine carriers (the description of 300 preservation units with accessible illustration);
- the indexes will be composed (alphabetical - for the articles and author's names and chronological) and also accordance of new and old codes will be made;
- with consideration of the recent investigations in the field of source science and codicology a bibliography will be composed;
- a database will be created and partly filled in.

The work on the composing of descriptions for manuscripts collection with the new computer technology application has no analogues in Russia. The representation of the manuscripts in the form of graphical patterns and the use of the information systems for the access to the mentioned manuscriptic memorials will allow t6 obtain maximum information about the collection of manuscripts for the scientists in the centres, equipped with CD ROM-hardware.

The realization of the project will allow the creation of the condition for partial self-funding for composing of the next volumes of the Museum Collections,

The second priority direction of the work of the manuscriptical department of RSL is the development of a set of electronic edition on the material of the memorials of Old Russian writing.

The issued texts shall possess the following priority features:

- the expression (to satisfy the interest of the readers to the published texts);
- the informativeness (to response mainly the memorial-encyclopaedic genre);
- the rarity (to possess the priority of elder lists against consequent replications).

Instead of facsimile editions of typesetting texts more active way was selected which comprises editing by means of photo-type representation method.

With the active support of the Historical Lexicology and Lexicograhy Department of Russian Language Institute n. a. V.V. Vinogradov of the Russian Academy of Sciences and at the active participation of specialists from the Moscow State Technical University n.a. N. Bauman, currently the unique memorials of the Old Russian writing and 16 th-century culture are prepared to be published on CD-ROM. These memorials are oriented to the composition of complete text database:

1. Translations of the literature of 16th century in the field of natural sciences which comprises a large texts-sources of Russian Language Dictionary of 11-17th centuries, rendered a significant influence upon the development of Russian science, culture and language. Firstly, they are as follows: «The Garden Granting Cools 1534, («Herbarium of Lubech Inhabitant», according to the list of 1616), and secondly, «On the Art of Liqueurs Preparation of Herbs» (according to the list of the end of 16th century).

2. Canonic texts of the epoch before the Ivan the Terrible reign, which are important and actual for making comparisons with the epochs of the Russian Supreme power formation. They include, first of all, «Composite Nomocanon by Metropolitan Makarii» (the 16th century manuscript).

The edition of such texts by the traditional polygraphic method is difficult due to set of reasons, in particular, due to their significant volume.

The project on the electron edition is based upon the lexicological, lexicographical and archeographical investigations of manuscripts and the scientific interpretation of type-setting texts; it is followed by coloured graphical patterns of the texts, pictures, miniatures on compact-disc, produced for consequent circulation and distribution.

PHYSIOLOGICAL COST OF COMPUTER SYSTEM APPLICATION IN TRAINING OF MEDICAL STAFF AND FACTORS INFLUENCING IT

V.R. Kuchma, N.D. Bobrishcheva-Pushkina (Russia)

The goal of the present investigation is the study of work capacity and functional organism state of persons, who are dealing with automatic teaching systems (ATS), and revealing of factors, which influence on them.

There was developed ATS, which allows to train and interrogate the user in dialog regime; evaluation of it pedagogical efficiency and physiological cost was carried out.

The expert group, which studied the theme with the help of ATS, consisted of 46 students of the 5-th form of Moscow Medical Academy (MMA). They worked with IBM PC/XT compatible computer with colored video terminals of EGA, VGA types with block letters on blue background. The studies were carried out in a computer class, where sanitary-hygienic conditions corresponded to hygienic requirements. The duration of work with ATS varied from 1.5 up to 3 hours and included not only indication and explanation of errors, but also their correction.

The studies of control group (39 persons from the same department) were carried out in similar sanitary-hygienic conditions, in lecture-room according to the algorithm, realized in AT and had a duration of 3 academic hours with two 10-minutes interruptions.

Physiologic cost was evaluated according to the investigation of mental work capacity with the help of proof tests, with consequent estimation of individual shifts; the state of visual analyzer according to the time of appearance of successive contrast (TASC);
subjective state with the help of test.

It was identified that knowledge mastering in control and experimental groups trustworthy did not differ, while the application of AT allowed to individualize the rate of studies, decrease of load on the teacher, to evaluate the student's knowledge more objectively.

In the process of estimation of physiologic cost of studies it was revealed that students, who have used AT trustworthy more often one could notice significant tiredness while investigating of mental capabilities with the help of proof tests (54,4 % against 25,7 %, $p<0,05$).

In this group there appeared a little bit more persons with decreased state of visual analyzer though there were not revealed statistically trustworthy difference. One should take into account a significant variability of individual sensitivity of visual analyzer. For example, the deterioration of its state was fixated not only in 48,8 % students, who had worked with video terminals, but also in 36,8 % students of control group, where the load on visual analyzer reduced to episodic reading of the information from the blackboard or textbook and writing it into the copy book.

We did not obtain trustworthy difference in the groups according to number of students with deteriorated patent feels, activity and feel at the end of the lessons. At the same time the analysis of average magnitudes of these parameters allowed to estimate, that the parameters of patent feels and activity trustworthy decrease at the end of the lesson in both groups, while the parameter, characterizing the spirit, trustworthy decreased only in control group. In the experimental one this parameter maintains at the former level. This result is connected with interests of students towards new form of studies and satisfying of work in such conditions. Thus, the studies with ATS have appeared more tiredness for students, though subjectively have been higher evaluated by them.

In connection with this, we have carried out search of factors, which influence on the work capacity of students with the aim of their optimization.

The introducing of ATS has allowed to individualize the rate of studies. If in the control group all the students finished it simultaneously, in experimental one 24 % of students worked up to 2 hours, 43,4 % from 2 to 2.5 hours, 33.6 % - more than 2,5 hours. According to hygienic requirements ATS proposed to students to make an interruptions in their work every 25-30 minutes to conduct gymnastics for eyes and physical-culture pauses, however only 26 % students followed these recommendations.

We have analyzed the influence of these factors on the intellectual work capacity and state of visual analyzer. It was found out, that the mental work capacity is subjected to the influence mainly of the studies duration: with it increase the number of persons with significant deterioration of visual ability increases from 27 % till 64-78 % ($p< 0.05$). On the status of visual analyzer a serious influence has the maintenance of interruption regime: among students, following hygienic recommendation there one more persons with favorable changes of TASC – 78 % against 38 %, and there are no persons with significant deterioration of it, while in the group, which worked without interruptions, the amount of such persons is 43 % ($p< 0.05$).

The SAN test analysis did not reveal the interconnections between the work duration and maintenance of the interruptions. It did not revealed the connection between the SAN parameter dynamics and that, obtained during the work with ATS estimations.

A interconnection was shown between work capacity parameters, subjective self-estimation and the presence of skill of systematic work with personal computer. The students, who have had such experience, trustworthy more rarely have revealed significant decrease of intellectual work capacity. More often the increase of spirit was mentioned at the end of the work.

The influence of strength and liability of nerve system during the second signal informational processing, extraversion and neurotizm (by H. Eysenck questioner) on the work capacity and subjective state of the organism was analyzed. Taking into account this goal the examine were divided into groups with high and low strength of nerve system (according to parameter of second signal information processing); liability of nerve system (the number of errors at decoding) higher and lower the group average; the extraversial level higher and lower than 12 a.u.; neurotizm state higher and lower than 14 a.u. After that in each group there was analyzed the distribution of individual shifts, proof tests and SAN test, while the processing included only the results of student's investigation, who worked with personal computer from 2 up to 2,5 hours.

There was not revealed any influence of these factors on the dynamics of mental work capacity according to proof tests. It was stated, that persons with poor nerve system sufficiently more often react on traditional study method by deterioration of all subjective parameters (50 % in the control group against 25 % in the experimental one). It's evident, that the work in the dictated rate, the necessity to support the attention, when the teacher interrogates other pupils, and, probably, fright of answer, typical for persons with poor nerve system, leads to quick appearance of tiredness feel and decrease of spirit. At the same time persons with week nerve system are more withstanding to monotony, which is noticed in the work with personal computer. This fact is confirmed by the presence of trustworthy negative connection ($r = -0.406$) between the parameter of nerve system strength and duration of work with PC.

One ought to mention the tendency to frequent decrease of all the parameters of SAN test in the experimental group among persons with the factor of liability higher than group average. It was revealed the connection between the duration of work with computer and liability ($r = 0.46$), that, probably, may be a reason of subjective deterioration of such student's state. It was revealed a strong trustworthy connection (the correlation coefficient + 0.86) between the knowledge mastering and extraversion expression in the experimental group. At the same time in the control group this coefficient was equal to + 0.18. Evidently, here the interest to new training forms, peculiar to extroverts, became apparent. This interest created a positive emotional background in these persons, and led to material mastering.

Since the functional status of the visual analyzer depends on the combination of screen phone and information, there has been carried out a questioning of the students through the video terminal screen about the preferable combination from their point of view. 66,7 % of students, who had a long work with video terminal, chosen the positive screen, more often the variant with black letters on blue background. The analysis of the TASC dynamics for the persons, whose choice of color screen decision has coincides with that, realized in AST or appeared to be opposed, did not reveal trustworthy changes.

The investigations, have been carried out, reveal the necessity of individual approach in case utilization of ATS on the base of PC and caring out of further investigations, concerning revealing of the factors, which might influence on the physiologic cost of contemporary informatics technologies applications in staff training.

CHILDREN'S HEALTH PROBLEM IN CONNECTION WITH THE USE OF PC IN THE EDUCATIONAL PROCESS IN KINDERGARTENS

L. A. Leonova (Russia)

Using of new information technologies in educational institutions of our country continues to increase rates. Personal computers (PC) are applied at the moment at all stages of the children education, teenagers, youth. They are used and in education process of preschool establishments - in kindergartens. Thus is planned the obvious tendency to gradual increase of number of kindergartens, using PC on employment of preschool children.

Expediency of application of this new pedagogical means is convincingly proved by the teachers and psychologists, which consider, that with the help of PC it is possible to decide the problems of general intelligent of child development more effectively (I.G. Belavina, U.M. Gorvic, E.V. Zvorigina, S.L. Novoselova, N.N. Podyakov, O.K. Tihomirov et al.).

However thus there is the very important problem of safety child - PC dialogue, as consequences of such dialogue for preschool child health are not yet investigated. The decision of a problem becomes extremely important in connection with known specifically influencing by the factors and conditions of work on PC, and also in light of known from the publications of the items of information about possible adverse influence of work with PC at organism of the adult workers and pupils of average schools. It is necessary to pay attention also at peculiarities of the growth morfophysiology development of preschool children of 5-6 years (with the children just this age employment with using PC). It is known the special liability, sensitivity of their functional systems, that, at first, promotes fast adaptation to the varying factors of the environments, but, with other, - makes defining of inability adequately to react on strong and long for this age influence. In communication with it there is a potential opportunity of occurrence of convertible deviations, and then - and irreversible diseases. All this makes the problem of study of a condition on health of the children, connecting with PC, rather urgent. The purpose of the present research was to study a condition of health of the children of 5-6 years, working with personal computers on developing employment in a kindergartens, and to compare results with a condition of health of the children the same age, not engaging on PC; research carries out in dynamics of an educational year (beginning - end).

Under supervision there was 1100 children 5-6 years: 500 preschool children, working on PC, and 600 - not working on PC. All children were from kindergartens from regions of Moscow identical social conditions of life and organization of education process. The children worked on PC *«Электроника-БК»* with color monitors as *«Электроника 32 VTC 101»* or IBM-PC on developing employment 2 times a week. Each employment takes 30 minutes, during which the children worked on PC during 10-15 minutes, i.e. the duration of dialogue with the computer was strictly regulated according to our recommendations, made earlier on the basis of experimental researches. Sanitary - hygienic condition in a computer hall of a children's garden were according to the working requirements. Used computer programs were developed by the experts (teachers, psychologists, programmers, hygiene doctors) with the account peculiarities of functional development of 5-6 years children, including the visual analyzer development, function of visual perception.

Summarizing the data of foreign and domestic researchers, concerning the study of influence of work with PC on adult organism of the PC operators, senior schoolboys and students, and taking the peculiarities of influence working with the video terminal on various physiology organism systems, we have developed the appropriate program of researching of a condition of preschool health. In medical surveys there were doctors of different participated specialities (pediatric, ophthalmologist, psycho-nevrologist, hygienist).

The results of research shows that the quota of the children on a condition of health was typical for Moscow. Essential difference between the children of experimental and control groups in the beginning of educational year was not revealed on any parameters of health. A complex estimation of health (on health groups, best was the first) there were shown, that I, II and III health group had accordingly 23, 56, 21 % of the children, engaging on PC, and 24, 54, 22 % of the children, not engaging on PC. At reinspection at the end of an educational year the tendency to reduction was revealed numbers of the children with I health group, that occurred for the account in general by growth of number of functional infringements of bearing.

It was possible to assume, that at the children, engaging on PC, the infringements of bearing to the end of an educational year will meet more often, since the work on PC is connected to a compelled sedentary pose, and it is often accompanied by muscle discomfort at adult and the schoolboys.

However the assumption made by us has not proved to be true: the functional infringements of bearing in the beginning of an educational year met in both groups of the children, number of the children with is identical frequently, and to the end of a year the broken bearing accrued too equally - on 14-16 %. Hence, the infringements of bearing of the children did not depend on their work on personal computer.

The following series of researches has confirmed this conclusion. It was shown that the number of functional infringements of bearing at preschools children during dialogue with PC is connected with infringements in argonomic and sanitary - hygienic requirements on the computer hall of a kindergarten, and also with mistakes of organization sport - sanitation work and impellent mode in kindergarten.

Thus, on the basis of the research it is possible to make a conclusion, that dynamics of a health condition of the children from a beginning to the end of educational year does not depend on their employment on PC, if they are organized with all hygienic and epgonomic requirements on a computer hall, on working place and they are carried out in strict conformity with the requirements to duration of child - computer dialogue.

Besides this conclusion concerns only developing employment, - employment, which were carried out on determined technique, that was scientific reasonable by the teachers and psychologists. It is possible, that in other conditions of the pedagogical process, at other technique work of the children, PC will render other influence on organism.

In this connection it is necessary to continue medical and physiology-hygienic control for health condition and functional condition of the children, connected with PC on employment in a kindergarten.

NEW INFORMATION TECHNOLOGIES IN THE HYSTORICAL AND LEXICOLOGICAL INVESTIGATIONS *

K. A. Maksimovich,
G. Ya. Romanova,
M. I. Chernisheva (Russia)

In the Institute of Russian language of the base of Old Russian dictionary card index (ORDC) creation of a principally new investigations on *hystorical lexicology of Russian language* recently started.

The novelty of lexicological investigation set is determined by the following parameters: the computer techniques is used for every investigation; a special program is composed for each investigation of lexicological series [by the efforts of high-educated engineers-programmers with the attraction of graduates of the Moscow State Technical University n.a. Bauman (MSTU)]; in each case a special methods are designed (from the one hand, this is individual philological methodics, which are determined by the problems of investigation, while from the other hand, - this is well defined technological methodics, which allow the realization of these problems).

The main goal of the present work is creation of series of laser discs, presenting the .whole information volume, storage in the card index ORDC, and its philological processing.

There has been formed sufficiently large collective from high-educated philologists and engineers-programmers — from the one hand, and from students-philologists (Moscow Pedagogical State University, Academy of Slavonic culture) and undergraduate-programists (MSTU) - from the other hand.

The peculiarity of the present series. is the searching character of the design, which determines partial nonpredictability of the results, since at the primary stage of the investigations only part of the problems are formulated, while the other problems are formed in the process of activities. *The searching colouring of the work* means its creative character. This feature - one of the most attractive for co-ordination of the efforts of the specialists, presenting two polar fields of science. The other feature of this investigation of series is their interconnection, defined de ORDC as united basis. In every investigational series the uniformal processing of card index is carried out by scanning (for data base «Gard index» and data base «Source index to card index»).

In the contemporary lexilogical investigations as a wide recognized factor the consideration of lexics in the frames of thematic groups is considered. In such groups the words are united not only by the theme, but also have similar semantic changes, are used in the same set expression and syntactic constructions. In their history they influence one on another. The thematic lexical groups, e. g. words, picked out on the base of their connection with actual reality, may be successfully put in the base of lexicological investigations with the use of new informational technologies.

For the investigation of lexics using new methodics there were chosen three *thematic groups* differed by content and structure: juristic terminology of Old Russia, traditional metrologic Russian lexics and a theme «Person in the Old Russian and Bizantian memorials».

The first and second themes are connected with *terminological lexics,* for which it is natural to suppose lexicographical methods of description in new computer investigations. The fact is that the dictionary by means of constitutes of ancient text and interpretation with corresponding comments is able to introduce into scientific circle a large culturological material, combining two cultures - culture, which has gone, and current culture.

Concerning the first theme «Old Russian and Church-Slavonic juristical terms» (the author-composer K. A. Maksimovich) it's supposed to create a fundamental reference guidance on the Old Russian juristical terminology, which would cover the period of creating and development of Russian state from XI up to XVII centuries. Thanks to it not only study of terms and ideas of Old Russian and Old Slavonic right became easier, but a lot of new data about functioning of Russian legal motivates in the prenational epoch are presented. There is presented new and often nowhere accounted material about complicity and functioning of Russian language book-written variety in the middle-epoch. Careful account of the data, taken from texts allows to watch the stages and peculiarities of Bizantian and West European legal terms and ideas reception in Old Russia. If necessary these is presented of comparative of Russian juristical terms and directions of Roman-Bizatian right, with corresponding terms and states and right of contiguous Slavonic peoples.

On the first laser disks it's supposed to write lexical and other informational materials, connected with the theme «Legal procedures». There would be created 5 data bases: CARD INDEX, DICTIONARY, COMMENT, SOURCE, INDEX.

The data base CARD INDEX contains ORDC scanned material from the word JUDGE up to the word JUDGABLE. The data base DICTIONARY contains lexicographical processing of given material. The base COMMENT contains systematic investigation of juristic lexic (by this a content systematization of the materials is presented in the data base DICTIONARY in the alphabetic order). The data base SOURCE contains scanned patterns of the contexts from rare and difficult of access juristic memorials. Finally, the data base INDEX includes shortened and full rate titles of the memorials, have been used during the work with this thematic group.

In prospective in the frame the thematic group «Old Russian juristic lexics» it's supposed to create a series of laser disks, material of which will be distributed between different legal spheres.

The work on theme «Dictionary of the old Russian measures» (author-composer G. Ya. Romanova) is oriented on the investigation of one the most significant layers of traditional Russian lexics - metrilogical terminology, beginning from the first memorials of Old Russian written language and up to the beginning of XX century (1918), when Russian measure system itself was substituted by metrical system of measures, born by French revolution. This lexics up to now did not have its own independent lexicographical description in Russian. The dictionary is created on the base of ORDC and its own card index, containing fragments from Old Russian memorials, abundantly using metrological lexics, as well as exceptions from the dictionaries of Russian language and artistic literature.

The study of metrological lexics present a complex problem. Metrological terminology is a subject for investigation not only by linguist, but also historian and ethnography. That is why pure philological methods and approaches to the material (etymological, textological, linguistographic) are supported by ethnographic methods. Lexicographical description of methodological lexics is carried out in a «wide cultural context», and thus it solves not only properly linguistic, but also historical-ethnographic problems. The dictionary is constructed according to the encyclopaedic-interpretation dictionary type.

In this theme the first realized in the form of laser discs, there would be measures of length, where there would be presented the following data bases: CARD INDEX, DICTIONARY, SOURCE, INDEX, ILLUSTRATIONS.

In the data base CARD INDEX there would be scanned the patterns of cards with metrological meaning, present in ORDC. The data base DICTIONARY will contain lexicographical investigations of metrological terms with linguistic-historical comment. Into the data base INDEX the would be included bibliographic information about written language memorials, utilized in the Dictionary. The data base SOURCE will contain the data about scientific sources, dictionaries, artistic works, used in the process of metrological lexics investigation. More subjective character of the lexics, included in this thematic group, in compression, for example, with semantic group «Old Russian juristic lexics», allows to create one more data base - ILLUSTRATIONS, containing figures, video fragments and audio comments, intended for illustration of textual and card index information concerning metrological terms.

The third theme «Person In Old Russian and Bizantian memories» (part I, «Appearance») (author-composer M. I. Chernishova) present a principally new scientific development in the field of Russian historical lexicology and medievistics. On the base of ethimological investigations a reconstruction of ancient Slavonic presentations about a person and his appearance is carried out. Then an analysis of card index collection is also carried out. The Old Russian presentations are revealed, the lexics of translated memorials are corresponding literature is investigated, due to which a Christian-Bizantian layer is determined. The material shows that in Middle-Ages several most important parts of the body have carried even in their appellations a special load. Thus, it's necessary to reanimate pattern associations, had appeared in the consciousness of middle-age human being.

The most important part of the work is comment, which apart from philological aspect (lexicological and semantic comments of the investigator), contains theological and philosophic considerations. In the comment it's presented a comparison of primordially Slavonic perception of the person - from the one side, and Cristian-Bizantian - from the other one. In this comment the elements of likeness and divergence between different cultural layers are also revealed.

Apart from the card index, substitional widespread additional materials is also demonstrated, for example, the most important textual fragments on Old-Slavonic, Old Russian, Greek and Latin languages. During the work on the theme 12 data bases were created: CARD INDEX, CARD INDEX+, DICTIONARY-1 ... DICTIONARY-7, SOURCES, INDEX, COMMENT.

The data base CARD INDEX contains more than 400 scanned patterns of the cards, which illustrate the use of 50 words-dividers of ORDS. The data base CARD

INDEX+ contains marks, presented by fields: extraction from the card or other source (more than 5000), text of foreign original (about 500 citations), complementary of the investigated word (objective, verbal, lexic, repeated, stable), its application (pattern/transferred, with compression), comment. In the data bases DICTIONARY-1...DICTIONARY-7 seven dictionaries are presented: historical dictionaries of Russian language, ethimologic, freeing dictionaries. The data base COMMENT contains the author's text-investigation. The data base SOURCE presents a special reading-book, containing more than 40 textual fragments, while some of them present a widen context of a citations. The data base INDEX contains brief and full rate names of more than 500 sources.

For the convince of the work data bases *screen forms* were developed, which allow to visualize either each data base independently, or their combination, reflecting the «view» of the authors of the investigation on the most interesting and deserving the attention aspects of the theme «Person-Appearance». All the screen forms are presented also in the data on the paper. The bases are connected according to the principle «one-to-many», corresponding to navigational means.

The importance and actuality of presented investigations is connected with their directions towards maintaining of the unique citation values of ORDC, referred by UNESCO to the objects of special cultural value in the frame of the program «Memory of the World».

TEACHING COMPUTER SYSTEM «CULTURE OF NUTRITION»

N.S. Potyomkina,
V. N. Krut'ko,
A.M. Bolshakov (Russia)

During all its history of humanity human nutrition draw a global influence on a lot of processes, taking place on the Earth. During several last decades the structure of nourishment has sharply changed in most of European countries, and in parallel the structure of morbidity and mortality also changed dramatically. On the base of a lot of investigations there have been determined diet connections between appearing of some diseases, death rate as a result of these diseases and nutrition structure. That is why in many countries the questions concerning nutrition normalization are put on the level of governmental policy.

In spite of the fact, that the necessity to change the current structure of nutrition become practically universally recognized and even confirmed by the presence of corresponding governmental programs in several countries, the practical introducing of the new nutrition structure is strongly empeded by a set of objective and subjective reasons.

In particular, these changes are impeded by the lack of sufficiently high educational level of the population in the field of nourishment. Its increase might significantly slope the situation by the way of nutrition structure changing, redistribution of individual and governmental means, more proper nutrition products storage and preparation, utilization of nontraditional types of food.

The important and practically non-developed question of any nutrition system efficiency subjective human ability to transfer on the proposed nutrition method, e.g. the question of diet's «psycho-physiological acceptability» for a given person, as well as algorithms of the transfer to the new nutrition regime. Finally, the success of the whole work, concerning transfer from one nutrition system to another and the duration of its use depends namely on «personal psycho-physiological characteristics».

Sufficient input into decision of mentioned problems may be put by teaching computer technology. It will allow to carry out the individual learning, to popularize knowledge in the field of healthy nutrition with the help of utilization of generalized and formalized in the form of data banks about the interaction between nutrition, health, individual peculiarities of the person and ecological conditions. It will allow also to evaluate personal psycho-physiological peculiarities, to choose, taking into account mentioned evaluation, the individual full value fond allowance on the base of optimized procedure; to control the process of diet application.

Computer systems are widely used in the scientific investigations concerning nutrition and physiology. However, we did not meet the systems, where the methods of physiological diagnostics and correction in the sanitary dietology might be used. The novelty of the proposed approach consist of the teaching of complex nutrition, health and ecological problems solution. The technology, has been designed, will allow to create new criterions for evaluation of food production quality from the point of view its influence on the increase of the duration of healthy and active life. This would lead to the global transformation of production and consumption of food products in general. The use of physiological adaptation methods to the problem of changing of habitual food ration present it self as new and significant step towards the real normalizing of people's nutrition structure.

Currently we carry out a set of investigations, the aim of which is the creating of methods and computerized technology for sanitary nutrition teaching, directed on the health increase and duration of active life; for teaching of adaptation to individual diet methods; for construction of individual rations of prophylactic, sanitary and destination; for control of the results of the diet application; for teaching, planning, evaluation and control of nutrition on the group level, including municipal, regional and state levels.

Earlier there were developed several versions of computer systems in the field of nutrition, which were intended for evaluation and planning of nutrition on group and individual level for both children and grown up. They include experimental version of real nutrition evaluation system with the help of which, in particular, the Moscow provision by fruit-vegetable production were analyzed. As another example one could present the system, developed according with the order of Ministry of nature and environment guarding for planning and evaluation of regional nutrition with determination of sources of pollution number, that are introduced into human organism with food. This system includes the block with recommendations concerning nutrition in ecological unfavorable conditions; characteristics of some types of pollution sources and their influence on the human health; characteristics of some food components from the point of view of their use as detoxicants. The proposed technology might be used in the governmental scale for organization of national and regional programs, concerning with changing of nutrition culture, as well as development of the strategy of agriculture, production and consumption of food products development.

OUTSTRIPPING EDUCATION AND FORMATION OF INFORMATION CIVILIZATION

A.D. Ursul (Russia)

Recently an intensive search of new model for the educational system (ES) took place. This new system ought to correspond to future civilization postindustrial information society.

Surviving is a goal, which humanity has put for itself and which is possible to realize only in the case of deciding of the whole complex of global problems, threatening by omnicide. The education also presents one of the global civilization problem and is in global crisis, assisting the prolongation of the unstable development model of existing. In became clear, that the way out of the educational crisis is connected with the creation of new stable (information) civilization model, which will be able to survive, while one of the main mechanism of this surviving may and ought to appear education.

Such narrow interconnection between the educational model and information civilization formation doubly seems unexpected from the philosophic point of view. The same for the fact to current civilization with its ES - is some whole and the parts. Traditional education, being the most wide social system, is at the same time one of the most conservative systems. Not for the first decade ES in its global dimension does not satisfy the needs of social life, conduction into future the values of industrial - consuming society, promotes the approach of global anthropological catastrophe.

Hence this is the essence of universal ES crisis, which, form the one side, don't satisfy the needs of contemporary society, while from the other side, already don't promote it future surviving. Being burdened by the tradition of past, contemporary conservative ES inexorably carries away the whole civilization to the gulf of approaching ecological and anthropological catastrophe. Its prevent requires the search of new mankind and ES development models.

The search of the way out from global crisis of the contemporary civilization has already led to nontrivial concepts of our common future. Even in 1987 there was published a report of the International commission on environment and development under the guidance of G.H. Brundtland, which introduced new idea of «Sustainable Development» (SD). Moreover in 1992 a UNO Conference on environment and development took place which accepted this, model for our common future.

We shall mean by the term SD a future form of interaction between the society and nature, which points out two main goals - maintaining of biosphere, surviving and arbitrary long development of the human race (immortality). In short, the transition to SD must provide the harmony or co-development (co-evolution) of the person, society and nature.

According to its essence the world education is one of the aspects of the whole industrial (unstable) civilization crisis. Thus the transition to the new educational system of XXI century must appear one of the main component of the overcoming the mentioned crisis and formation of new civilization in the framework of information- computer revolution.

Namely due to this reason the way out the crisis can't be found without the global transformations in the society itself. The main idea of the transition to new society is defined by global strategy of moving towards SD. The informatization of the society is one of the main component of this strategy, which sufficiently influence on all other components of this «great transition» towards new civilian paradigm.

The informatization of the society in its principle apart from everything else, has its main goal of creating of hybrid integral intellect of the whole civilization, capable to predict and control of joint mankind activities. This is the cause of the global *noosphere transformation* of social development, when united collective intellect of civilization might be able to direct its development and provide priority of mind, spiritual - intellectual values over pecuniary - energetic, material ones. In comparison with past and current situation, in the mature information society the consciousness in its main part will outstrip the objective reality, predict its development and consciously direct it along the noosphere trajectory of advancing moving.

In this sense the information society becomes one of noosphere stages accumulated the necessary intellectual-information potential for solving global problems of civilization, taking it out of the crisis status.

The model of SD may be realized only in the case of cardinal structural changes in the goals and structure of social activities and in the sense of concerned problem of changing of the SD role in the society. In principle it's possible to delay the date of mentioned changes approach up to future times, for example, till the global ecological catastrophe, if decelerate the whole social process and to transfer to «zero» development. However in this case one can't eliminate the catastrophe. New qualitative model of civilization development is necessary, but not elemental, rather global - controlled development, that is impossible without constructing of information society.

In the framework of this model some processes would be actually delayed, and even eliminated if possible. We mean here the social- pathological processes, distracting the mankind civilization. At the same time .other tendencies and development mechanisms, natural to socium, ought to be stimulated and even accelerated, reorienting towards the SD aims. These tendencies and mechanism include science, education and some other mainly information processes and social activity spheres, connected with informatization.

The most priority mechanism to go away from global crisis and transfer to SD model include science and education, but not in their traditional and contemporary appearance, rather SD- transformed. (The term «*SD-transformations*» means all the changes, directed towards transition to SD model, to formation informatized civilization). The science, rejecting its former features of development (which may be considered as forms of unstable development), neglecting practical all former forms of rationality, ought to transform to an activity system of noosphere-information orientation.

One of the goals of global-noosphere revolution in science is creating of SD civilization model, which will give the optimal trajectory of the transitional process into the future sphere of mind, gradually moving informational values towards the priority place.

This model ought to be realized in the framework of two main directions - scientific - technical one and scientific-educational one. These must be mainly information global - noosphere process, outstripping other social tendencies, while they create the base for SD - transformations of all life activities of people.

Scientific-educational process ought to take place in such accelerated rate and with such qualitative changes, that it may be considered a scientific-educational revolution, which would spread in the XXI century and become important consistive part of information society.

SD, absorbing scientific knowledge of noosphere-oriented science, gradually transforms from conservative system towards outstripping system, thanks to the fact, that only this information system is able to provide the surviving of the whole human race.

Only being able to predict and forecast, one would be able to realize a set of preventive, warning steps, intended to civilization surviving. ES, promoting the transition to SD model, will gradually transform to outstripping system, along with science. As a result of its «futurization»: the accents in the science will bias from past towards future. This would be a fundament of not only revival of spirituality as a result of integration in solving of global civilian problems with other cultural forms, but also of outstripping of collective human consciousness over its being. Only in this case the unstable, fraught with catastrophe objective reality yields the place to being of noosphere orientation guiding by outstripping intellect.

The noosphere-informational orientation of the new education system defines among others a lot of it important features, in the whole complex of which one can see this outstripping system. Among these features we should mention the following: creating and development of global educational system; continuity of the education through all the life of the person with prevailing of self-education, diversity, individualization and increase of diversification of education standards and specialties. Correspondingly, different models of remote education, opened and flexible education systems, automatic and expert learning systems and other education models and methods would develop with the help of informatics.

The model of outstripping ES of XXI century, based on the model of SD-civilization (the principles of which were already proposed [1]), would not translate from generation to generation unstable, pathologic life order of contemporary inhabitants of the Earth, common to all mankind archaic values, knowledge and skills, which bring nearer ecological catastrophe. The noosphere (outstripping) ES, becoming temporary permanent and over all-global, will transfer the information and activities to the present and future generations. These information and activities are oriented towards the mankind surviving, formation of global Information society, as a first stage of intellect. New scientific - education system together with other systems of spiritual sphere, promoting transfer to the SD, will become the base of information postindustrial society not only as society itself, based on knowledge, but also as «self educational society».

THE NECESSITY FOR STATE REGULATION OF THE INFORMATION PROCESS IN THE SOCIAL SPHERE

O.N. Vershinskaya (Russia)

The readiness of a society for the economic development through implementation of information and telecommunication technologies (ITT) is determined by its information background.

The models of using the information and knowledge, qualities of information processes and flows depend not only upon economic and technical factors, but also upon national I culture features.

Social and culture components of the economic analysis come more important under the conditions of distribution in connection with the fact that great majority of factors, suppress informatics development, concern mainly to this sphere.

The negative influence of the cultural and informational factor cannot be over-emphasised. The cultural background of wide layers of the population, including the computer knowledge, is very low. The people do not frequently know, what information is accessible to them, what is possible to make and how to realize these possibilities; the function «to know for to be able» is weakly developed. This problem has sharpened; and the significant part of the population is disoriented, and it has no strategy of action. At the same time, the skills in ITT field become one of the major characteristics for finding good job.

The process of informatization is doomed to failure in the case when no account is paid to existing social and cultural background of a country. For a long time the state did not give due attention to social questions, and during last years in social sphere and at first in the spheres of education the informatics was put out to the market.

All over the world the state regulation of informatization of education receives primary emphasis now. Today at the new stage of the development of an information society the role of the state in advanced countries varies from easy support to direct management.

With the purpose of overcoming of social and cultural barriers in the process of informatization development in our country, development of informatization activity of the people and formation of new information culture the state should actively join the process of informatization of social sphere and to carry out certain measures directed to calling attention of wide layers of the population to ITT. As to international experts, the influence of ITT in social sphere is acknowledged to be the most important both now and in the future.

In social sphere economic strategy for management of informatization development shall be founded upon those major measures forms of influence that are capable to help a state to solve existing social and cultural problem. They are as follows:

1. Organization of the advertising campaigns, making the experimental projects, aimed at propagation of ITT opportunities. This aspect was and remains the main one. Even though a lot of developed countries leave the development of electronic networks to the market structures, the state always actively participates in formation of demand for electronic services. Social and economic efficiency of the demonstration projects is very great, and international experience, especially experience of both France and Japan as well as our domestic experimental projects testify this fact.

2. Creation of conditions for manufacturing and distribution of consumer electronics and modern entertainment, promoting training through entertainment. Mechanisms of state support here are just the same as in the case of other industries. It is as follows: favourable taxation for private companies and state support of domestic industry.

The increase of distribution volumes of home ITT is considered as an attribute of the introduction into information society. The presence ITT at home stimulates interest to its use in educational and industrial sphere.

3. Supporting of new original decisions on computerization of provincial and agricultural schools as of the main structure that still stays viable under the conditions of an economic crisis through the development of the idea of «electronic buses», the use of old hardware of advanced domestic and foreign companies, organization of new kinds of the humanitarian support and others.

4. Support of the development of information service base in Russian language through development of domestic original software and computer games, multimedia and other products of high professional and literary quality. This support will result both in the increase of the international role of Russian language and in the development of Russian market for the modern information services in Russia, CIS countries and countries of former socialist community, where almost the whole adult population speaks Russian. It will also allow introducing the population of small cities and villages of» Russia - to civilization. Social and economic effect of even the insignificant investment in this sphere can be hardly overestimated. These investments would be a contribution into the increase of international prestige of our country, into education and culture, into the process of upbringing of young generation.

5. Direct participation of the state in following spheres: development of the informatization system for support of socially disadvantaged part of the population; development of distance learning services for disabled persons. This system can be implemented by means of the network of cable TV in medium and large cities. In the nearest future expected occurrence of the interactive cable TV shall result in a feedback that can provide an important increase of social maintenance quality through ITT.

The «out-of-budget» financing of such projects is possible in case of higher attention of local authorities; philanthropists and humanitarian help means. The offered practical recommendations permit to use the ITT opportunities for overcoming geographical, medical and economic restrictions, for creating of the conditions for improving informatization cervices in Russia, for creating of new organizational and informatization culture in Russia, and for development of new information society. As a whole, the policy of equal opportunities for ITT use for both healthy and disabled, for both young and old, for those who live in central regions and those who live far from large cities in the country, such a policy is the basis for not only informatization society but also for civil society.

The slogan founded in the industry "from living to development" as a whole can be used in the sphere of informatization. Search for the rules of such transition is a priority problem of state importance.

Theme 5

EDUCATIONAL POLICIES

SYSTEM ANALYSIS OF STRATEGIES IN EDUCATIONAL INFORMATIZATION

B. L. Agranovitch, A. L. Shamis, V. Z. Yampolsky (Russia)

The informatization of education present sophisticated long term and multiaspect process of transition from traditional to scientific capacity educational technologies. It is connected either with cultural educational traditions, root problems of educational philosophy, or pedagogical practice, requires sufficiently wide psychological-pedagogical investigations, significant volume of organizing-methodological work and creating of capital capacious infrastructure of informatization [1]. In this circumstances the efficiency of the works on educational informatization is mainly determined by methods and mechanisms of their organization.

In 1980-90 in Russia on the base of program-goal principles there was formed a planning system for long-term complex programs, concerning management activity informatization, the teaching process, project development and scientific research activities.

The development of complex programs were based on the designed by authors [2,5] methodology of system projecting. The complex program presents a document which contains combined by a goal setting complex of advisable actions, the integration of problem oriented tasks, targets, plan of resource providing and measures for its realizing. As an example one can refer to Complex program of work on creating of typical solutions of automated system of higher school management [2,4]. In the framework of this program there were foreseen the fulfilment of 715 targets on the following chapters: scientific research works on the problems of modification of higher school management (57 tasks); project works on the creation of the design of typical subsystems (30 tasks) and their development (16 tasks); the development of providing part (12 tasks) and introducing of the typical project solutions (600 tasks). The work experience of its realization has confirmed the completeness and sufficiency of formed targets, the efficiency of program-goal planning mechanisms in combination with the application of management, normative and methodological materials for users.

The resource concentration in the framework of the program allowed to reduce more than on the order of magnitude the number of designers, to -shorten significantly the terms of the development and realization, to increase the quality of the project decisions and to provide the introducing of typical solutions more than in 100 higher schools.

In 90-th years in Russia there is carried out the exchange of informatization paradigm, caused by the formation in the country of new social-economical structure, reformation of high school and principle innovation of information media. Personal computers of multisphere presentation and information processing, network local and global technologies required recomprehencion of informatization problematics, their place in higher school. This factor has found its reflection in a set of new informatization concepts. These concepts firstly contains:

- concept of higher education informatization in Russian Federation, which was developed in 1993 by advanced scientists and experts of high school according to the order of the State Committee for Higher Education of the Russian Federation *(GOSKOMVUZ);*
- concept of system integration of information technologies in higher school, designed by the State Information Systems Research Institute of Russia *(GOSNIISI)* in 1993 according to the order of *GOSKOMVUZ* of the Russian Federation;
- concept of telecommunication network in higher school education system of the Russian Federation, developed in 1994 by high school scientists according to the order of the *GOSKOMVUZ* at the support of *the Russia information systems research institute (РосНИИИС).*

All three concepts were united in the sense of necessity to create a modem information media of higher education and science as important component of the whole education system transfer to the contemporary methodological and technological base, that would result in principally new information culture.

The authors of the concepts consider, that simultaneous and frontal informatization of higher school education in Russia is impossible due to economical reasons. It is also impossible due to incompatibility of modern information technologies with traditional organizing and social-economic structures, cultural traditions and unreadiness of most of population, including the higher school workers, to act in correspondence with the requirements of information technology in the conditions of inadequate culture. The society, possessing inadequate culture, with great difficulty accepts external, in particular, technological innovations. This phenomena was well noticed by V. O. Kluchevsky in consideration with Peter's the First reforms. The failure of the reforms in this period, in his opinion, is caused by the intention of Russian to own west technology without west culture [1].

In order to form a system morphologic matrix of possible *global strategies of higher school informatization*, let's carry out the stratification of its vital activity space.

The vital activity of higher school as an organizing system, on a global level is determined by three systems: management system, spontaneous activity of higher school itself and interaction with existing media (economics, the population of the country, culture etc). There three systems, allotted according to the principle of their significance, determine the organizing strategy of higher school informatization.

The management system realizes the organizing activity concerning the process of informatization, which is characterised by centralised and decentralized management.

The significant media and management system may realize the resource provision of informatization process in different ways: uniform distribution of the resources, allotting for informatization among all the higher schools; and purpose distribution.

The high schools may realize their interaction with the existing media in the process of informatization as «closed» or «open» systems.

On the base of present model there was constructed morphological matrix of organizing strategies in higher school. The feature of this matrix consist of the fact, that it provides a full set of possible organizing strategies of modernization under accepted suppositions. The whole set consists of eight different quality organizing strategies: undirected global surviving, undirected global increase, directed global surviving, directed global increase, undirected local surviving, directed local surviving, undirected local development, directed local development. To realize that or other strategy of informatization, it's necessary to transform this strategy into a definite scenario, which in the framework of «general principles, defining this strategy, contains the description of the activity elements in the sphere of informatization.

The problem of informatization scenario forming, concern to the class of complicated weekly stratificated problems, the solution of which is impossible without qualified expertise, utilization of creative potential and personal knowledge of experts. Nevertheless, the proposed by the authors methodological means allow in a certain degree to structurise the process of acception of main decisions, defining the orientation, content and organizing forms of activities in the field of higher school informatization.

The first stage in the informatization scenario construction is the choice of strategy. According to presented model this is the choice between stagnation (surviving), quantitative (increase) and qualitative (development) changes on the informatization level; between global and local, directed and undirected informatization processes. Let's consider the most advanced strategies, oriented on qualitative shifts on the level of informatization. Thanks to the fact that selected strategies suppose purpose distribution of resources, the scenario of informatization management necessarily includes centralized function of planning and prediction. The open character of interaction with external environment in the choused strategies allow to eliminate the scenario, which suppose centralization of all management functions.

The management mechanism, typical to the developing systems, differs by the presence of two feedback contours, one of which is intended for quantitative information collection for management of functioning, while the other one is realized by the way of creating of semantic filter, which carries out the collection, storage and processing of qualitative information for management of the development [3]. The realization of such management type may be achieved by creation of Centers of informatization and redistribution of functions between *GOSKOMVUZ*, higher schools and Centers of informatization.

As a result of such redistribution there appear two feedback contours. The first one carries to *GOSKOMVUZ* level the quantitative parameters of the informatization process. The other one is intended for storage of qualitative information, its filtration, generalizing and utilization for prognostics and planning. The first of the mentioned contours is realized in standard management technologies, while the other one presents a channel of soft, reflexive management and may be realised in the activities Centers of informatization.

The next step in the informatization scenario building is definition of resource provision methods. In accordance to choused strategies the provision ought to be purpose one. So, according to expert's opinion, one of the most significant goals of high school informatization consists of infrastructure creating of informatization means and providing of its functioning. This allows to choose among possible scenario those ones, in which the purpose resource provision is oriented on informatization means and its staff support. In practical plane the choose of these scenario means the transition to purpose financing:

- of the works concerning creation of technological conditions, hardware and software, telecommunication systems, *providing satisfying of student's informational* needs, the same for teachers, managemental persons and scientists of high school;
- of arrangements concerning creation of industrial-technological base for the production of national competitive informational resources and technologies;
- scientific-educational structures and institutions, ensuring the outstripping production of information and knowledge.

While development of the scenario of interaction with the external media in the informatization process one ought to take into account, that the greatest deficit of information exists not on the level of state structures, but on the level of regional management organs, enterprises and individual users. From the other hand, the employer's-commereial structures are not ready yet to formulize and realize their informational needs, to finance expensive projects. That is why the realisation of the open type interaction with external media in selected informatization strategies ought first all to be carried ought through collaboration between higher school and regional structures.

As an other example of system analysis one may consider the corporative interests of higher school on the regional level of informatization, which obtains the increasing significance.

TEACHING INFORMATICS AND THE INTRODUCTION OF THE NEW INFORMATION TECHNOLOGIES INTO BULGARIAN SECONDARY SCHOOLS: PRESENT STATE OF AFFAIRS, PROBLEMS, PERSPECTIVES

Pavel Azalov, Daniela Doureva (Bulgaria)

Information technologies influence the social and economic development in Bulgaria as well. Regarding the phases of development in the use of IT within government, commerce and wider society, Bulgaria is in the second - information phase [1]. If IT should be coming into everyday life, an adequate training is to be ensured as early as at secondary school level.

In 1994 an international conference on «informatics in the Secondary Schools - Today and Tomorrow» *took place in Bulgaria. The present paper presents a summary of the problems discussed at this conference, highlights those approaches and results that are put into practice today and reflects our views on the future development of the teaching of informatics and IT in Bulgarian schools.*

I. WHAT DIFFICULTIES SPRANG UP WHILE INTRODUCING INFORMATICS AS A COMPULSORY SUBJECT?

Since 1986/87 academic year Informatics has been introduced as a compulsory subject for secondary education. Since then a number of problems have emerged with the introduction of the new discipline. These can be outlined as follows [2]:

• Being a new subject, Informatics had to find its proper place in the school curriculum among the subjects already established as secondary school disciplines, this led to a reduction of the workload assigned to other subjects and ultimately resulted in the emergence of some negative attitudes towards the new discipline expressed by some specialists in the Ministry of science and education. The bulk of Informatics in the school curriculum was being continually reduced as well as the age group (the class) changed. The teaching materials, designed for a particular class had to be used for different classes and workload. The balance of the position of many Informatics teachers was lost.

• The attempt to integrate Informatics in the Mathematics courses at the primary and lower-secondary level proved to be unsuccessful due to the fact that not all Mathematics teachers were adequately trained in Informatics and not all schools had tie necessary software and hardware supply.

• Neither the quantity nor the quality of the computer equipment available in the country is sufficient to start a comprehensive programme for teaching separate courses in Informatics or integrating IT within other disciplines. Although hardware and software providing of schools has been changing for the better lately, many Bulgarian schools can still be classified in the Automation phase of development in the use of IT. The number of schools whose development regarding IT can be ranked in the Information phase is considerably small, and still fewer are those schools which can be considered as making attempts to enter the Communication phase in the use of IT in the process of teaching and learning.

There are still no unified state standards and requirements for the teaching of Informatics. Undoubtedly, this constitutes yet another serious obstacle for teachers and students.

II. THE TEACHING OF INFORMATICS AND THE INTRODUCTION OF IT IN BULGARIAN SECONDARY SCHOOLS: *PRESENT STATE OF AFFAIRS AND PROBLEMS*

At the present time, a wide range of software and hardware supply is used in Bulgarian schools. Unfortunately, there still are upper-secondary schools which are only equipped with 8-bit computers in a minimal configuration of 48 KB RAM, with no floppy-disk drives. Other schools use 8-bit computers with floppy-disk drives and RAM upgraded to 64 KB. The greater majority of schools use 16-bit Bulgarian Pravetz-16 computers which are IBM PC/XT compatible. Some selected schools are provided with highly productive

IBM compatible computers with 80286, 80386 or 80486 processors or with APPLE MACKINTOSH computers. The hardware diversity in schools is inevitably linked to a diversity in software.

Most schools have only one small computer laboratory, which binders to the great extent teachers' attempts to integrate Informatics and IT into other subjects.

In 1994/5 the diversity of computer provision led to the introduction of 6 different standard Informatics curricula (modules). The availability of both equipment and specialists had to be taken into consideration as well as the students' choice of compulsory and non-compulsory subjects. These curricula, their objectives, their hardware and software provision are displayed in Table 1.

There are three ways of teaching Informatics in Bulgarian schools:

- as a compulsory subject in the Secondary Comprehensive Schools.
- as an extra or optional subject in the Secondary Comprehensive Schools and Secondary Technical Schools. Informatics is studied in the; 9th - 12th grade of the forms and in the 1st - 3rd grade of the latter. The workload assignment constitutes 72 lecture hours per year; teaching follows Curriculum No 6 or includes the information technologies described below.
- as a subject of specialization; instruction fellows Curriculum No 6 and standard final state examination is held. The examination consists of two parts: theoretical and practical.

Introducing information technologies in Bulgarian Secondary Schools

Since 1994/5 academic year a subject named *Technologies* has been in reduced in the curriculum for the 9th and 10th grades of the Secondary Comprehensive Schools through a Ministry decree N P-09-395/16. 06. 1993. The syllabus of this subject is designed by each school on the basis of the curricula offered by the Ministry of Education, Science and Technologies. One of the sub-disciplines of *"Technologies" is "Information Technologies".*

The teaching of IT varies depending on the type of school. In comprehensive schools IT is studied as a compulsory subject, 2 hours per week. The course is divided into two parts: general and special. If the 9th grade students have not attended a course on computers and operational systems before, the instruction follow a standard syllabus on *"Operating Systems with Text Interface"* ith a volume of 36 hours during the first term. This syllabus provides basic knowledge and skills necessary for the operation of IBM compatible computers and the use of other software products.

The special part varies depending on the available software the teacher can choose between some of the standard syllabi listed in the variable part of Curriculum No 6 in Table 1. The course workload of each of the syllabi is 36 hours. At the end of the course each student submits a paper, which is evaluated and graded by the teacher.

In the specialized schools the teaching depends to a great extent on the specialization. The design of the syllabus emphasises areas which meet the needs of the specialization.

With the suggested syllabi an attempt has been made to avoid the problems caused by the differences in computer provision and teachers' training. The syllabi show a differentiated approach to the teaching of informatics. However, at the same time some of them pose some contradictions and difficulties. These can be summarised as follows:

- As an extra or optional subject informatics is introduced in the 9th grade while the compulsory informatics course is in the 11th grade. Not all students choose to study Informatics in the 9th grade. The problem aims for the teacher who should be able to organize the teaching process in a way which will ensure the motivation of each student. What should be the minimum of knowledge and skills necessary to pass the course? What should be the criteria for assessment if the students have different levels of skill at the entry point of the compulsory informatics course.
- Similar problems arise when a particular school has chosen to introduce IT as an extra or optional subject in the 9th and 10th grade, The compulsory course starts as late as the 11th grade.
- In the technical schools Informatics is not a compulsory subject at all. This definitely is a deficiency of the curricula at the moment, considering the future incorporation of these graduates in the spheres of industry and services where the presence of the new IT is an indisputable fact.

III. WHAT ARE THE PROPER WAYS TO OVERCOME THE PROBLEMS LINKED TO TEACHING INFORMATICS AND IT AT UPPER-SECONDARY LEVEL?

1. The Ministry of Education, Science and Technologies should adopt uniform and consistent conception of the teaching of Informatics and the introduction of IT in education. In addition, sufficient funding should be provided for an adequate supply of at least 16-bit IBM PC/XT compatible computers for all schools. This will make it possible to match the teaching of Informatics with the increasing requirements of modern life. Taking into consideration the social and economic state of the country this problem could be solved in no less than a few years' time.

2. Standard requirements for the teaching of Informatics should be specified. Since January 1996 a commission has been appointed by the Ministry with the task to establish state standards for the teaching of Informatics.

3. The teaching of Informatics should be done in two stages:

- First stage: includes a compulsory minimum of knowledge and skills for all secondary school graduates; the teaching for this stage should be incorporated in the curriculum for the 9th grade of the Secondary Comprehensive School and the 1st grade of the Secondary Technical Schools.
- Second stage: includes additional knowledge and skills; the content of the second stage courses may vary depending on the vocational specialization of the infliction and/or hardware and software provisions. This can be incorporated in the curriculum for the 10th -12th grade of the Secondary Comprehensive School (SCS) and the 2nd - 3rd grades of the Secondary Technical Schools (STS) as an extra or optional subject. IT can also be introduced as a subject in the 10th -12th grades of the SCS and 1st - 3rd grades of the STS.

The introduction of Informatics in the 9th grade of the SCS and the 1st grade of .the STS will motivate students to choose it as an extra or optional subject in the next glasses and will provide the basis for the proper integration of IT into other subjects.

The teaching .materials, and documentation for the two stage teaching of Informatics can be arranged in modules. A successful attempt to put this idea into practice are the above mentioned curricula No 5 and No 6. The teaching materials for these curricula comprise of the course book *"Informatics II"* and the practical modules: *Word-processing - Spreadsheets; Databases; Desk Top Publishing; Computer Graphics/Computer*

Aided Design.

Such a curriculum complies closely with IFIP recommendations for Informatics curricula given in UNESCO's report entitled "Informatics for Secondary Education: A curriculum for schools".

Adopting the modular approach makes it possible to differentiate the teaching of Informatics. While the foundation level will be defined by the authorities through the educational standards, the advanced level is unlinked, matching learned interests and needs, depending only on hardware and software provision.

4. The effective implementation of IT in secondary education is directly connected with the training of Informatics teachers - for the prevent and for the future needs in this field. It is necessary to establish more regional and university centres that will train teachers of Informatics as well as other disciplines needed for the proper implementation of IT in the educational process as a whole.

The points stated above make it evident that educational institutions in Bulgaria still experiencing problems with the introduction of informatics and IT into education. Yet those problems can be solved. As the necessity of implementing IT in Bulgaria is inevitably increasing, establishing the teaching of Informatics in the secondary schools becoming a non-reversible process.

Table 1

Hardware provision	Software provision	Curriculum	Objectives	
			STUDENTS MUST KNOW ABOUT:	STUDENTS MUST BE ABLE TO:
8 bit computer 48 KB RAM, no FD	programming language - BASIC	C1	basic informatics concepts, computer architecture and functions, arrays, algorithms, programming language - BASIC	acquire basic computer skills, solving simple problems
8 bit computer 48 KB RAM, with FD	programming language - BASIC, OS DOS 3. 3 for 8 bit computer, Training File system	C2	basic informatics concepts, computer architecture and functions, arrays, algorithms, programming language - BASIC, Operating systems, Files, file management	acquire basic computer skills, solving simple problems, process Files, create simple information systems
8 bit computer 64 KB RAM, with FD	programming language - BASIC, DOS 3. 3 for 8 bit computer, Training programme environment simulating MS DOS and Text Editor	C3	basic informatics concepts, computer architecture and functions, arrays, algorithms, programming language - BASIC, Operating systems, word-processing	acquire basic computer skills, solving simple problems, work in OS for 16 bit computer conditions, acquire basic word-processing skills
	programming language - LOGO	C4	basic informatics concepts, computer architecture and functions, programming language - LOGO	acquire basic computer skills, solving various problems using LOGO
	Training programme environment simulating MS DOS and Text Editor	C5	operating systems, word-processing; The curriculum is designed for students who have attended C1, C2, C3 courses	work in OS for 16 bit computer conditions, acquire basic word-processing skills, process simple text documents
IBM XT/AT compatible computer or IBM compatible computer with 80286, 80386 or 80486	MS DOS, TURBO PASCAL 5. 5, PC TOOLS, DOSSHELL...	C6 obligatory part	basic informatics concepts: information, data structures, algorithms, program languages, operating systems, computer architecture and functions, stages and technologies of information servicing	use available tools to solve practical problems, use freely OS and servicing software potentials
	Word-processors (MicroText, Word 5.*, Works, Winword...) Spreadsheets (Microplan, Lotus 1-2-3, Works, Excel...) Database (Microfile, dBASE 3+...)	C 6 variable part	principles, potentials and typical operations of word-processing systems, Spreadsheets, elements, data type, applications; principles and organisation of relative database.	use a particular word-processor; design simple documents; design and process simple spreadsheets; solve problems using spreadsheets; design and create simple databases and extract information nut of them
	Computer graphics (CyberCad, AutoCad...) System Planimetrics		functional potential and operation at a particular 2D graphics System: basic working principles of System Planimetrics; basic Infoitnatics and Mathematics concepts and relations	create simple drawings and 2D structures with practical application; carry out mathematical experiments and formulate hypotheses, create mathematical models and investigate their features

ON THE SYSTEM OF INFORMATION AND METHODICAL ENSURING OF HIGHER EDUCATION

P.G. Buga

One of the main and determining terms for accomplishing of directed evolution of higher school is a methodical and information ensuring, comprising:

- the process of creation of information sources on the basis of a scientific research;
- the satisfaction of information demands of educational training and scientific research process. Taking into account the complexity and multi-aspect character of the solution of problems for a methodical-information provision at any level (federal, regional (segmental) and domestic) a systematic approach to the problem was developed.

The traditional and new information sources in higher education are as follows:

- training means (textbooks, methodical - training guides, audio-visual manuals, training softwares and instructions):
- scientific literature;
- data bases and knowledge bases;
- official documents;
- and so on.

Their elaboration, manufacturing, quality estimation and marketing need a significant intellectual and material expenses, and a solution of the complex of scientificmethodical and organizing-management problems.

In this connection it is important to orient the scientific researches and developing management measures on the solution of the following tasks:

- to estimate the required means of information-methodical ensuring and their list on the basis of the state standards of professional training, of approximate curricula and programmes;
- to carry out the scientific-methodical works on determination of a structure and content of each teaching tool;
- to select authors, producers and compilers (on the basis of competitions);
- to elaborate the long-term (perspective) and short-term (annual) programmes- for creation, issue and production of education means;
- to arrange programmes fulfilment;
- to solve the problems of manufacturing, making copies of training means, gathering and carrying out of the orders from universities, academies and institutes;
- to solve the complex of problems concerning the organisation of information-methodical provision of each user.

The multi-variant character of realized in universities, academies and institutes professional curricula, as well as the independence of educational establishments, had demanded the appropriate invariability of programme-methodical ensuring, publishing activities of higher schools, providing a retention of general library-bibliographical approaches in services of information users.

Thus, the Programme of 3-level system of higher school publishing was elaborated for higher schools in Russia in 1993-1995, including:

- I level - printing of textbooks for humanitarian, natural-science, common-professional and common-special disciplines (federal set) through central and the largest university publishing houses;
- II level - printing of textbooks and manuals for special disciplines of regional (segmental) component through regional and segmental publishing houses of higher school institutions;
- III level - printing of educational literature for special courses, as well as teaching-methodical literature having regard to demands of educational process through publishing departments and centers, being in hand in all higher schools of the country. The programme takes into account the structure of a State Educational Standard of higher professional education and the possibility to issue textbooks prepared accordingly to authors programmes.

The programme offered is acceptable for creation and publishing of other educational means. The Programme involves the problems of development of polygraphic base of higher school. With this in mind a competition of grants between universities, academies and institutes of the State Committee for Higher Education of the Russian Federation was held in 1995-1996. The competition results revealed up to 65 regional higher schools in Russia, which are ready to accept the functions of inter-school polygraphic centers for publishing of textbooks and scientific literature.

In an effort to convert the university libraries into the centers of information provision in educational-teaching

process and scientific research along with higher Russian schools the following special programmes were developed and are now under fulfilment:
- the formation of book funds;
- the introduction of new technologies in library services;
- the provision of accessibility of higher school libraries for students, teachers and research workers;
- the fitting out of libraries with copy-multiplier machines and modern library technologies;
- the provision of preservation and involving into teaching process and scientific research the funds of rare books;
- the normative-methodical provision of library-information work in higher school;
- the setting up the foreign literature funds for higher school libraries;
- the development of international cooperation of Russian libraries.

For the purpose of operational and effective information distribution and the provision of higher schools of all users of state standards with approximate and authors' curricula and programmes, of information on teaching and other literature, on means and new technologies, there shall be established a special information fund of normative-methodical documentation and tools and technologies for higher professional education, and the basis for it should be the Research Center of quality problems in the training of specialists. A creative team of specialists of higher education was formed to establish in 1996-1997 the above mentioned fund and attract to its formation the universities, academies and institutes, training-methodical associations and scientific-methodical counsels.

CURRENT STATE AND PROBLEMS OF TEACHING AIDS AVAILABILITY AT THE EDUCATIONAL ESTABLISHMENTS OF THE UKRAINE

A.N. Gurzhy, Yu.A. Zhuk,
V.V. Samsonov (Ukraine)

Successful adoption of new information technologies in education is impossible unless these are *effectively combined with traditional educational technologies on principles of harmonious mutual complementing one another.* This necessitates qualitative development of the traditional educational technologies and of teaching aids (TA) as their crucial component.

Assessing now the availability of TA at the educational establishments of the Ukraine, one should note the growing gap between the. current requirements to the tooling of the teaching process and economic-and-production capability of the industrial sector of national economics to meet them. The main reason for the gap is the collapse of the system of TA development, manufacture and supply to educational establishments that existed in the former USSR as well as the changes going on in the Ukrainian system of education. Content-wise, 60 % of the programmes of education and bringing up children at the kindergartens have been revised. New subjects have been introduced at general education schools (getting to know the Ukraine, valeology, fundamentals of ecology, and others), new sections in the traditional subjects (combinatorial analysis and statistics in mathematics, etc.), the number of hours allocated to study particular subjects has changed considerably. With the apperance of new types of schools increased (174 gymnasias, 154 lyceums, 74 private schools), differentiation between the schools has there are more schools now with an in-depth study of particular subjects. In vocational training 250 vocational training schools have changed their specialization, with 77 new higher schools, 5 fine-arts and 6 vocational school-cum-agricultural firms established. In consonance with the Ukrainian Law «On Languages», a further steady transition to the Ukrainian Language is under way as a language in which teaching is carried out. At present, 58.3 % of all children attending general education schools, 50 % vocational training schools, 65.2 % nurseries and kindergartens use Ukrainian as a language of teaching. Over 1/3 of the schoolchildren are taught in Russia, there are 7100 kindergartens for Russian, Moldavian, Hungarian and other children. This has resulted in a considerable variativity of the programmes, a profound restructuring of the curricula, in the state and school training components being introduced in the curricula.

Under the new syllabuses, the Ministry of Education of the Ukraine has developed standard lists of teaching and visual aids and technical means of education, on the strength of which effort is being made to raise the level of TA availability, at the educational establishments. The purpose of the said Lists is to secure the state component in education: they put together a basic TA module for each subject of the state component of an.appropriate type of educational establishment.

TA availability for various subjects at all types of educational establishments varies from 5 to 60%. The lowest availability is in the subjects of the humanities cycle (14%). This is due to the socio-political changes in the life of society and their influence on the process of training at school. TA availability for natural science and math subjects is low (22 %). For example, today, only 7-15 % of lessons in physics, biology and chemistry in senior grades can be held under the programme of laboratory and practical classes. The schools lack chemical reagents, the necessary visual aids, mock-ups, modules, etc.

Depending on the kind of TA, the level of TA availability for schools varies from 5 to 42 %. The situation is really bad with technical means of education. The level of TA availability at vocational training schools and secondary technical schools equals 30-48 %.

In pre-school upbringing, of crucial importance is a game and various appropriate toys. Plaything industry in the Ukraine numbered 400 factories in 1990, which turned out over 5000 different toys and met 25 % of the population toys requirements. After 1990 depending on the kind of toys, their assortment has fallen 3-7 times. The toy becomes increasingly primitive; the number of the teams of authors developing new toys has dropped 20 times.

Considering the pressing problems of providing schools with teaching aids, the Ukrainian Cabinet of Ministers undertakes centralized financing of several programmes developed by the Ministry of Education. Special emphasis is placed on cartographic products in geography and history. Production of 72 wall maps, 5 atlases and 2 globes has been launched. 20 wall geographic maps are being delivered to schools. A complex of aids in geography (a text-book, wall maps, an atlas, contour maps, working note-book) for the 6th grade was prepared and issued towards the 1995/1996 academic year.

An important area is the development and production of printed teaching aids. What makes it valuable is the low cost of the product, short production period and many potential uses. In 1995, more than 40 sets of posters in different subjects were prepared.

The entire Stock of educational films is being transferred to a video format, which involves an appropriate adjustment to the current programmes, translation into Ukrainian and copying.

In association with the Ukrainian Academy of Pedagogical Sciences higher educational establishments and sectoral institutes of the Ministry of Education of the Ukraine a programme is being developed for equipping the studies of physics, chemistry and biology on the principles of a modular approach and of transition to new generations of teaching equipment for a demonstration and frontal experiment, involving PC. The project will signify the first steps towards practical application of new educational technologies. A number of systems facilitating the study of physics, chemistry and other subjects are being tested on a pilot basis. These include an electronic reference version of Mendeleeff's periodic table based on a microprocessor module with a direct access to memory.

To implement the aforesaid programmes effectively, intense organizational effort is now under way associated with (a) integrating the sectoral and local budgets for centralizing the financing, development manufacture and delivery of TA, (b) searching for effective forms of attracting foreign firms as suppliers of TA to educational establishments, setting up a state-run system of protecting the sphere of education against the penetration of TA that fail to meet psycho-pedagogical, aesthetic and technical requirements. The first step in this direction is the establishment of an Intersectoral Artistic-and-Technical Board for toys and educational-game aids with a view to putting into effect the state policy in the field of developing and manufacturing toys, educational-game aids, playground environment for the children of all ages.

The programmes financed from the state budget include priority TA without which the study of particular themes is impossible. Developments submitted by authors are subject to reviewing and approval of the scientific-and-methodological commissions of the Ukrainian Ministry of Education.

Implementation of specific programmes in 1996 will make it possible to increase the availability of appropriate teaching aids by 10-17 %.

REFORM IN THE EDUCATIONAL SYSTEM OF THE RUSSIAN NORTH ON THE BASIS OF NEW INFORMATION TECHNOLOGIES

T. K. Karatsuba (Russia)

Arctic North of Russia comprises 70 % of the territory of the country situated northern in reference to the 65 parallel, its population makes up more than 12 million.

The natural potential of the Russian North is of global importance as far as here is concentrated, the huge amount of natural resources, such as oil, gas, nickel, cobalt, lead, gold, ores of rare metals etc.

The Russian North is the ecological and territorial reserve for our planet as a whole.

The extreme nature and climate conditions are typical for the Russian North. This region is far from cultural centres; the regional infrastructure is not developed, and the industry of the Russian North is characterized by enclave development. The population is not uniform and its tendencies towards migration are very strong. 30 types of the aborigine of the Russian North are interested in preservation of the traditional directions of economic activity and traditional *modus vivendi.* The communicative disunity inside the region is the main feature of the local life resulted from vast of the North.

The Arctic North of Russia is currently experiencing a crisis implying drastic decline in production which comprises the major part of Russian export. It is also characterized by serious social and demographic problems resulted from considerable decrease of construction of social tenant housing, public medial and cultural, housing, substantial increase of unemployment, decrease of standard of living of the North inhabitants, snowballing process of skilled labour outflows, escalation of both contradictions between industrialized regions and aborigines' needs and of general social tension converting in some places into clash.

In the Russian North the environment situation is hard in the industrial regions, the degradation of environmental systems continues and it threatens with pollution of the surrounding areas, including those out of Russian boundaries.

All-round strengthening of the social basis of the Russian North, prevention of degradation and race suicide of the aborigines, holding of skilled staff of entrants, all these points are conduit sine qua non for renaissance and crisis-free development of the Russian North.

New educational strategy is the major requirement and method for implementation of the above key social problem.

At present, all educational structures of the Russian North, these are comprehensive school and vocational school, are in crisis that results from lack of funding. At northern national schools 30,000 aborigines study. They live at the distance of 3 or more kilometres from school, that is why they have to study and live at boarding schools. As a result, the most important in the North the mechanisms for generations succession is broken out. It causes social infantilism of youth, loss of fathers' experience in traditional callings and trades, increase in potations and alcoholism.

The major directions for the reforming of educational system shall be as follows:

- the problems of financing shall be solved, the investments into education shall be advantageous for commercial banks, companies and private persons both native and foreign;
- development of the basis providing possibility for children to live and study in their families with the purpose of preservation of language and home medium that is quite necessary for children upbringing in the old folks traditions;
- co-ordination of activity of researchers, teachers, representatives of authorities, of all institutions interested in the education reform, in task-oriented development of training programmes and methods for upbringing and apprenticeship taking into the account national particularity on the peoples of the North and new educational technologies;
- supplementation of general comprehensive education by general vocational education;
- professional orientation towards traditional for North peoples specialities, such as fishery, reindeer breeding, hunting mastering etc.
- development of the system for continuous ecological education of children and adults;
- arrangement of the improved labour training with the purpose of making up the following specialities: cross-country vehicle driver, radio-operator and reindeer breeder, fur farmer, master for fur treatment, master for national fashion industry etc.;
- development of normative and legal basis for new educational policy for North.

In the Russian North the basis for educational system reforming is considered to be the combination of the educational methods and general and early supplying of comprehensive and vocational schools, the North villages and North aborigines families by the means for new information technologies. The educational process and methods should be improved, research centres shall be established, the system for continuous ecological education for adults and children.

Distance education development is desirable according to the "Centre - Northern territories" general scheme. With this purpose the use of conventional mass media means is necessary, especially such as radio, TV and video, and special video courses shall be developed for various groups of people.

In the same time, mass PC connection with Internet and other computer nets is very important under the conditions of North.

Ecological educational system can be highly intensified through connection to ICLIE (International Council of Local Initiatives for Environment Protection) programmes by means of Internet.

ICLIE is acting as a centre for well-balanced development, for environment policy, for development of local programmes and methods. It also co-operate with local authorities with the purpose of carrying out of mutual environmental campaigns. ICLIE also organizes distance learning courses on ecological management for the officers of local self-administration. This is also of great importance for the Russian North in view of the fact, that the educational method realizes the idea of collectivity of the students and co-ordinator on retention of the individual approach through interactive communications.

There is good possibility for participation of research and industrial institutions of the North in the «Esprit» European programme which contributes to improve technical knowledge and implement new technologies in the sphere of production and management.

With the purpose experience exchange in the field of new technologies mastering under the conditions of the North, it is desirable to establish communications and to carry out exchanges with arctic regions of Alaska, Canada and Scandinavian countries.

Of course, the implementation of the idea of overall computerization of the Russian North calls forth substantial funding. But with the account of its planetary importance, the Russian North can count on unequivocal financial and investment support of both the Government of Russian Federation and all interested institutions including the foreign ones.

Proposals

1. *To include into the text of the Second International UNESCO Congress Recommendations the clause on the necessity for reforming of the educational system for the Russian North on the basis of on-line and general implementation on the new information technologies.*
2. *To ask UNESCO to include the problem of reforming of the educational system for the Russian North into the priority chart. To develop and to launch the «Reforming of the Educational System for the Russian North on the basis of new information technologies» Programme.*

3. *To incorporate into the list of the developers of the Programme, the Russian public organization «Polar Russia» The Union for North Renaissance» which was established with the purpose of effective support of Russian policy.*
4. *To charge «Polar Russia» The Union for North Renaissance» with an important mission of presentation «The Reforming of the Educational System for the Russian North on the Basis of New Information Technologies» Programme to UNESCO by 01 October, 1996.*

SOCIAL INFORMATICS IN THE SYSTEM OF HIGHER EDUCATION IN RUSSIA

K.K. Kolin, I.V. Sokolova,
B.A. Suslakov (Russia)

I. SOCIAL INFORMATICS AS A NEW SCIENTIFIC AND TEACHING DISCIPLINE

There are passed more than seven years since the moment, when in several russian higher schools a new discipline called *social informatics,* began to study. This direction appeared on the junction between informatics, phylosophy, sociology, economy and psychology as a result of necessity of complex study of society informatization process and its possible social consequences.

One ought to comprehence informatics as a system of knowledge about production, processing, storage and distribution of all kinds of information in the society, nature and technical systems.

However in the community opinion, not only in Russia, one can meet the idea according to which the term «Informatics» in concerned only with the last media - technical one. That is why there appeared a demand to «protect» the subject field of scientific investigation, dealing with informatic society problems, by a special term.

In modern comprehencion the *social informatics* is a science, which studies a problem complex, concerned the information processing passing in the society and its informatization.

It's well known, that concept postindustrial information society was proposed by the western scientists (D.Bell, J.Geebrate, J.Martin, I.Masuda, O.Toffler). However it obtains more and more acknowledgement in Russia (N.N.Moiseev, A.I.Rakitov, A.D.Ursul [1]). Hence, one should take into account, that social informatics as a new scientific direction and educational subject, appeared in Russia and has not analogs abroad.

Currently the educational course of social informatics is used in curriculum of the student and post-graduate preparation in the- leading russian universities - in Moscow, St.-Petersburg and Nijniy Novgorod. It is studied in the Lomonosov's Moscow State University (MSU), at all the departments of Moscow State Social University (MSSU), in the Institute of Youth and also Russian Academy of State service at the President of Russian Federation.

In the four Russian higher schools there have been created and successfully function the social informatic departments, while in 1994 there was created an Association of these departments to coordinate their scientific and educational-methodological activities.

Since 1989 in Russia annually the scientific-methodological seminars are carried out. They are concerned to actual problems of social informatics. The scientists from Russian Academy of Sciences, Russian Academy of Natural Sciences, Noosphere Academy and International Academy of Informatization take in active part in these seminars. Scientists from abroad, the teachers from higher and secondary schools, specialists from federal and municipal organs of the educational system are also invited to these seminars. The materials of mentioned seminars are published in the scientific press in the form of individual collections *«Social informatics»,* which are edited annually since 1990 [2,4]. Another collection - *«Problems of Social Informatics»* is edited by MSSU regularly since 1995 [5-7].

Fundamental and applied investigations are actively carried out in Russia on the actual problems of social informatics. Recently also the candidat's and doctor's degree thesises are also prepared. Moreover, a explanatory dictionary on main terms is also developed.

That is why one can surely consider that in russian scientific and education spheres there has been storaged a define experience of social informatics problems study and its teaching, which surely deserves some analysis and generalization. However, before starting to do it, it's advisable to characterize the *subject field of the social informatics* in brief, its main problems and directions of development.

2. THE STRUCTURE OF THE SUBJECT FIELD OF SOCIAL INFORMATICS AS A NEW SCIENTIFIC DIRECTION

The social informatics, as well as every aria of scientific knowledge, has a multilevel structure:

The first level - theoretical-methodological - includes main cathegories, ideas and low-governed nature of information processes in the society;

The second level - of informatizing sociology - present a social «cut» of economical, legal, psylological and other aspects of informatization;

The third level - empirical one - includes the social aspects of creation, introducing and adaptation of information technologies in the society.

The structure of the subject aria of the social informatics as a science may be presented by four large problems [2]:

1. Information resources of the society.
2. Information potential of the society.
3. Low-governed nature of information society formation, as regular historically inentable stage of civilization progress, changes of social structure of society in the conditions of informatization.
4. New possibilities and problems of person in the information society.

As of educational aspects of social informatics problems, one ought to stress the strategical importance of *informational culture society* increase, e.g. the increase of degree of it readiness to the effective social utilization of new information means, different types of information resources and producing of new knowledge.

At the same time during last years it became more and more evident, that the level of main part of society readiness for informational media utilization significantly lags behind the rate of it development. One of the main reason for this is *the inertia of the existing education system in the information field.* That is why now we need not only informatization of the whole education sphere, rather also the including into the permanent educational system of special curriculum on the fundamental, in particular - social, base of contempory informatics. These courses ought to be obligatory.

3. THE EXPERIENCE OF SOCIAL INFORMATICS TEACHING IN THE HIGHER SCHOOLS OF RUSSIA

In the National Report of the Russian Federation to the Second International Congress UNESCO «Education and informatics» [3] the problems of social informatics are considered in the form of one of the main part of prospective course *«Fundamental basis of informatics»*, which is proposed as a basic for the higher school system. In Russia there already exists an experience of teaching of a special course on social informatics as an independent discipline either in the universities, or in the system of retraining of the specialists with higher school diploma.

It's evident that current Russian student, future specialist of 21st century, most exactly known the low-governed nature of new information epoch development, to understand, that his own theoretical preparation may also influence on the possible consequences of informatization, either positive or negative.

The goals of the MSSU curriculum *«Fundamentals of social informatics»*, which is first in the practice of russian education obligatory course in the framework of the cycle of general humanitarian preparation and is dedicated to study of theoretical-methodological problems of information society, include:

- creation the basis of skills to orient properly in a new information reality;
- formation of representation about the necessary to master the computer literacy, without which the organic including of the person into information environment of the society and active support its progress is impossible;
- methodological preparation to father study, mastering and participation in the design of information technologies in the corresponding subject area: socioligy, psychology, economics, social work, jiriprudence.

In the condition of rapid modification of the informational technologies and development of the possibilities, providing by them, the question of upbringing of goal life settings of the individual person maintain actual.

The structure of the course *«Fundamentals of social informatics»* studied in MSSU, includes the following themes:

- social informatics; the subject and goals of the course;
- the main ideas of theoretical informatics;
- social communications;
- information resources and information potential of the society;
- informatization of the society: prerequisities and consequences;
- formation of information environment of the society;
- information style of life: the society and person in the informatization conditions;
- information society: social structure, specific features of labour activities.

Currently in several russian higher schools one can notice an active formation of social informatics as a whole complex of teaching subjects [4].

By combining of the theoretical informational methods and also social and informational approaches, the social informatics obtain new pulse for its future development in the condition of transformings in Russia. One ought to take into consideration that namely informatization allows to intensity mane processes in the society, while the social informatics, as a scientific basis of informatics, provides the opportunities of scientific analysis and predicting of future development of these processes.

All these factors underline *fundamental properties of social informatics* as a new sociological scientific direction and educational subject - its adapting, integrity, logical slenderness, reasonably.

As for *applied significance of social informatics*, it may be illustrated by the results of sociometrical investigation, which has been carried out on the Department of social informatics in the Institute of youth. The results of this investigation are presented in the table.

№	The title of the subject	Correlation coefficient	Rang
1.	Social modeling	0.9	1
2.	Social statistics	0.8	2.5
3.	Social predicting	0.8	2.5
4.	Social pasportisation	0.7	4
5.	Social diagnostics	0.6	5.5
6.	Sociometrics	0.6	5.5
7	Social planning	0.5	7
8.	Social administration	0.4	8.5
9.	Social management	0.4	8.5

Twenty eight respodents - specialists in social work - were proposed to evaluate the degree of correlation of «Social infprmatics». subject with other subjects of social profile. The results of the investigation have shown that social informatics provides sufficiently wide interdiscipline connection and, hence, may be used as *base discipline in preparation of experts for social sphere.*

USE OF TELECOMMUNICATIONS IN EDUCATION AND SCIENCE IN THE REPUBLIC OF BELARUS

P.D.Kukharchik, N.I. Listopad,
Yu.I. Vorotnitsky, A.N. Kurbatsky,
S.V. Kritsky (Republic of Belarus)

Today information is one of the most important strategic resources of a society's development. It caused the inflow of tidy investments in the creation of information systems and technologies.

Computer telecommunications are the natural continuation of integration trends in the development of informational systems. The combination of computer techniques and means of communication emerge the new computer function — they become a means permitting to widen the scope of the information space of a given organization, to expand the opportunities of the information interaction up to the scope of a city, region, republic and, finally, to provide entering the world information space.

At present, a lot of global networks and informational centres are functioning on the Belarus territory. They have different organization and technique. The most significant among them are:

- ***BelPAK*** — The state network for data transmission. It has the national status. It is based on the application of the protocol X.25. This network, as the other analogical national networks for data transmission in other countries, offers a powerful technical foundation and a wide range of universal services.
- ***EUnet/Relcom*** — A commercial international network, offering the services of e-mail, teleconferences, access to Internet, Usenet, etc.
- ***GlasNet*** — A public non-commercial international network, offering, first of all, e-mail services.
- ***Sovarm Teleport*** — A powerful commercial network, offering rather expensive services of access to Internet and other networks, which are kept in with protocol X.25.
- ***CITEC*** — A commercial information system. In fact, it represents the enhanced electronic advertisement desk BBS.
- ***BASNET*** — The network of the Belarus Academy of Sciences. Besides servicing the Academy's organizations and institutes, it offers the services of e-mail and access to international networks.

At present, the mentioned networks do not offer the full size direct exit to global networks of Internet. This exit is realized ether through e-mail, which doesn't provide an opportunity to use the on-line regime in the work with information systems, or through protocol X.25, which emerges some technical problems, reduces throughput and increases the price.

One of the most developed computer networks of the Belarus Republic is the non-commercial network UNIBEL It integrates the leading educational and scientific organizations of the Republic, offers the wide range of correspondingly cheap services. The main aim of UNIBEL is to provide access to the global community of Internet networks for the organizations of social sphere on the non-commercial base.

The creation of UNIBEL network pursues the following objectives:

- the overcoming the disconnection between universities, institutes, scientific centres, laboratories, groups of researchers and separate scientists, teachers and students. To provide them with the opportunity of free informational exchange;
- the solution of the problems related to the dissemination of new ideas, scientific results and publications in the field of education;

- the following general technical policy in the field of information technologies introduction in the educational system of the Republic. It will allow to increase the efficiency of using the resource of an educational institution and of the concrete worker of education and science. It will provide the opportunity to use efficiently the national informational resources of the Republic;
- dissemination of information technologies; education and popularization of computer telecommunications in the field of education.

The development of the UNIBEL network is implemented in the following directions:

- the closer co-operation with the network of the administrative control system after the educational system of the Republic; the creation of an integral republic network on their base;
- promoting long term information programmes, first of all on the base of attaching to the network the largest libraries, archives, centres of scientific and technical information and the expert service of the Republic;
- the development of the connections and realization of mutual programmes with scientific and research organizations (branch and academical);
- gradual attaching to the network the system of secondary special education and secondary schools, non-state educational institutions;
- attaching (the direct and through BelPAK) governmental and public organizations, funds, etc.;
- the organization on the base of the central unit of the Centre for specialists training and an inter-HEI research laboratory of network technologies. Today, the number of foreign organizations and funds are promoting the creation and the development of the educational and scientific network of the Republic. The Institute of the Open Society (USA) gave Belarus a grant for the creation of an optical fibre ring around Minsk — *Minsk Internet Project.* The implementation of this project provides our educational institutions and scientific organizations with the full access to the global computer network Internet.

There was gained a grant from UNESCO for the attachment to the computer network of the educational departments of the Regional Executive Committees of the Belarus Republic. Our activity was promoted by NATO Scientific Committee of the informational filling of the creating network.

The creation of a real information infrastructure has only started in the Belarus Republic. However, people realize that information is an extremely valuable and perspective commodity, and the information market is one of the most dynamic and roomy. Nowadays, many governmental, commercial, scientific and public organizations are promoting their activity in the field of computer communications and information technologies on the whole.

TRAINING OF SPECIALISTS IN TWO FIELDS: INFORMATICS AND ECONOMICS

K.I. Kurbakov (Russia)

The efficiency of information systems is largely determined by their economic efficiency. As shows the global and domestic experience the economists and the specialists in informatics cannot independently solve this problem.

For this reason on the base of Branch of informatics in Russian Academy of Economics (RAE) at the support of the State Committee for Higher Education of the Russian Federation there was carried out the first stage (1986-1995) of two-profiles preparation of the specialists in informatics and economics.

The usually one second of specialty can be received as the second high education, as a rule in 2-3 years. Moreover in Russia specialization in given specialty is widely used. For example, on senior rates of education of an engineering specialty profound the studing of economic disciplines is carried out, and the high school lets out the engineer-economist usually for certain branch of a national economy.

In the experiment at RAE an in essence new problem is delivered: to prepare in five years of education the expert simultaneously on two base specialties.

Fulfilment of all programme permits trainee to receive two state diplomas:

1. On specialty *"Information systems in economy"* (qualification of the specialist is the informatist-economist, term of education - 5 years);
2. On specialty *"Economics"* (qualification of the specialist is bachelor on economics, term of education - 4 years).

The student during education receives three working specialties:

1. Programmer (1-4 category) - in two years of education;
2. Projector of automated information systems (1-3 category) - in 4 years;
3. Interpreter of English / German language - in 2-3 years.

The decision of the similar unique education problem has become possible on the base of program *"Sciencefull technologies of education (STE)"*, which is carried out under aegie of Direction of the scientific programs of the State Committee for Higher Education.

The main principles of education remains: an individualization, computerization, informatization, system organization of education, oriented to the probably complete account of problems of the subject area.

Peculiarities of educational process are flexible specialization, raised motivation of education, high level of independence of education under advisory management of the teacher, necessary computer and information maintenance of the student and other.

The first stage of experiment (1986 - 1995) has given rather high results: 30-35 % of the students in academic group (from 25 persons) ended the given program of education with distinction.

The second stage is now begun, which assumes increase of efficiency of preparation on main professional cycles of disciplines (computer, informatics, economics).

In the RAE there is the necessity to start the complex of the educational-methodical documents:

1. *The state educational standard of higher professional vocational education. The state requirements to minimum contents and level of preparation specialists-informatist on interbranch specialty 07.19.00 - Information systems (on areas of application). Is entered into action 05.07.1995.-M,: GOSKOMVUZ of Russia, 1995. -p. 28.*
2. *Provisional curriculum on interbranch specialty 07.19.00 - Information system (on areas of application). Qualification of the specialist: informatist. Term of education: 5 years. - M.: GOSKOMVUZ of Russia, 1995. - p. 10.*
3. *Provisional two-profile curriculum on interbranch specialty 07.19.00 - Information systems (area of application - economics). Qualification of the specialist: informatist - economist. Term of education: 5 years. - M.: GOSKOMVUZ of Russia, 1995.- p. 12.*
4. *Curriculum on interbranch specialty 07.19.00 - Information systems (area of application economics). Qualification of the specialist: informatist - economist. Term of education: 5 years.-M.: RAE, 1996.- p. 10.*
5. *Collection of the educational programmes of general professional and special disciplines on interbranch specialty "Information systems (on areas of application)» / K.I. Kurbakov. - M.: RAE., 1996. - p. 242.*

The large collective of tutors - informatists of a number Moscow higher schools has begun creation of twenty manuals on given specialty.

INFORMATICS IN RUSSIAN SECONDARY SCHOOLS: THE STRUCTURE OF TEACHING

A.A. Kuznetsov (Russia)

Analysis of the ways the foundations of informatics are taught and a new perception of the goals to be achieved by the introduction of this subject at secondary schools shaped by more adequate understanding of the general educational and, if you will, philosophical potential of this subject point to the need to identify several stages in the learning of informatics and the shaping of information culture in the process of school education.

The first stage (forms I - VI) is an introductory one. The children learn to use the computer and shape the primary elements of information culture as they use educational games, the simplest training programs, etc.

The second stage (forms VII - IX) provides a basic course to ensure a mandatory general minimum volume of knowledge of informatics. During this stage, the children learn to use the methods and means of information technologies for problem solving, form the skills of conscious and rational use of the computer in their school work and later in their professional activity. Doing the basic course enables them to shape the idea of the process of obtaining, transforming, transmitting and storing information in living nature, society and the technical world.

Apart from the need to make an early broad application of the knowledge and skills given by informatics in the other subjects on the school curricula, it is desirable to begin a systematic study of this subject as early as in forms VII - IX also because, first, a study of informatics by children of this age has proved successful both in Russia and outside it and, second, in view of the important role of this subject in the advancement of thinking processes and the formation of a scientific world outlook in children belonging precisely to this age group.

The basic course could combine the three current trends in the study of informatics in the secondary school, the trends that reflect the major educationally significant aspects of this subject:

- the philosophical aspect - formation of a systemic-information approach to the analysis of the outside world, the role of information in management, the specifics of self-regulating systems, and the general laws of information processes in various systems;
- the user aspect associated with the urgent need for «computer literacy» and preparing schoolchildren for practical work in an environment determined by a wide use of information technologies;
- the «algorithmic» (programmer) aspect which is, at present, more strongly connected with the advancement of thinking processes in schoolchildren.

The third stage (forms X - XI) would continue education in the field of informatics as vocational training whose extent and substance would depend on the student's interests and professional preferences. Specifically, the schools and classes that emphasize mathematics could introduce extensive training in computer programming and the methods of computational mathematics; the schools with a stress on the natural sciences could provide a course in the use of the computer for modeling and processing experimental results; the schools teaching mainly the humanities could give the students an idea of the systemic approach in linguistics, philology and history; rural schools could teach the use of information technologies in the organization and economic management of agricultural production, etc.

THE ROLE OF CLASSICAL UNIVERSITIES IN FORMATION AND DEVELOPMENT OF GLOBAL SCIENTIFIC AND EDUCATIONAL ENVIRONMENT

G.V. Mayer, A.S. Revushkin, E.S. Vorobeychikov, V.P. Demkin (Russia)

The modem system of education is going through the period of rapid transformation conditioned by the revolution in information technologies and their expeditious penetration into all spheres of human activity.

In this connection it is the educational environment which is becoming a central area of applying new information technologies to give a new impulse to development of the society.

The classical universities, according to their definition, have always been the centres of science, education, and culture. That is why they played a leading role in the society development. During recent years the social status of universities is considerably changing for good. The reason for this is the constantly increasing social significance of education. A society in all its spheres: social and economic, scientific, technical, and cultural, depends upon the scientific discoveries, knowledge, and professionalism. That is why the involvement of classical universities into the informatization process will have a crucial importance in the further development of civilisation.

The disintegration tendencies observed in Russia and in the states of the former socialist system sector are fostered by a historically formed situation when the academic science, the higher education, the fundamental university education, and the applied industry-oriented education exist on their own not interacting and not co-ordinating their efforts. Only at the turn of the 20th century the system of higher education has started seeing some signs of moving from a single-purpose professional training of specialists to building up a personality, enhancing the fundamental background, education humanisation, and to rising the role of classical universities. This resulted in emerging of many technical, agrarian, pedagogical universities that forces us to give a definition to a university in a traditional sense of this word, namely a «classical university».

The role of a classical university in an educational system is reflected in the etymology of its name. The Latin term «classicus» means «pattern», «exemplary», while «universitas» means «aggregate» or «collection» and is based on another Latin word «universum» meaning «existence» or «the world in its unity». Therefore, a classical university can be defined as an institution dealing with patterns allowing to orient oneself in the existence. In this regard a university has to be a new educational philosophy medium.

The educational functions of a university within the framework of this philosophy lay, first of all, in developing creativity and constructivity of a well-prepared mentality as well as in supporting motivation for educating oneself during the entire life.

The outcome of the classical university education should be an individual whose becoming would be conditioned by external influences, interactions, and internal work.

It would be wrong to think that a graduate of a classical university should not be a professional; on the contrary, he or she has to be a professional, however, not a «narrow-subject specialists» but a «generalist», i.e. a specialist in generalisation.

The success of a university as an educational institution is a great deal determined by its activities as a scientific organisation. When deciding on the scientific status of a classical university in Russia it is necessary to consider its specific position in a science sphere which is different from that in other countries of the world. The major distinction is that there is the Russian Academy of Sciences which is almost the only institution expected to be a generator of new scientific ideas, knowledge, etc. This fact cannot but influences the status of a university as a major centre of reproduction of new knowledge about nature, individuals, and society and requires its close interaction with academic institutions.

The educational and scientific functions of a university are closely associated with another important purpose of a classical university - the purpose of being a centre of accumulating and dissemination of national cultures in all their diversity constituting the basis of the world culture. In a modem society this function of a classical university is not ceasing to be important but even becoming more critical.

To conclude it is necessary to state that a university playing the "role of a centre integrating science, education, and culture has a special status among the educational institutions, its importance is hard to overvalue, and its role in civilisation development is beyond the comparison.

The technological revolution and, in particular, the breakthrough in development of technologies for gathering, processing, and transferring the information offers new prospects for development of the educational system and for its escape at an absolutely different level.

This is primarily conditioned by the technical level of telecommunications development which is nowadays allows for access to any informational resources regardless of distance, while the utilisation of advanced information technologies essentially facilitates collecting necessary data provided they are available in electronic databases.

New information technologies employing multimedia are powerful educational tools as they are capable of visualising complicated abstract concepts.

The application of latest information technologies in education has resulted in creation of a principally new form of the training process - a distance teaching. The expansion of scientific and educational space in combination with unique qualities of distance teaching and learning affords grounds for considering the latter the most promising form of education in the 21st century.

The particularly attractive feature of such a form of education is the possibility for implementation of a concept of continuous education an individual consisting in strong needs in gaining knowledge, inherent to a human being and showing itself during the entire human life. A number of other features of distance teaching such as easy access to, openness to a wide range of customers, availability of various educational programmes, multi-level education, etc. allows to have the widest population clusters from different, sometimes very distant, regions, involved in the educational process. In doing so, together with educational tasks, enlightening and bringing up jobs as well as work on dissemination of cultural heritage, etc. can be approached.

Accordingly, the utilisation of up-to-date information technologies is the key line of classical university development that will allow them to accomplish its mission of being an aggregate of social institutions.

A critical outcome of applying information technologies in educational sphere is the increase in authority of classical universities and in their role in development of the entire world community. Nowadays it is the time when the status of a university as a centre of consolidation of science, education, and culture shows itself most evidently. Accomplishing their mission classical universities provide for creation of such a scientific and education environment that is now acquiring a global nature. Their influence is far beyond the borders of regions and countries and determined by value and historical role of each specific university. High scientific and pedagogical potential, rich spiritual traditions and scientific and cultural values accumulated over many centuries are becoming available to all members of the world community aiding in the natural process of the unity of the mankind and of the formation of a noosphere - the sphere of knowledge.

SCIENTIFIC AND EDUCATIONAL NETWORK IN ALTAI AREA

V. L. Mironov, V. V. Evstigneev,
V.I. Beregovoy, A.I. Kamyshnikov,
N.V. Gorlov, L.L. Turdakin (Russia)

One of the most important trends observed in today's society is the creation of a single information environment. In the beginning of the nineties the international global computer network Internet made its start. The Internet information resources form the single world-wide information environment being supported by governments, universities, research centres, largest libraries all over the world.

Currently, Russia is also active in creating its own information environment to join the international one. Large projects are being implemented now: creation of the Federal University Computer Network (RUNNET) within the framework of the scientific programme «The Universities of Russia»; RELARN Project involving scientific and research universities of the Russian Academy of Sciences, universities and other higher education institutions; UNICOM Project initiated by the State Committee for Higher Education of the Russian Federation, and others.

The Altai region is one of the largest scientific, educational, industrial, agricultural, and cultural centres of the Western Siberia. The population of the Altai region numbers over 3 million people, about 700 thousand of whom live in Barnaul city. The Altai region accommodates several dozens of higher education and research institutes and hundreds of other educational, cultural, social, and medical organisations. The efficiency of their work and realisation of the accumulated informational potential require the information exchange that would employ the computer networks both within and outside the region, i.e. the single regional information environment.

The work is under way in the Altai region on the creation of a single information environment on the basis of the Altai regional scientific and educational network which is a segment of the Internet and serves to the needs of science, education, culture, public health care and social service of the Altai region. This network has to become the grounds for the integration of the regional information environment into the global one, for the development of the new information technologies.

The initiator and the main organiser of the network is a not-for-profit association uniting scientific, educational, cultural, health, and social institutions and organizations.

At the first stage those scientific, educational, cultural, health care, and social institutions and organizations having their own local networks and willing to combine their resources became the major information centres. These are higher education institutions of Barnaul city (classic, technical, pedagogical, and medical universities and the others), the regional administration, the regional employment centre, the Institute for Upgrading of Teachers, the Public Health Care Department, several schools - about 20 organisations in total.

The structure of the regional computer network is the combination of three-level blocks, which in future will be linked by means of digital communications.

Level 1. The central communication block located at the Inter-city Communication Centre Building (ALTAITELECOM Corporation) provides for external connections of the network members with other regions and the Internet users including international ones. Its another function is linking the information centres within the region.

Level 2. Strong points of the regional network located at the leading organizations of science, education, culture, public health care and social protection transfer the information from all the network users, situated at their territories, to the central communication block.

Level 3. The local network blocks or users's terminals provide transferring the information from the local network organizations or organization departments.

The proposed hierarchic principle of structuring the regional network is selected based on the following factors:

- clearly seen integration character of the network;
- geographic location of organisations - potential users of the network;
- minimization of expenses on communication means;
- possibilities for step-by-step launching the separate network segments;
- independence of building level 1 block and level 2 and 3 blocks connected with one another;
- available opportunities of creating regional data and knowledge bases;
- possibility for pursuing the single administration and routing policies.

For providing the network operations the association members employ the UNIX servers and the servers ensuring the operations of the local networks based on TCP/IP protocols.

At this stage the geographic, land-survey, and other information databases are being created containing the information about the entire region and some key organizations of the region.

The information database on the region contains historical and geographical information about the Altai region, the information on its scientific, educational, cultural, and industrial potential, etc. This database will be placed at the central telecommunication block in the form of the hypertext using WEB technology.

The information databases on project members will contain the brief information on each organization: historical background, description of activities, list of staff members, etc. Such databases will be placed at level 2 blocks. Thus, this information will be available all over the world that will assist in establishing closer and more fruitful international contacts.

The land-survey databases content the data on soil and climate of the Altai region districts.

In future, the members of the association will develop specialised databases on organizational, scientific, educational, cultural and other activities run by various regional organizations. In addition, the electronic catalogues of all regional libraries are planned to be compiled and included in the network information contents.

The information available in the network will be build in the form of hypertext distributed databases added with multimedia elements (graphic, photo, and video illustrations) placed at WWW-servers of the central communication block and the blocks of level 2.

The Altai region administration supports the development of the regional telecommunication environment.

All this will allow scientists, teachers, students of various educational institutions, and specialists of other organizations of the Altai region for direct access to numerous sources of knowledge and world culture, give an opportunity to introduce the region to the world community, and, in the long run, will make the Altai region a competent participant of the process of mankind's moving to the developed information society.

NEW INFORMATION TECHNOLOGIES IN BULGARIAN EDUCATION

Ivan Pankov,
Boiko Denchev (Bulgaria)

1. NEW INFORMATION TECHNOLOGIES AND THEIR INFLUENCE ON EDUCATION

In the education system (universities *and* high schools), different technical teaching means have been used to aid the teaching process and to improve its efficiency for a long time. These technical means were corespondent to the level of scientific progress in Bulgaria, as follows:

- classical means in education as: overhead projectors, epidiascopes;

- educational television;
- computer means and systems in teaching;
- first steps in multimedia and hypermedia in class-rooms.

Gradually the education gets "Informatized", i. e. the reproductive form of teaching, based on the existing educational programs transforms into interactive, by offering the students not only concrete knowledge, but access to vast amount of information sources. These new forms give students opportunities like access to extra information, simulations of processes and many more. The obvious advantages of hypermedia means in education led to their widespread application in many countries. The essence of these means is hard to define. This is a wide definition that integrates elements from several aspects:

- technical aspect: new information carriers, magnetic and optical disks, interactive television, global computer networks;
- user's aspect: combination of vision, text and sound put together accordingly in a unified system and distributed on electronic carriers, possible of interacting with several human senses.

These new information technologies put some new problems for teachers to solve. Hypermedia environment has great didactic possibilities in demonstrations, visualisation, student's personal choice of learning sequence. On the other hand the teacher has to deal with new terminology, teaching technology, and technical means.

How to start? How to achieve optimal effect in teaching while using hypermedia means? At what age to start this 21-st century education and on what basis? - These are the questions that preceded the founding of fundamental research carried out by the Bulgarian Ministry of Education, Science and Technology.

Nowadays a number of workgroups conduct research in different areas, such as:

- experimental application of multimedia and hypermedia in universities and schools;
- development of appropriate educational software in Bulgarian language;
- perspective technical means;
- organising of production and distribution of educational software.

This activity is co-ordinated by a Special Experts Council to the Ministry of Education, Science and Technology.

In process of preparation is a National Program on the new informational technologies in education. At this point are defined the following divisions:

- founding of pilot educational centres on preparing and qualification of teachers from all levels of education;
- forming teams of teachers for development of the educational contents of multimedia and hypermedia applications;
- creation of new forms and methods of teaching as: distant, in service training;
- determining the efficiency of teaching while using new informational technologies;
- textbooks in the context of new informational technologies in education.

Teams of qualified teachers have already been founded at several schools and universities to complete some of these activities. The appropriate equipment, multimedia computer stations and others, are supplied for conducting the teaching process. In universities exist development groups for adaptation, localisation and creating of new educational software.

2. CONNECTIONS WITH INTERNATIONAL PROJECTS AND FOUNDATIONS

Specialists of the Bulgarian educational system have regular contacts with their colleagues abroad in the field of new informational technologies in education. A significant part of what has been achieved is a result of co-operative activity on projects like PHARE, TEMPUS and Copernicus. The following projects from TEMPUS are of great importance to our educational system:

- JEP+ - Establishment of a Computerised information Network for Bulgarian Higher Education Institutes. The main goal of this project is to set the foundation of an inter-university computer network. In this project participate three Bulgarian universities: Sofia University "St. Kliment Ohridski", Technical University - Sofia and University of National and World Economics. Main computer network, based on optical cable, is installed at each of the Bulgarian universities and the necessary computer equipment for the maintaining network is supplied. More information on this project can be found in Appendix 1.
- JEP Interuniversity Centre of Modern Educational Technologies. Five Bulgarian universities take part in it. These are: Sofia University "St. Kliment Ohridski", Technical University - Sofia, Technical University -Varna, Rouse University, New Bulgarian University. The other participants are: The University of Plymouth and Liverpool "J. Moor" University (England) and "St. Patrick" College (Ireland). The main goal of this project is to form conditions for a constant qualification of university lecturers on applying modern educational technologies including multimedia and hypermedia. Teaching plans and materials have been developed. Main centre and local filials at each university are organised with library and software. In close time the qualification courses will develop and will include teachers in professional education. More about this project is placed in Appendix 2.
- A package of projects on using new informational technologies in teaching: mathematics, mechanics, and multimedia in universities.
- Five high schools have been equipped with "a class room of the future" for application of modern informational technologies in education.
- The optical disk factory at Stara Zagora is equipped with development equipment and production .technology for multimedia educational software.

CONCLUSION

1. The new informational technologies put higher requirements to the qualification of teachers from schools and universities. Creating adequate conditions for improving teachers' qualification in new information technologies in education is necessary as a first step.

2. An appropriate form of spreading knowledge on new informational technologies in education are demonstration centres, for their building is acceptable an idea for typical equipment.

3. Application of a complex approach in teaching in the context of the new informational technologies is an important foreground of achieving the desired effect:

- methodical problems;
- new contents of textbooks;
- individual work with students.

4. The new informational technologies offer possibilities of new forms of teaching not only in high schools and universities, but also in company education. All this supposes serious attention of state institutions on

organising a system of constant education and qualification by means of distant teaching, satellite television, etc.

Appendix 1

Establishment of a Computerized Network for Bulgarian Higher Education Information Institutes

Background of the Project
Training Needs

The essential improvement of the Bulgarian higher education is impossible without a close collaboration and rapid integration of the Bulgarian universities into the European higher educational system. An important aspect of this integration is the development of information and communication infrastructure of the Bulgarian higher education, linked to the European and world-wide networks. This will greatly facilitate the cooperation between Bulgarian and European university lecturers and scientists, and wilt provide an easy access to the information, software and facilities developed and available from various European and world information sources. The introduction of a direct communication and information links with European universities will have significant impact on the level of the teaching process due to the use of modern educational methods, training material and library services.

The development of modern computer networking facilities linking the three largest universities in Bulgaria, and its successful use in the teaching process and. other related activities call for the development of personnel, capable of managing, upgrading and further enhancing the network services and shared resources.

In order to efficiently use the Novell network and communication facilities in the existing courses, and to provide for the development of new ones, based on advanced networking and information services, the teaching staff of the universities will have to undertake network-specific training. Help and assistance with the use of these facilities in the teaching process must be made available an-site.

In order to improve the efficiency of the teaching process based on modern communication media, the university students must be aware of the basic principles and the use of computer networks. Therefore there is a need for network-specific short courses for undergraduate and postgraduate students, which should be taught on a regular basis in each of the three Bulgarian universities.

Therefore, there exists a need for specific training in three clearly identified areas:

- Training of system and network administration personnel.
- Training of university teaching staff.
- Training of students and other academic users.

Considering the great necessity and importance of modern computer networking for the development of the Bulgarian higher education, the consortium of EC and Bulgarian partner organisations have decided to join their efforts in the establishment of such a network that will link the three largest Bulgarian universities to the European network, and provide a range of activities . to meet the training needs of the target universities.

Appendix 2

An Inter - University Centre for Modern Educational Technologies

Providing a Focus for Innovation, Training, Development and Demonstration

There is a strong demand for university education in Bulgaria both from young people and, more recently, from adults seeking retraining or returning to education. In order to stimulate and support innovative change, there is a considerable need for staff training and development in a wide range of methodologies for developing and delivering teaching and learning. This three year strategic Project will provide such training for over 450 lecturers from across Bulgaria and will therefore help re-orientate the higher educational system.

The Project will initiate, facilitate and support appropriate innovative change in Bulgarian universities through the provision of high quality academic staff and curriculum development and a range of activities to encourage the use of modern educational technologies.

Through the establishment of an inter-university Centre, it will provide a focus for staff training, educational innovation, discussion, demonstration and development of teaching/learning materials which, following the initial three year JEP. funding, should become self sustaining.

Staff development will be delivered to interdisciplinary groups. Curriculum development activities will be focused upon helping staff introduce humanities into technical curricula, information technologies into humanities curricula, and introducing more flexible and open delivery techniques, including the education and training of adults.

A long term aim is to create a self-supporting and self-perpetuating service to all Bulgarian university staff. It is anticipated that support and finance will be obtained through a variety of measures including:

- charges for training courses,
- charges for consultancy and development; work for companies, in particular SMEs,
- sale of "products" to Bulgaria and other countries.

DEPARTMENT OF INFORMATICS AND COMPUTER ENGINEERING: VARIANT OF ORIENTATION

V. I. Perekatov, V.V. Shilov (Russia)

Currently one of the main problems of Russian higher school is the fact, that old job placement system (distribution system) of the graduated dies not work anymore, while the new one is only in the stage of forming. This situation is only a consequence of the changes in the society, and in the first turn economical ones.

As a result each department (and further me shall consider only departments, as structures, which directly prepare the specialists) worrying about their future, ought to find the way out of the situation independently.

These general problems are actual today also for a lot of departments, whose professional field is *computing* [1] (or, according to more habitual terminology, informatics and computer engineering), in spite of their relative privilege state.

The field, where the passed changes are mot pronounced, is financial-credit, bank and exchange activities, which provide all the infrastructure of new market economy. It appears a lot of new firms and organization, working in this directions. Old ones also are changing (such as *SberBank)*. It's absolutely evident that their activities are impossible without contemporary computer engineering technique and corresponding software, the base of which, in their turn, are bank-financial information technologies. They utilize the most advanced means and methods of computer engineering techniques and programming. This high level is constantly supported due to stable and significant investments of financial-credit institutions namely into the field of financial informatics. Banks and exchanges, currently being one of the most rich national institutions and realizing the impossibility of its effective functioning without most wide introducing of corresponding information technologies, start to form their market and dictate their market and dictate their *requirements to it. This circumstances give the base to the* presence here of widespread field of activities for specialists in the field of computer engineering, programming and a set of adjacent fields.

Not less attractive might be the market of office programmes. Such programme environments are necessary also for industrial enterprises of all dimensions and ownership types, and for state institutions and departments, and for private firms in commerce, tourism, serving sphere, and for educational establishments. Currently this market concedes the above mentioned one, that is mainly connected with the difficult material situation of many of its subjects. However, when with time duration more and more number of them would obtain firm status, they would start to take care not only about their surviving , but also about prospects of normal progressive development. But it is also impossible without maximum introducing of information technologies, connected with system analysis and organizational management.

Apart from that it's important, that above mentioned software markets in Russia are practically non-filled (this concerns mainly to office programmes) or, at least, are much for from saturation. At the same time the unique character of the most of administrative-and organizing principles, accepted in our country, makes problematic the direct utilisation and adaptation of software of well know west firms, present in the market. This factor in combination with extremely high cost of such products, which for a long time would not be available to mass user in the Russian market, is one more argument towards our choice.

Let's try to classify the interests of persons, who touch in their professional activities with above mentioned programme systems.

To the first group one can refer the employers of banks and other financial-credit institutions, which in their work permanently ought to use personal computers and social applied software. Lets call these specialists professional users. Widespread distribution of financial information technologies has called out to life the appearance of great number of such users. This group of specialists gives extremely high requirements to the fulfilment of programme systems, which namely make them one of the most sophisticated and advanced types of software. The same group of specialists may be allotted in application to office programmes (management of different level, analytic, employees of provision and sale services etc. are entered into it).

To the second group one can refer the specialists in the field of management and analysis, modeling and creation of complicated systems. They are able to analyze complex systems in absolutely different subject fields, to develop their mathematical and information models, and to project and (may be in less degree) realise corresponding software. In the orientation process of this specialist's training towards financial field or management, we shall get the experts, who are able to formulate professionally the problem, which requires the programme realization, to develop corresponding project and to menage it. Let's call these specialists as problem producers. They are able to speak, using common language, either with professional users, arranging there practical requirements into their terms, or with the specialists of the third group, which one may call designers.

The designers in our case are high educated system programmers, who are able to work on the most modem level with the use of the most modern technologies of designing and following of software. By the way, they ought to be able to freely orient in the general questions of problem field and, thus are not simply coders of algorithms, developed by producers. They are able also to estimate the accepted decisions, and even participate in there design.

What is the way (and does it really exist) to combine the training of the whole three groups specialists? Is it able to perform it in the framework of one department? Probably it's possible in principle, but doubly that it is advisable. The fact is that the first category of specialists - economists - sufficiently greatly differs from others, due to their attitude to the considered subject field. Here we mean users, not designers. Correspondingly, the volume of knowledge, delivering to them in the field of computing ought to be significantly less, while their structure - absolutely different.

The students, getting their base economic education, must hear special courses, sufficient to get the representation, concerning construction of modern financial programme systems, presented requirements to them, about problems of interface organization with the and rational methods of their solution. And already on their base it's necessary to design one or two practical courses for getting of these systems use experience.

As a result the specialists are let out - managers, economists, accountants etc. - who, coming to work, exactly know, what instruments they need to effective functioning, are able to formulate and stand up their needs against the administration and are able to interact with those, who design and follow these software, consulting with them and presenting new requirements to modification and development of software, starting from their practical experience.

The specialists of the second and third groups, complementing each other in significant degree, might be advisable to train in the framework of one department. They may go out to the market individually. But it seems that more rationally - in the case of proper and active department administration policy - to train them as whole groups, rolling them on realisation of given projects during the studies. As a result after the end of study we get a complex collective of researchers and designers, who have passed test on compatibility, solidarity, able to interact with each other and to contact with clients (in wide sense of this work). Moreover these collectives may be trained even for certain organizations, carried out definite projects.

It's well known that the educational process ought to be carried out in the framework of one of stated governmental educational standards of high school professional education. Naturally, the department may choose its own way and try to base, develop and confirm new direction of bachelor training and corresponding curriculum. However the careful and detailed analysis of the curriculum contents of corresponding' directions show, that the most wide among them and the most close to our term «computing», is the group of 552800 «Informaitcs and computer engineering». In the process of study according to this direction it appears possible not only to give the student the whole volume of knowledge in the computer field, but even completely keep all the requirements, presented by the main authoritative in the world Standard ACM/IEEE (see [2, 3]). That is why the training of the third group of specialists (designers) is rational to carry out in the framework of namely this direction. Other interesting group of specialized fields is «System analysis and management» (553000). The analysis of its educational programme indicated, from one hand, extremely closeness of its contents to the requirements, presented to specialists of the second group (problem producers), while on the other hand - a great similarity with nomenclature and even filling of certain disciplines with 552800 standard.

Thus we can see the possibility to unite the students of both groups not only in one department, but even on a lot of specialized fields in common teaching group (while on the first two years the are not divided). The specifics of groups way be reveals in fool range in a set of special disciplines, proposed to students, and facultative disciplines, beginning from the third year of education.

It's necessary to understand that along going of Russian economy out crisis, surviving of industry and science, the quantity of possible educational directions, and, correspondingly, spheres of professional applications would permanently increase. One of the most significant functions of the department authorities is namely in the ability to predict beforehand the main development tendencies, perform in time steps on the base of short term and long term prognostics. The department ought to be alive, dynamic, and developing organism and to have sufficient freedom of maneuver for correction of its course - in the framework of the declared direction and specialized field.

UNITY OF INFORMATION SPACE AND CONCEPTS OF INFORMATIZATION OF EDUCATION: REGIONAL EXPERIENCE

V.I. Ribakova, S.I. Shchukin (Russia)

The term «united informational space» currently is used in different publications so frequently, that this idea is percepted as something, standing to reason, which does not require any remarks. Along with this, the analysis shows, that this idea is system creative, and arbitrary, even not so much. from the first view, changes in its contents may lead to significant changes in the concept of informatization.

During several recent years on the Yaroslavl region territory there has been developed telecommunication network combining the institutions" of training and qualification upgrading of pedagogical staff, educational management's organs, a set of secondary education establishments. Each network user obtained the opportunity of e-mail service and participate in teleconferences of this network, the main purpose of which becomes the transfer of normative documents, delivery of letters, orders and methodic developments. The users of the network include school directors, teachers on informatics, experts of educational municipal management organs.

If one starts from comprehension of information space unity as a unity of communication capabilities, joint creative work and access to network resources, than the attachment to this network of all educational institutions may be considered as creation of united regional information space.

However widespread distribution of personal computers, development of global telecommunication networks, show-slip growth of number of scientific and educational network users, combined by Internet network, led to significant changes in understanding of opportunities to apply the computer engineering means and information process role in the society life. Currently united informational space my be presented as some public information media, into which a person gets from the early stage of his development and which follows him education, professional and any other type of activities.

Principal significance for regional informatization infrastructure development have the law of Yaroslavl region *«On the information provision of government authorities organs in Yaroslavl region»* and settlement of Governor on the policy in the informatization sphere corresponding to which it's foreseen: creation of united regional information space as a part of unite information space of the Russian Federation; widening and improvement of information infrastructure; promoting the local authorities in establishment of municipal information networks; informatization of government authority organs activities.

A significant stage of regional education was assignment of agreement between Yaroslavl region government and International Science Foundation *(Soros Foundation)* on carrying out of a project *«Yaroslavl base network»*, which foresees the creation of pilot territory computer network. This network presents libraries, schools, hospitals and high school institution all service types of information network Internet. In the framework of this project in order to deliver the access to the network for students and teachers, more than hundred computers were delivered to schools of Yaroslavl. The necessary condition, which was fulfilled during computer setting, attached in Internet, was an easy access for student's learning.

A significant addition in the project, initially oriented on urban network development, was the creation at Department of Education of new institution - Regional center of schoolchildren distance education (CDE). This center is supplied by modern technical equipment and is first of all oriented on the work with remote territories of region. This year about thousand schoolchildren would pass different types of training. The combination of distance education development and realisation of the programme *"Family computer"* ought to became a serious factor of education humanisation, significantly changing the tendencies of education sphere development.

In January 1996 the Board of the Department of Education has confirmed the main directions of regional education informatization, where as number one is set the creation of regional knots and infrastructure of telecommunication network.

A great significance for the united information space creation has delivering by Administration of informatization and technical means under Governor the possibilities of utilization of selected administration communication channels with regions about the connectiveness with Internet. If it would be possible to overcome the difficulties concerning technical equipment of regional knots, soon the schoolchildren and teachers of rural regions would obtain the access to all kinds of services of global information space.

The considered here structure of united information space should not at all be regarded as its amorphousness and structurelessness. For example, structure includes the following components of the information space:

- subsystem for information-reference service of population;
- subsystem of information-reference and analytic service of household subjects;
- subsystem of information-reference and analytic service of governmental authorities and local self-management.

In correspondence with this classification the information educational space might be regarded as combination of two tietly connected subspaces, which, however, have their own peculiarities:

- one of them combines the information resources of teaching process;
- the other one - the information about state of educational process, resources of management information.

The first of them may include either resources, created systematically for educational purposes, or any other information resources with open access. The main its feature accessibility and openness of information.

The information space of management information ought to include resources, which are created and actualised in a regular order by authorized for that optical persons, while the access to informational resources, which contain personal and confidential information, ought to be organic.

The idea of information space unity considered here renders the determining influence on the approach to education management informatization and allow to formulate the main principles of information streams and resources forming.

Forming of management information resources ought to be carried out with account of possibility to integrate multiaspect management information on each level - let it be educational institution or ministry - into united functional system, which allows to analyze the state and tendencies of educational sphere, corresponding to counter of management in interconnection of all its typical features. In context of information streams forming the unity providing means providing of programs, used the different management levels, to receive and deliver data of standard (or stated in normative-technical documents) formats.

These principles, though they seem to be evident, nevertheless not always are taken into account in contemporary practice of all russian arrangement carrying out, concerning informatization of education management. Currently into Russian education system there have been introduced and are introducing now into exploitation set of software, purposed for formation of three of formation streams:

- state and statistical account (designer of software is - Russian institute for pedagogical staff qualification upgrading);
- data, concerning children-orphans or children who have left without care of parents (designer is - Moscow State University);
- data about presentation to state rewards (designer is - Republic information-pedagogical center).

All the programs were fulfilled on good professional level, however in programs 1 and 2 the above mentioned requirements were not taken into account. This three programs, as well as data prepared using these programs can't be integrated into system of informational provision of arbitrary level.

The program *«Automated work station of chief of reword department»* may serve as an example of the problem realization, set and fulfilled with the account of above mentioned principles: it's based on widespread used data format and foresees the data enter from the file. As a result it was possible to integrate the program and data into the system of information provision of educational management of arbitrary level. The reason of formed situation is, evidently, the absence of normative documents, regulating the designs in this field and absence of coordinational center on management of informatization of education.

Currently in Yaroslavl region there are carried out active works, intended on regional system creation, for monitoring of educational sphere. This system includes information collection and analysis, gives social, demographic, phsyhological and economic characteristics of educational sphere.

The use of information systems in management would not only provide the quality of management activity increase due to operative provision by necessary information and means of its presentation, but also will give richest information about tendencies of education sphere development.

Taking into account the actuality of informational proceeding of educational management, it seems for us advisable and in proper time the creation of laboratory and opening of experimental ground for creating and including of information-analytic and modeling systems for secondary and pedagogical education. Evidently, as an experimental ground one ought to chouse a region with sufficiently developed infrastructure of informatization. Taking into account the attention, should by the informatization organs of state authorities in Yaroslavl region, constant readiness to collaboration of Analytic center and administration of informatization of regional Governor, presence of organization with high scientific potential, such as Yaroslavl State Pedagogical University, Institute of pedagogical staff qualification upgrading, Institute of Pedagogics and Psyhology, Regional center of new information technologies, opening in June 1996 of Internet Center, and also the presence of serious work already done in information system integration, our region may by chouse as an experimental ground for carrying out of works in this direction. The laboratory in the conditions of contemporary communication nets development, may present certain deversed structure with participation of experts either from Yaroslavl region, or from other regions.

PERSPECTIVE DIRECTIONS OF INVESTIGATIONS IN INFORMATIZATION OF EDUCATION

I.V. Robert (Russia)

The informatization of education process developing on the base of the up-to-date information and communication technology possibility realization initiates the activity intellectualization of both the teaching and the learning, maintains the integration tendency of a process of the cognition of the appropriatenesses of object fields as well as the surroundings (social, ecological, information, telecommucation et al.) and provides with the pedagogical influence synergism combined the firsts with the advantages both of the education individualization and differentiation. From this the realization of the possibilities of up-to-date information and commucation technologies provides with the transition from the authoritative, illustrative-explanatory methods and the mechanical learning of the factological knoledges to the mastering of the ability to acquire independently the new knowledge using the modem methods of the knowledge presentation and extraction, the up-to-date technoligies of the information interaction with the models of objects, processes, phenomena presented in the objective media as well as with their imitations.

As shown the home and foreign experience the realization of the possibilities of the up-to-date information and commucation technologies involves the educational activity spectrum broadening, the perfection of up-to-date organizational forms and educational methods as well as the beginnings of the new ones, the object field appropriateness study broadening and deepining. It causes the educational material matter selection criteria. They base on the necessity of the intensification of the processes of the intellectual development and self- development teaching personality - the forming of the ability to formalize the knowledges about of the object world, to extract independently from the knowledges, to realize the «microdiscovery» in the appropriateness study process, to use the modern information technologies as the instrument of the measuring, representation and influence on the object world.

The development of the education technologies on the base of information and communication means is determined in a marked degree by the general appropriateness which reflect the technical, technological, psychological-pedagogical as well as physiological-hygienic features of their usage what, in one's turn, leads to the nesessity of the exposure of the pedagogical-ergonomical conditions of the safe and effective application of the computer engineering means, information technologies, telecommunications provided with the process of informatization of education development at the active usage of the science-pedagogical information banks.

From this the followings acquire the special significance:

• the development of the theoretical base of the process of the sertification hardware, informaion and communication means which applied in the educational purposes;

• the consideration of the psychological and physiological-hygienic features of the informatization of education;

• the problems of the perfection of the pedagogical technologies on the base of the modern means of the information and communication;

• the problems of the development of the matter and metodical system of the the informatics teaching in the general education school and the higher pedagogical education in the conditions of the many-profile education differentiation and humanisation;

• the development of the model of the integrational educational-methodical environment of the education informatization of the «school-pedagogical university - postgratuate course» system.

The above-stated determine the following perspective directions of the investigations in the education Information field which conduct in the Russian Academy of Education in the frames of the complex programme "Informatization of Education".

1. *The development of the scientific base of informatization.* This direction supposes the investigation of the philosophical aspects of informatics, the solution of the fundamental education problems in the theoretical information science field, the development of the education informatization level estimation methods, the realization of the high professional skill specialist training for the field of the informatization of education.

2. *The perfection of the educational technologies based on the modern information and communication means.* The features of the educational technologies based on the usage of the modern information and communication means possibilities are:

• the scientific character, trust worthiness and maximally possible accessibility for the any primary sources of the information including the educational one;

• the access to the archives and on-line information, the possibilities of its processing, transmission as well as interaction with the users of the word information medium;

• the guaranteeing of the information interaction with the models of the objects, processes and phenomena as well as their imitations presented in information-object media with the fitted teaching technology elements;

• the organization of the teaching process as much as approached to the experimental-research activity which is adequate to the process of the cognition of the corresponding object fields;

• the building into the educational. systems of the possibilities of the modem information and communication technologies.

The solution of the problems of this direction assumes the investigation of perspectives of the progress of the matter, means and methods of the general education, the development of the modern pedagogical technologies based on the up-to-date means of the information interaction (multimedia, "virtual reality", telecommunication).

3. The development of the informatics teaching matter and metodical system in the general educational school and higher pedagogical education in the conditions of the information and mass communication of modern society. In the frames of this direction the scientific-pedagogical bases of the development of the metodical information teaching system in the general educational school and the pedagogical universities in the multiprofile education differentiation conditions.
4. The perfection of the basic training matter of the informatics in the higher professional education system in the conditions of the informatization and mass communication of the modem society. This direction assumes the development of the scientific-pedagogical bases of the perfection of the basic informatics course component in the professional education system in the depending from the future specialist activity profile.
5. The psychological and physiological-hygienic features of informatization of the education. The development of the psychlogical-pedagogical supporting of the modern information technology usage in the education assumes the investigation of the questions of the ecology problems connected with usage of information and communications, the development of the psychological and physiological-hygienic features of the health breach prophylaxis (including the indexes of the vital functions of the organism), including the development of the psychological-pedagogical recommendations for the projecting of the telecommunication media of the scientific-practical orientation.
6. The pedagogical-ergonomical conditions of the effective usage of the computer technics means, information and communication technologies provided the development of the education informatization process. These problems are actual because in the general education establishment the non-quality technics which is damage for the health as well as with the truncated programm-technical possibilities is often used. In connection with that the necessity of the sertification of the computer technics, informatization and communication means which are used with the general education purposes has be appeared. The last determines the necessity of the development of the pedagogical-ergonomical requirements to the computer technics and the means of the information technologies on which base the selection of the technics used in the education sphere is occurred.
7. The development of the. integrated teaching-methodical education medium model of informatization in the «school - pedagogical university - postgratuate courses system. In the frames of this direction the conditions of the multicomputer organization of the distributed network of the teaching-methodical centres of informatization of education with different levels into the common pedagogical knowledge engineering centre are investigated, the methodolodgy of the teachers and methodologists for information teaching technologies as well as the diagnostical system for the testing of the teacher's and student's training level for usage of the information technologies in both the teaching process and professional activity are developed.
8. The formation of the matter and program-methodical guaranteeing of the self-education process in the field of the usage of the possibilities of the up-to-date information and communication technologies. This investigation direction assumes the making of the

scientific-methodical base of the self-education in the field of the usage of the possibilities of the up-to-date information and communication means (in particular, on the base of the distance education, in the conditions of the home personal computer complect usage).

9. The perfection of the scientific-pedagogical banks based on up-to-date information and communication technologies. In connection with the development of the information superhighways it is necessary to investigate the possibilities of the information networks with the purpose of the guaranteeing of the technology of the acces of the different user categories to the scientific-pedagogical information bank data files. The investigation perspective consists in the creation of the conditions for the information and library-bibliogaraphy supporting of the different specialist categories in the field of the pedagogical science and practics by means of the TV acces to the scientific-pedagogical information data files promoted the development and perfection of the information infrastructure of the educational space.

The prognosis of the development of the process of the informatization of the education. The process of the informatization of the modern society and its priority directions - the informatization of education - are continually determined by the scientific-technical progress achivements which growth at present days occures literally in the exponential rate. The swift perfection of the word information medium or «the network space» *(cyberspace)* which allows to form the information stream in accordance with the interests and preferences of the specifical information user, allows to forecast the development of the pedagogical technologies based not only on the receipt of the access to the information resources (for example, the largest word libraries, TV studios, data bases) or the copies of the real historical documents but on the firsthand information interaction with the colleagues on the mutual scientific investigations and educational problems.

The foregoing possibilities allow to develop in principle the new technologies of the information interaction between the information users and reorganizers what, in one's turn, determines in principle the making and development of the new pedagogical technologies of the teaching-informational interaction based on the possibilities of up-to-date information medium.

COMPLEX INNOVATIVE SYSTEM OF ENSURING UNITED INFORMATION EDUCATIONAL SPACE IN PERM REGION

A.P. Sapozhnikov, A.G. Skripov,
N.M. Stadnik, A.N. Tashlykov,
E.K. Henner (Russia)

The programme of informatization of education, accepted in 1994 by the Ministry of Education of the Russian Federation, has stated as one of the most significant element of this process the development, creation and realisation of regional informatization programmes. One of the first among them became the programme of informatization of education in Perm region.

The work, presented in this paper, has been carried out in the period 1992-1996 by Laboratory of informatization of education of Perm region, Perm State Pedagogical University and Institute of pedagogical staff qualification upgrading of Perm region. The Laboratory creation, has promoted in significant range coordinated complex decision of informatization problems in the general education system in the region.

Scientific-pedagogical development on the theme included either scientific-pedagogical or organizing-practical part.

Scientific-pedagogical part of the work is connected with the solution of the following problems:

- development of methodic and carrying out of the development of real state in process of informatization of education in the region;
- development of scientific-pedagogical principles and model of united regional information education space;
- development of the principles of creation of regional system of information provision in the educational system with the use of either traditional methods or contemporary technical means;
- development of the form and content of training and retraining system for different categories of pedagogical staff for solution of education informatization problems on the regional level;
- development of education contents conception on informatics and computer utilization at study of different general educational and special subjects in the schools and technical colleges with the account of real opportunities of the region;
- working of policy, theoretically justified and coordinated with real regional possibilities, for technical equipment of educational system.

During scientific-pedagogical developments there was necessary to find out the ways of the following contradictions decision:

• between the necessity to form informational culture of the trainees, which is significant for further life and work activities, and traditionally formed inertial training system, in which the information technologies are practically beyond the attention;

• between the necessity of constant qualification upgrading of the educational staff in general and informational technology questions in particular and increasing impediment of this process for most of educational workers (in particular, teachers) due to some organizational and financial reasons;

• between the necessity to bring the information streams, rolling in the educational sphere (first of the all in the teaching, teaching-methodical and scientific-methodical) into correspondence with time requirements and increasing difficulties in solution of this problem by traditional methods;

• between the necessity of most efficient technical equipment of education institution and limitations, connected with financial resources, staff training level-teachers and technical experts.

The organisational-practical (inculational) part of the work consists of the following:

- creation of united management system and organizing provision of works on informatization of education in the region;
- creation of informatization providing system of general and secondary special education in the region with the use of modern technical means, creation of regional bank of pedagogic information, telecommunication system of access to this bank;
- radical changes of training and retraining system of teachers, authorities of different level education organs, other categories of pedagogical staff on the problems of information technologies in education;
- bringing of training on «Informatics» subject into correspondence with the requirements of the basic curriculum, State Educational Standard, partly creation of corresponding teaching-methodical materials, computer software.

Among the documents, with which the authors at different stages of the work have coordinated their activities, the most important are:

- Federal purpose programme «Informatization of Russia in the period 1993-1995»;
- Federal programme of education development in Russian Federation;
- Programme of informatization of education in Russian Federation in the period 1994-1995 Decision of the Council of the Ministry of Education of the Russian Federation «Concerning course of Programme of informatization of education realization in Russian Federation in the period 1994-1995»;
- Plan of stabilization and development of education system in Perm region on the period up to 2000, Perm,1995;
- State education standard of higher professional education - the requirements to obligatory minimum of contents and level of bachelor training in the direction of higher school pedagogical education (stated in 1994);
- State educational standard of higher professional education - the requirements to obligatory minimum of contents and specialist training level on the specialties of higher pedagogical education (stated in 1995). In the result of works performed in Perm region, there has been fulfilled the following.

A united system of management, organization and scientific-methodical provision of works on informatization of education in the region has been created. This system has integrated the effort both of management organs and several higher schools. In the system of regional education there has been unrolled special subdivision for informatization problem solution:

- Regional center of pedagogical information (RCPI);
- Center of computer education training and informatization of education;
- Center of informatization of professional-technical education system;
- technical service.

On the base of RCPI there has been created and now is functioning a system of complex information providing of the regional education. It includes the regional bank of pedagogical information, central knot of telecommunication network of RCPI, more than 10 regional knots.

There has been found complex solution of the problem of training and retraining of specialists on the problems of informatization of education. In this programme Center of computer education training and informatization of education and Pedagogical University take part. Regularly there are carried out:

- training and retraining of teachers in informatics;
- training of subject teachers (expert for teachers in informatics), teachers of professional-technical colleges;
- training of management-administrational staff of education system;
- training of accountants and economists in the educational system;
- training of workers of pre-school and complementary education system.

As one of first the region began the teacher's training, for whom informatics is basic specialty. For this goal there have been developed special curriculum, new course contents.

It's realizing centralized and regional programme of step-by-step equipment of educational institutions and organs of educational management by computer technique, which includes:

- equipment of as much as possible secondary schools (general education and technical) in the region by complete sets of training computer technique for providing of the first order needs of teaching process, determined by obligatory state requirements (first of all - by providing of base course on informatics teaching);
- equipment of leading in the field of informatization educational institutions by most modern technique;
- equipment by computer technique of regional education management and schools for organization of contemporary system of production and administrative management and attaching to regional system of telecommunication connection.

There have been carried out several scientific-methodical works including:

- development of the concepts of united regional information educational space;
- development of the structure of regional bank of pedagogical information;
- development of the base course of informatics for 8-9 forms of general education schools (including creation of teaching-methodical complexes and programmes of this course for secondary professional-technical education on several specialties, mostly deversible in professional-technical colleges of Perm region.

The main organizing-practical activities on regional programme of informatization of education (planning, application) are present in an unrolled form in the following publications:

1. Programme of informatization of education in Perm region for 1992-1994. Perm, 1992.
2. Programme of second stage of informatization of education in Perm region for 1995-1998. Perm, 1995.

Concerning certain of above-mentioned questions the authors have published a lot of materials in central and local scientific-pedagogical editions.

CONCEPT OF FUNDAMENTALIZATION AND INTELLECTUAL TECHNOLOGIES OF EDUCATION

A.D.Sukhanov, O.N.Golubeva (Russia)

All over the world the search is carried out for new educational system, more democratic, diverse and resulted from the society interests position. The intention to overcome the professional isolation and cultural limitation, tendency towards all-round, harmonic persons, are typical for the whole world community.

In our country on the background of deep social transformations the educational system since the beginning of nineties also is at the stage of reforming. The necessity for reforms is caused, in particular, by the fact, that in our higher school in a lot of directions there has appeared a substantial gap between the global needs of the society and the educational results:
between the objective requirements of the modern times and all-over not sufficient level of education, between the professional orientation and personal needs in harmonic satisfaction of various educational requirements, between modern methodical approach and archaic style of the teaching.

The attempts of the higher school modernization in our country were carried out several times in sixties-eighties. However, none of them resulted in serious success, since none of them had touched conceptual base of the educational system. Realizing of this fact led recently to the crystallization of *new educational paradigm,* in the frameworks of which the reconsideration of directions and priorities took place: from primacy of pragmatic knowledge to the development of common culture and scientific forms of intellectual activities, from historical context of scientific knowledge formation to the modern representations, concerning structure and integrity content of scientific system.

The new educational paradigm in Russia was gradually formed during 1990-1994 in the course of development of major directions for higher school reforming. Its major elements are presented in the guiding documents of the State Committee for Higher Education of the Russian Federation and in the Memo of "Fundamental (natural science and humanitarian) University Education" (1994) UNESCO International Symposium. The new educational paradigm as high-school educational priority considers orientation towards personal interests as adequate to the modem tendencies of community development.

The education may be considered as *oriented towards personal development interests,* if the following tasks might be solved with its help. Firstly, it's necessary to harmonize the interrelations between the human being and nature trough mastering scientific pattern of the world. Secondly, one ought to stimulate the intellectual development and enrichment of thought through mastering of modern methods of scientific cognition. Thirdly, it's necessary to start from the fact that a person lives in the society. For his successful socialization it's necessary to deep into existing cultural, and, in particular, technogenic and computerized media. Fourthly, it's required to take into consideration, that contemporary person lives in the conditions of saturated and active information environment. That is why, the educational system task is to teach a person to live in its stream, to create the background and conceptions for permanent self-education.

Today a search of the way of transition to the new educational paradigm takes place. It by no means does not reduce to pure increase the volume of educational disciplines or to increase of the education duration. The idea concerns the reaching of principally new educational level of individual person, as well as the whole society. The new educational paradigm means a tendency towards competence, erudition, creative bases and culture of person, that is namely *educational paradigm.* This is the source of the main characteristic quality in comparison with former paradigm, which was mainly *paradigm of teaching,* the main slogans of which were knowledge, skills and education.

The main component of the new educational paradigm is the *conception of fundamentalization,* which treats fundamentality as a qualitative category of education and the person's educational level.

In correspondence with the proposed concept, the education may be considered as *fundamental in the case when it presents a process of non-linear interaction of the person with the intellectual environment at which the person precepts it for enrichment of his own internal world and due to it he matures for multiplication of the potential of the environment itself.*

As a base of fundamentalization, such educational system and structure is declared, the priorities of which are not pragmatic, narrow specialized knowledge, but rather methodologically important, long having invariant knowledge, performing integrated perception of scientific picture of surrounding world, knowledge, which accelerate the intellectual blossoming of the person, his adaptation in rapidly changing social-economical and technological conditions.

The fundamental education comprises the unity of ontological and gnoseological aspects of educational activities. Ontological aspect is connected with cognition of the surrounding world, while gnoseologic - with mastering of methodology and obtaining of cognition skills.

The fundamental education, being a tool for reaching of scientific competence, is oriented on obtaining of deep, essential base and connection between different process of entire world.

Fundamental education, being a tool of reaching of high erudition, is oriented on *widespread directions of scientific* knowledge (natural-scientific, technical, humanitarian), enclosing a significant complex of closely specialized field. At the same time the fundamental education supposes mastering of mutually complemented components of *integrated scientific* knowledge. For example, the idea of fundamental natural-scientific education includes the study of contemporary technological culture, humanitarian knowledge and culture research. The idea of fundamental humanitarian education includes the study of natural history, etc.

The fundamental education, being a catalyst of freedom for creation, based on cognition and critical perception of integrated human cognition experience, on obtaining of internal personal sureness in his opportunities to use creatively transform this experience, provides the conditions to stimulate and realize the creative roots of the person.

Fundamental education, being a tool of accessing to contemporary intellectual culture, promotes the reaching of qualitatively new level of rational thinking culture, which *appears to be fruitful not only for the problems of local field* of knowledge, but also in the whole sphere of cognition activities. It appears as a result of mastering of those significant shifts, which are produced by truly fundamental knowledge in comprehension of all the science as a whole.

That is why fundamental knowledge can not be at a periphery of informational massive, mechanically supplementing it. Fundamental knowledge is rod, system forming, methodically significant presentation, ascending to the roots of understanding, to the primary essences. In accordance with the above mentioned considerations, not all educational subjects may be referred to fundamental ones. This, however does not decrease their significance for the formation of a competent person.

Corresponding fundamental knowledges are contained in all natural-scientific and humanitarian fields of scientific knowledge. However, corresponding general educational disciplines are not fundamental *ex definitio.* The educational subjects become fundamental, if they, in common, reflect adequately the fundamental ideas and presentations, logic and structure of corresponding sciences from the contemporary position.

General process of the fundamentalization of education consist of special complex organization of the content on the base of combination of epistemological, ontological, *special scientific didactic ideas, which increase the status* of educational disciplines up to fundamental level.,

The fundamental education ought to be integrated, for what the individual subjects are considered not as a complex of traditional autonomous courses, but are integrated into unique cycles of fundamental disciplines, connected by common purpose function and inter-discipline connections.

This namely treatment of fundamental education, which was proposed by Russia in the "Fundamental university education" International project, has accepted significant resonance at 28th General conference of UNESCO and founds a wide support among the world community.

Accepted in 1993 the conception of informatization of Russian higher school education may be considered as one of the means for new educational paradigm realization. This is due to the fact that it is located in fairway of new strategic orientations of high-school education system. The main task of the informatization process comprises creation of the conditions for global rationalization of intellectual activities and staff training, processing new *cultural level of thinking. The main technical and* technological base for informatization of the educational process is universally recognised computer. However, from the point of view of anxiety for the further fate of fundamental education it's necessary to point out some warnings.

The purposeful development of *informatization of the education* must present mainly, not a reaction on penetration of computer technique into industry and every day life (user's education), but rather ability realization of deep influence of *«all-round computerization»* on the mentality of a person, who lives in such an environment. One ought to take into account, that this influence may have double consequence. On one hand, it may appear such a trust to computer, concerning some operation, which under other conditions results in the fact that an educated person is not able to make by himself some simple tasks (as for example fast approximate calculations, the use of dictionary, translation to a foreign language etc). There are clearly negative consequences. On the other hand, constant but properly organized contact with *computer may, on the contrary, influence creatively,* promote the formation of new physiological structures of the person, entering to resonance with the ideas of fundamentalization.

Thus, it's necessary to direct the educational informatization in constructive channel, preventing *making fetish of computer and khakering.* Unfortunately, not always this idea is taken into consideration. Very often computer is included into educational process as the end in itself and considering it use as a symbol of contemporary educational system. In real practice on this base a substitution of the informatization idea is often takes place and it reduces to computerization.

The utilization of computer in fundamental education must be pedagogically advisable, determined by the essence of subject tasks and demonstrate it principle functional advantages and non-replacement. It must be limited by those fields of educational process, where any other approach is doomed failure. In this context one ought not to increase artificially the scale of computer control of knowledge, especially, if these technologies carry out the same *functions as a teacher, possessing in comparison* with him only better memory and patience. It should be assumed that in nearest future (in the highlight of the informatization ideas) the teacher as a person, not as a appointment, has no computer or computerized *competitors.* His role would increase permanently.

Intellectual technologies of education may be utilized in connection to all subjects of fundamental level and substantially optimize the educational process in school. Hence, in it application one should distinguish at lest two levels.

The first level combines the *teaching* technologies and has the most wide distribution. It is directed on skill mastering and their autonomization. It includes the system of the trainer type with no dependence on the type of the training skills - from pure physiological (the speed and accuracy of reaction) up to intellectual (the speed and correctness of traditional task decision).

The other level concerns the *education*, considered in the spirit of new paradigm. It contains the intellectual systems, in which the tasks are generated, that require acceptation of decisions in non-typical situations and reflection. It did not obtain a proper wide spreading yet, though, according to opinion of experts, namely this level of intellectual technologies in the most prospective for modem higher school educational tasks.

Alhoritmization of the decision acceptation process and evaluation of it optimization may be carried out for great quantity of actual tasks in the conditions of dialog work regime with the computer. Here not the mastering of particular skills takes place, but mastering of cognition activity methods, that seems to present the main problem of fundamental education (contrary to teaching). Apart from that, in a real information stream the destructive noises (hindrances) are always present, which are often comparable with constructive signal. It's necessary to develop the skill to recognize and select the true message on the background of the «noisable» one, and also to stratificate (to build a hierarchy) of received information. On this way the most important function of fundamental education is realized through the orientation and adaptation of a person in entire environment, the development of initial information system and formation of independent activities. These problems does not meet adequate solution in the framework of traditional technologies and seem to be the main directions of the intellectual technology development in the fundamental education.

In conclusion, it's possible to mention the hope, that at the threshold of 21st century real prospects appear for the new type person formation in his essence («the person skilful» - «the person intellectual»), due to the new orientation of educational systems, the person would reach the next stage of his development, which one might call «the person educated». In the evolution the key role belongs to fundamental education, carried out on the basis of intellectual technologies.

WHAT CAN THE COUNTRIES IN SOUTHERN AFRICA HOPE FOR WITH THE ADVENT OF THE ERA OF NEW INFORMATION TECHNOLOGIES? (THE SITUATION IN CAMEROON)

Alain Biloa Tsimi (Cameroon)

I. SUMMARY DATA

Cameroon is located in Central Africa, located between the 2nd and 3rd degrees of the Northern Latitude and the 9th and 16th degrees of the Eastern Longitude, and id bordered by the Gulf of Guinea.

In 1976, the Cameroon population numbered 7,663 million people, by 1990 it had increased to exceed 12 million, and is expected to reach 15,292 million by the year 2000. The annual population growth rate is 2.8 per cent; rural population comprises 55 per cent of the total population; population density is 27 inhabitants per 1 sq. km.

The Cameroon population is relatively young, with 46 per cent below 15 and only 3.1 per cent older than 65 years of age. We shall be concerned primarily with the younger population sections. Some data on these group is presented in a below.

Table 1

Pre-school Age Group of 4-5 Years (in thous)

Year	Boys	Girls	Total
1996	427	425	852
2000	467	463	930

Table 2

School Age Groups of 6-14 Years (in thous)

Year	Boys	Girls	Total
1996	1 713	1 690	3403
2000	1 814	1 833	3674

II. THE EDUCATIONAL SYSTEM OF CAMEROON

The 44th Session of the International Conference on Education (Geneva, 1994) published the official date which is cited and referred to below.

II.1. Problems

• No law on education - a basic document which would clearly formulate the general goals of education in respect of the individual and society, the specific goals of education and its various levels and forms,an answer to the question of what kind of citizen we should raise, the role of the participants in the educational process, etc.

• Inadequate differentiation of training types and trends at various levels of education against the great variety of the social and economic requirements, specifically as concerns such occupations as land and animal farming, ecology, the arts, computer science, and some others.

• Shortage and unsatisfactory quality of the educational facilities.

• Shortage of teachers in some disciplines, such as informatics, for example.

II.2. Perspectives

Several priority trends in the development of education are currently the topic of public discussion in our country. At the same time, even now when we are in the course of preparations for the convocation of the General States for National Education - seen as a "forum for discussion, exchanging opinions, and taking the decisions allowing Cameroon to accept the challenge of the future awaiting our society at the start of the third millennium and to provide proper education and training for our youth - we can still point to a total absence of any attempt to foresee this future, at least in the area if introduction and implementation of informatics in Cameroon's educational system.

The above remark is to help us understand the actual state of affairs with the satisfaction of the country's requirements in the area of new technologies - there is practically none to speak of.

It should also be noted here that the burden of economic crisis (described by the specialists in detail) and the consequences of inefficient administration of the educational system have done nothing to improve the situation.

On the whole, one might say that the countries of Southern Africa ridden by these problems will as before be incapable of surging for the future because of the lack of initiative and decisive action, which equally concerns the area under discussion here - the introduction of new technologies in management and teaching disciplines.

Now let us go back to Cameroon's education system and the informatics in Cameroon. How are they doing *in* this developing country?

Serious training in informatics is provided by only one specialised institute of higher education - Ecole Nationale Superiere Politechnique in the city of Yaoundé which boasts a high standard of the teaching programmes and quality. There are also three technical colleges, all of which are understaffed, and a few university education schemes which also experience the shortage of teaching personnel.

The private education centre is marked by the predomination of a purely time-serving approach and a great demand without adequate supply of guaranteed sound training.

Hence, we might say that the objective is large-scale and the demand is enormous.

II.3. Some Facts on the Educational System of Cameroon

We shall use here the patter of describing national educational systems offered by the International Enlightenment Bureau. Based on this, Cameroon's system of education could be broken down into formal and informal.

II.3.1. The formal educational system

The system is comprised of six levels: pre-school, primary, post-primary, normal, secondary, and higher education.

At each of the levels, and in everything pertaining to their competence, intention is displayed to combine the approaches characteristic of the two different educational systems: the English language system of the North-west and South-west provinces and the French language system, prevailing in nearly all of the other eight provinces of the country.

Below are cited some figures on all the education levels.

Summary data (supplied by the Ministry of National Education and the Ministry of Higher Education)

II.3.2. Non-formal Educational System

The system is designed to meet the requirements of specific population groups, such as, for example, those whose general education was not completed or those wishing to restore and update their training. They are educated in specialized educational institutions set up under field ministries.

This is a specific sector of education, which has also felt the impact of the general economic crisis, deserves a more detailed examination. However, as the problems of this sector of the educational system are similar to those of the formal sector, we shall confine ourselves to stating that the total number of learners in this sector is 215 160.

1. From pre-school to secondary education

Table 3

Number of Learners and Education Levels (1994-1995)

(Total number: 2 592 255)

Pre-school education		Primary education		Post-primary education		General secondary education		Vocational secondary education	
Public	Private	Public	Private	Public	Private	Public	Private	Public	Private
54.977	37.015	143.219	502.262	11.157	0	295.966	163.734	47.015	49.083
91.992		1.937.458		11.157		459.650		90.998	

Table 4

The figures supplied in Table 4 indicate the resources of Cameroon's education system

Education level	Pre-school	Primary	Post-primary	Normal	General secondary	Vocational secondary
Teachers	3.755	7	1.954	123	19.649	6.814
Schools	851	6.763	162	33	709	315
Classes	1.985	37.645	597	133	10.517	3.073

2. Higher Education

Table 5

Enrolment in Higher Educational Institutions (1994)

(Total: 42,220)

	I Yaoundé University	II Yaoundé University	Dshang University	Douala University	Buéa University	Ngaundéré University
Number of students	17,000	15,000	2,500	5,000	2,020	700

Altogether, there are 23 faculties, 9 higher schools, and there university institutes of technology.

II.4. What Policies Underlay the Development of the Educational System of Cameroon?

Without going into the content of the teaching programmes and methods, we shall explain our view of the existing problems using the facts which were officially recognized by the Cameroon authorities in 1994 and which still figure today.

We can assert the following.

The Cameroon educational system, in the shape it has taken to our day, is still affected by the same factors which had caused the 1993 reform: the economic crisis, fast growth of the learners contingent, shortage of managerial and teaching personnel, inadequate correlation between the disciplines taught and the actual requirements of the labour market.

It should be admitted, though, that the country's authorities do display a political will and intention to improve the state of affairs in education and to introduce the computer science into the management and practice of training process. This intention has found expression, for example, in the currently implemented FAC Project of automated data on general education, as well as in the assistance rendered by Canada to the Technical High School in the city of Sangmelima. Besides, the integration of the Cameroon University computer network into the global French language network that has recently taken place as a start of the REFER Project implementation opens up some promising prospects for Cameroon's educational system.

As for the infrastructure designed for proliferation of the experience accumulated in the implementation of new technologies, we must stress the significant role of the existing packet data transfer network, CAMPAC (X25), which covers most of the country's provinces. Furthermore, despite the unfavourable natural conditions (dense tropical forests, vast areas, etc.), the telephone network extends to practically the entire territory of the country.

Despite all that. the situation still brings to mind the French saying" "The more of the change, the less things change."

The situation with the introduction of new information technologies at the level of higher education is, on the whole, still unsatisfactory - and this in spite of the Polytechnic School, mentioned earlier in this Report, distinguished by a high standard of training and application software. Thus, some educational institutions are obliged to give up computer science and related discipline for the entire academic year sometimes because of the shortage of teaching personnel, while the administration of human resources is left entirely in the hands of one, "non-computerized", person.

This state of affairs in the Cameroon educational system is further deteriorated by unfavourable geographical conditions, for vast territories of the country consist of densely forested plateau (in the east) or desert plains (in the north), which prevents the extension of school education to the entire contingent of school-age children. This to a considerable degree explains, also the significantly higher school attendance rate of the other territorial areas.

Finally, it is noteworthy that the government plans contain practically no provisions for the introduction of new information technologies at the pre-school to the secondary education levels, as concerns training management and the learning process alike, although some feeble and uncoordinated attempts of their application are registered at the level of local administrations (see the section "Perspectives" of the documents relating to the 1994 Geneva International Conference on Education).

There is no doubt that, on the one hand, is precisely the introduction of informational technologies that can promise solutions to the burning problems impeding the progress of the countries in the South of Africa. On the other hand, there exist no less burning problems connected with the costs involved in the implementation of information technologies and the poor infrastructure providing the proliferation and operation of these technologies (telephone networks, telecommunications, etc.). Unfortunately, these areonly some of the difficulties. Hence the enormous scale of the problems to be tackled.

III. SOME SOLUTIONS TO THE PROBLEMS INVOLVED IN THE INTRODUCTION OF COMPUTER SCIENCE IN EDUCATION

Difficult as the situation is, we should not lose hope of overcoming all the described difficulties. New technologies, while they give rise to problems, promise some solutions as well. It seems pertinent to undertake the following.

1. In order to achieve optimization of the economic, social and educational trends, schemes and developments at the national and regional levels, it is necessary to accept the need for mastering the computer science and to set up high-level informatics courses for top administrators, which courses should include training in the subject «Informatization of organizations» work of organisations", and would therefore instil in the administrators a clear notion of the "information system" as a resource for their activities, which, in turn, could become a key factor of changes for the better in the current situation. In our opinion, this could be achieved by using the IMI courses conducted in France, but in their somewhat simplified form.
2. To ensure a large-scale introduction of the computer science at the primary, secondary, and higher education levels, we should urgently arrange and conduct a trial course of training (within one or several pilot projects) in such subjects as informatics handling of documents and the proliferation of computer science for the purpose of its introduction in the economic, social and cultural areas of our country (or our countries).Such trial courses could be conducted on the basis of a primary school, high school, college, university or some other institute of education.
3. To be able to study and preserve our cultural heritage, we must urgently create data banks (including computer data banks) in such vital areas as:
   - music (for example, collection and description by computer means of all the existing musical instruments could of equal value for all mankind as a treasure-house of knowledge and a universal encyclopaedia;
   - special and unique forms of cultural heritage (such, for example, as the "so'o" philosophical system), whose preservation is a rather complicated problem at present. If would be interesting to know, whether there exists a standard archive of the "so'o" materials. The discussion of this problem by major researchers and/or teachers could undoubtedly be very useful.

Other problems and approaches to the matter could also be considered.

In conclusion, I would like to say that the success that all of us desire so much could be attained only if the following conditions are implemented.

Concerning the countries of the South, it is necessary to:
1) encourage the most bold and original approaches in the work of administrative agancies at all levels;
2) adopt the rational and objective aspects of all and every operational decisions taken in the conduct of daily activities as the yardstick for appreciating their efficiency;
3) instil in the consciousness of the workers at the higher and other levels the understanding that new technologies are today a factor of progress, and to cultivate this understanding;
4) display will and determination, and see them as the principal factor, in the way firmly taken toward the implementation of new information technologies.

As concerns the developed countries, it is necessary to:
1) do all in our power to make new informational technologies available to all;
2) set up a "financial stockpile" for facilitating the access to new information technologies for the countries of the South;
3) develop type training programmes (for various educational levels) and a system of interrelated .methods and facilities for the introduction of these programmes in the educational practices.

EDUCATION IN THE FIELD OF HIGH TECHNOLOGY AND INFORMATIZATION. EXPERIENCE OF THE MOSCOW STATE INSTITUTE OF ELECTRONIC TECHNIQUE (TECHNICAL UNIVERSITY)

V.D. Verner, A.V. Goriachev,
A.I. Piskunov,
S.G. Poliakov (Russia)

The electronics, first and foremost, the microelectronics is not only the important constituent part of an industry but a base of the state in the whole. Obviously, the microelectronics must remain among the priority branches of Russian industry, and the reproduction of the personnel for the electronics must be one of the main purposes for Russian higher school.

The microelectronics feature is the providing with the rapid development of .new information technologies which gives the necessary impulse and creates material base for the information in all fields of the human activity including the education. At present time there is no speciality which is not included into this process. But conformably to the education in the field of high technologies, this process plays the specific role. This, on the one hand, is connected with high degree of the informatization of high technology branches that requires the adequate matter and level of the future specialist training.

On the other hand, the high technology branches are characterized by the exceptional dynamism expressed not only in the fast changing of the nomenclature of the manufactured articles, but in the fast changing of technological processes and equipment. The educational establishment with their strictly limited funding has no possibilities for upgrade of the technological base in proper time which is necessary for specialists training the in the field of high technologies.

Under these conditions it is possible to provide the required level of specialists training by means of either close collaboration with industrial works in the purpose of implementation of their technological possibilities for the education or the wide use of the programmes and multimedia means for studying the technological processes and technological equipment of the modern industry.

Thus, the wide informatization of education in the field of high technology is based upon the following factors:

1) The high degree of the informatization in high technology industry.
2) The absence in the universities of the sufficient means for technological equipment upgrade.
3) The high concentration of the qualified researchers in the higher school which allows to carry out the investigations in the field of new information technologies.

The Moscow State Institute of Electronic Technique (Technical University) has lasting many years successful experience of specialists training in the field of electronics and information science, the realization of scientific investigations in the field of high technologies. MSIET has the unique possibility for the specialists training because it is the only institute in Russian Federation which has in the its structure the State Scientific Centre of Russian

Federation, so called «Technological Centre» with the full cycle of BIS design and production technological process. In this connection, the MSIET experience on the informatization of education seems to be of some interest. The process of informatization is developed in the following directions:

- development of principles and methods of information technologies;
- development of electronic textbooks;
- assimilation of multimedia technologies;
- computerisation of libraries and publishing houses;
- development of distance education means and methods.

The implementation of information technologies in the educational process allows to individualize the teaching process, provides the accordance to the modern requirements, forms the new information culture of thinking.

In MSIET it is actively conducted the scientific-methodical works on the synthesis of the video-, audio-and text information, elaborated the computer textbooks on the course «Organic chemistry», the teaching programmes and teaching-metodical complexes with the usage of personal computers on the courses «Interactive graphical systems», *«Circuit engineering of impulse and digital devices», «General physics», «Higher mathematics», «Ecology», «Technology of instrument engineering and mechanical engineering», «Applied mechanics», «Engineering graphics», «Special materials of microelectronics», «Economics of Natural Resources», «Computer engineering»*. It is created the informative and methodical means for the distance education forms.

The upgrade of the technical informatization means in the University is carried out on the basis of the priority system that provides the highest efficiency of the limited University funding. In MSIET the following general scheme of the hardware use is accepted :

1) the pilot room of 5-6 places where the computer means it are; the above means are used for the introduction into the teaching process as well as for providing the necessary managerial aids for the preparation of teaching-methodical manuals by the lecturers;
2) the room of 12-20 places for final teaching of the students of 5-6 years;
3) the room/rooms for training of the students of the 3-4 years;
4) the rooms for training of the students of the 1-2 years.

The process of the hardware development is accompanied by its consequent displacement which is carried out as follows:

- the new pilot room is arranged with the use of some technical means (in general, managerial aids) from the working training room;
- the old pilot room is quantitatively completed up to the one for the training of specialists to the degree work;
- the old room for the training of the specialists to the degree work is passed to the students of middle courses et al.

High qualification of the MSIET personnel allows to develop the new unique education informatization means. Thus, for example, the *"Science-technology park" has* developed and now starts the production of the TV text decoders with the appropriate software that allows to realize in the short time period and with the small expenditures the information service accessible for the enormous number of user both in Russia and abroad. The service provides data transmission in TV text regime in the educational and commercial purposes directly to a personal computer or TV receiver.

The appreciable help in the education informatization process in MSIET renders the collaboration with the international societies, educational institutes and research organisations. Thus, in the University in the frames of the contract with UNESCO the special courses were organised in the field of electronics and information science, as well as the training programs *"Modern personal computer software", "Design of ordered and semiordered SBIS", "Implementation of intellectual technologies".*

As a whole, the Moscow State Institute of Electronic technology (Technical University) has the possibility for improving of the training quality of the specialists in the field of microelectronics by means of the wide informatization of the all educational process sides. Its experience my be also useful for the other universities specialized on the education in the field of high technologies.

THE INFORMATIONAL INFRASTRUCTURE OF A HIGHER EDUCATIONAL ESTABLISHMENT AS THE BASIC FOR DEVELOPMENT OF HIGHER SCHOOL OF THE FUTURE

V. N. Volkova,
A.A. Ionov,
I.V. Relina (Russia)

Information is one of the most important resources of any society, which has a profound impact on social and economic development of any state, of any person. It also has a pronounced effect on the organization of educational and research process at higher schools. In this case, it is the information *environment* that has a determining effect on both the person and the society.

At the time when the educational process is based upon the traditional forms of curricula and programmes, the centralized unified transfer of knowledge from teacher to the students is provided. This makes the control of the teaching process easier, but even the search for the active training aids not always provides the formation of active purposeful person.

The creation of information infrastructure (US) is oriented towards the formation of all-round persons. It should help the students to realize their potential in speciality and to play their own individual role in the society. It should, also help the teachers in upgrading their professional quality. Il can also play an important role in optimization of educational and research process and in the development of researches made by students in higher schools.

Creation of US can become a basis for the development of such an allocated decentralised instrument and personnel environment as *techno-polyces* and *techno-parks*. US can provide the renewal and development of interaction between the higher school and the industry, it can also help to raise the level of innovation researches and to improve the students' research work.

On the basis of the above said we-can state that the information infrastructure of the higher school can become the foundation for the development of the new type of techno-polyces, which can be named the *noo-polyces*.

It is useful for the control of the US development to present it in the form of 4 levels:

Level 1. The communication level that comprises all information telecommunication, computing networks, other technical aids. Sometimes this communication level is named *Information super-highways*.

Level 2. The informational level that includes all the information that circulates in the .telecommunication nets and is saved in libraries, research and technical information departments, in automated factual and documentary data bases with the possibility for access in electoral information allocated regime, differentiated chief servicing, retrospect searching. The information level comprises all information knowledge from all document information as the traditional school books and manuals, training materials, research and technical information, normative regulations till factual information (including the statistic information about various aspects of high school activity), normative and reference information etc.

Level 3. The functional level comprises the set of services provided for users by various suppliers (the access to data bases and libraries, arrangement of TV conferences, electronic accounts and electronic purchasing, video after order etc., all services, provides by the infrastructure, including the access to curricula and programmes, to the quality standards on specialists etc.).

Level 4. The user's level consists of users indeed. It comprises formation of information needs (that is the most difficult problem) and the rules for interaction among the students, the teachers and the collaborators with IIS.

The above classification can help us to manage and control the projects and programmes on IIS development (proposed by teachers, students and collaborators). The management and control should be carried out on the basis of the special assessment aimed at allocation of the financial, material and staff funds. The method for assessment is being developed which takes into account the degree of influence of a project upon the University objectives.

For the above purpose we suggest to use the apparatus for system analysis, i. e. the methods for goals and functions structuring, the methods to carry out a of complicated examinations, the information approach by Denisov A.A. and the authors' developments.

The stratified representation is the basis for the proposed analyse of the IIS effect on the social and economical development of a higher school. In this case the functional levels of IIS and the society are determined as the "interface" levels, that links the IIS and higher school objectives; and its connection with research institutions s and enterprises.

The methods of goals and function structuring by V.N.Sagatovsky - F.I.Peregudov, R.Akorf - F.Emery are planned to be used for the analysis and development of the function level of higher school.

The intermediate assessment of elements significance for each model level should be done by the method of pair comparison in the Saaty T. modification. For the final assessment of reciprocal influence of marked level elements the idea should be used of the Pospelov G.S. method for deciding matrixes. The values of assessments itself should be produced by means of the information approach, that allows to register both degree of the effect and the probability the effect inception. The information approach also provides to simplify expert procedure through normalizing of expert estimates after and not at the time of the expertise.

DIFFERENTIATION IN TEACHING INFORMATICS IN RUSSIAN SCHOOL

T.B. Zakharova (Russia)

The school informatics course is continually developed, its education objects, the course content, methods, organization forms are revised. Even recently the informatics was studied in the higher forms only, but at present a multistage system of this discipline study is formed:

- the stage I - the propaedeutic acquaintance with the informatics elements (the primary school);
- the stage II - the basic informatics cource (the 7-9 forms);
- the stage III - the profile informatics education (the 10-11 forms).

Let's stop in detail on the problem of the determination of the informatics teaching content in the higher stage of the general education school. For this let's refer to the general tendencies which are formed on the higher school education stage.

Recently the Russian school education system the idea of differetional approach obtains gradually increasing recognition.

Currently it is accepted to distinguish the level and profile differentiations of the education content.

The level differentiation in the education envisages the forming of the heightened levels of the material mastering based on the demands to the obligatory schoolboy training. This approach allows to take into account and develop the schoolchildren motivation, interest to the learning, creative thinking, selfdependency, efficiency, attentiveness etc.

The feature of the profile approach to the teaching differentiation is the study deepness differentiation of different education fields, that is revealed in the increase of the study time which is alloted for study of the profile school disciplines, as well as for usage of the different teaching organization forms.

This kind of the education differentiation receives the largest development for in the higher school stage. It is important to note, that in the profile teaching conditions the considerable role is also led to the level of differentiation, i.e. these are not separete forms but the mutually complementary ones.

One of the aspects of the profile education differentiation problem on the higher school stage is the criterion revealing for the determination of the quantity and orientation of the profile specialization.

The analysis of the teaching differentiation practice in the higher school education stage shaws that the main criterion for the profile differentiation at present is the structure and content of studied education field (a science or a group of sciences). Thus, one should allot the mathematical, natural science, humanities, engineering and other education profiles.

In the frames of each profile it occurs the deep study of the discipline (and number of ones closely related with it), leading for this profile, while other educational objects are studied on the minimum level allowed by the general education standard.

The profile informatics study in the secondary school has two characteristic features.

Firstly, its study in the frames of any specialization profile is obligatory for the study in higher school stage. Thus, for each specialization of school education its own profile informatics course (which may still differ by the level as well as the depth of the studied material) is created in the higher forms.

The necessity of the informatics study in the education profile conditions is substantiated by the fact, that the informatics methods and meanses are practically used in all fields of the human activity.

The informatics significance for the solution of the main school education problems, the forming of a number of the maior components of the schoolchildren personality, its contribution in the young people training to a work as well as to .the following professional education determines the necessity of the obligatory teaching to this object in the frames of the education differentiation in the higher school stage independently of the choosed specialization profile.

Secondly, it is advisably to conduct the informatics education content differentiation according to the criterion.

Proceeding from the established practics it should be developed the proper informatics cources of the mathematical, natural science, humanities, engineering and other profiles. However the content of these cources is very common from the point of view of information activity content and, on the other hand, in the frames of the same profile the training may be realized in different orientations and levels of the information technology usage. For example, in the profile pertaining to the humanities it is supposed the initial training of jurists, managers, painters, musicians, secretary-reviewers at all, which information activity has the principal distinctions.

The analysis of the information infrastructure provided with the human activity, reveals the necessity to base not on the traditional criterions of the education differentiation in this field according to the main scientific ones but on own specifical criterions of the informatics teaching differentiation.

From the point of view of informatics the main factor, that differs the kinds of human activity, is how as the information, presented in one or another forms, is organised in different computer systems, data bases and knowledge, modelling systems et al, as well as by the information processing techniques.

Thus, in our opinion, it is advisably to determined the orientations of the informatics education differentiation on the base of the information organization, presentation and processing techniques, which are used in the human activity.

We have marked out six main information structures which in that or other degree take place in all traditional profiles. On other hand, these structures are sufficiently distinguished from each other from point of view of the information activity in the frames of the same profile.

On this base we offer the system from six profile informatics cources for higher stage of the secondary school, the content of which is a further investigation.

Theme 6

INTERNATIONAL CO-OPERATION

OFEK – ADVANCED TECHNOLOGY IN SERVICE OF HIGHER EDUCATION

Michal Beller, Gila Kurtz
Ehud Or (Israel)

BACKGROUND

The Open University of Israel (OUI) is one of seven universities in Israel accredited or grant the B.A. degree. It operates on the basis of distance-learning (Appendix A provides a brief description of the Open University).

The OUI is currently engaged in a far-reaching process of integrating state-of-the-art technologies into its academic curriculum, which, until recently, has been based on textbooks specially designed for self-study. Enclosed is a brochure that outlines the current activities and projects of the Center for the Design of Distance Teaching Methods, a center that has been set up at the QUI aiming at integrating modem technologies into distance teaching.

Since 1995, the OUI has been successfully operating the OFEK project of interactive distance-learning via satellite. OFEK is one of the projects operating under the center mentioned above, and is a joint venture of the Open University, Gilat Communication Engineering and Arel - Communication and Software.

OFEK - INTERACTIVE DISTANCE LEARNING

The enclosed brochure contains a brief description of the system, which is essentially a private communication network, broadcasting by satellite, a compressed digital transmission addressed only to sites equipped to receive it.

Within one year since launching the project, the OUI has reached 100 hours of broadcasting per month. During the present academic year (1995/96), the OUI operates via OFEK nine teacher training programs and 10 tutorials in academic courses. Various organizations, including most of Israel's banks, the Postal Authority, car importers and others, are already testing the system with a view to using it for corporate training.

At present, the system broadcasts from one studio to 13 classrooms across the country, from Tel-Chai in the north to Eilat in the south. All classrooms are fitted with special equipment that includes a 1.8 meter antenna, a computerized lesson control system for two-way communication, a large screen television, and regular telephones for the two-way communication. Installation is simple and fast and does not require any communication infrastructure. The entire two-way communication is transmitted via satellite by VSAT (Very Small Aperture Terminal) and there is no additional expense for the use of public communication networks.

The OFEK system operation is closely monitored and continuously evaluated, mainly by means of its own data communication. Findings have shown that the response has been extremely favourable. The welcoming reactions highlight the advantages of the system in combining the best teacher (who is not generally available to appear everywhere) with the best lesson (because the system requires exacting and detailed preparation cut every component of the lesson) while using the best, most-advanced audio-visual aids (computerized displays, software, courseware, animation, internet surfing, video films, scanners, CD, etc.) This fine lesson is simultaneously transmitted to any number of sites and becomes a live lesson thanks to the two-way human interaction. Today interaction is based on voice communication and data communication - answers to multiple-choice questions and administrative information.

TRAINING THE LECTURERS

There are inevitable differences between a regular class and a televised interactive class. These differences must be addressed by the television teachers/lecturers, and therefore, before they start teaching they are trained to be able to do that.

The most obvious difference is that with point-to-multi-point. two-way audio one-way video broadcasting, the teacher is usually unable to see the students. Therefore, the teacher needs to know how to make the television class as immediate and personal as possible. Another major difference that a distance learning teacher must address is the emphasis that must be placed on visual learning in the television classroom. The more visual the distance learning teacher can make the lesson, the better he/she can keep the students' attention and convey the instruction. Use of photographs, graphs, charts, video, and other visual presentations enhance the television lesson immensely. In addition, to take advantage of the system's full capabilities, interaction with the class should be carefully planned ahead and monitored during the lesson.

OFEK IN 1997

The Open University and its partners will continue to broaden the range of OFEK applications and improve its capabilities. Next year we plan to set up a second studio and increase output to over 250 broadcasting hours a month. There will be some 20 teacher training programs, and more academic courses which use the system. In some cases OFEK lessons will replace the traditional textbooks and in others they will serve as tutorials.

The lessons will be received in 25 towns and villages where OFEK classrooms have been installed. In the larger towns there will be two classrooms for simultaneous reception of broadcasts from both studios.

The complementary techniques and facilities will include: a help-desk, a two-way video, individual stations whereby students can be reached at home, computerized classrooms. A brief description of these facilities is provided in Appendix B.

OFEK VERSATILITY

The OFEK system is suitable for any education or training system operating by distance learning. At the OUI OFEK serves as an effective, first-rate dissemina-tion tool. With leaning and training requirements developing all the time and the world in a state of "life-long learning," there is a drawing demand for immediate (here and now) provision of the best lessons at any location, whether nearby or remote. Lessons transmitted by OFEK can relate to any subject, at any level: teacher training, academic studies, vocational courses, corporate training, etc.

The use of satellite communication allows for the transmission of broadband broadcasts to an unlimited number of sites, without having to rely on existing communication facilities (telephones, cables, computers, etc.). The system is also characterized by its economy of scale. The initial investment, while considerable, is smaller than that required for similar systems. Once this investment has been made, more studios can be added to the central system. The installation of any number of additional classrooms involves a comparatively small outlay and the number of participants in each classroom does not entail any further expenditure.

In a world where education and training are the key to a better future, OFEK fits in as an important part of the best, most effective solution possible, one that offers the most advanced technologies as facilitators of the learning process.

OFEK IN SERVICE OF REGIONAL AND INTERNATIONAL COOPERATION

Since the OFEK system does not rely on local communication networks, its use can be extended beyond the confines of the local-national scene to two wider circles - the regional and the international.

On the regional scale, the distribution of receiving classrooms can be extended to include other countries covered by a satellite. Lessons broadcast within this periphery would be of common interest and in a language understood by all (e.g. upgrade programs in family medicine broadcast in English to Middle Eastern countries, academic courses in Spanish transmitted to Latin America, teacher training programs in English, French or Arabic for countries in Africa and the Middle East).

On the international level dissemination may reach even further and lessons would concern issues of world-wide interest. (For example, courses in international marketing, advanced courses in computer science, training programs for international corporations, etc.). Satellite coverage can be provided either through direct link-up, using the existing extensive satellite footprint, or by transferring from one satellite to another (double hop).

Both the regional and international spheres can accommodate several broadcasting centers located in different countries. Thus, one can take advantage of the best capabilities each partner in the network has to offer, for the benefit of the other partners. Such Cuper-tino is doubly advantageous: On the one hand - answers to needs shared by many are provided from outside the national boundaries; on the other - the potential target population is significantly increased. These technologies contribute towards the realization of a dream in which a student will be able to construct for him/herself a curriculum made up of the finest programs offered by major universities around the world, each a leader in its field? without ever having to budge from his/her home town or place of work. The world will become a still greater global village.

Appendix A

THE OPEN UNIVERSITY OF ISRAEL

The Open University of Israel (OUI) was established in 1974 as a distance teaching university and is accredited to award the B.A. degree. The teaching method is based on study material which replaces face-to-face lectures, on tutorials that consist of discussion, repetition and expansion of the studied material, on assignments and common final examinations in a course held at the same time for all students. The course units are written by leading scalars and experts and adapted for self-study by teams of assistants, editors and graphic artists. Tutorials take place in small groups of up to 20 students, at 110 study centers across the country. Students can choose between two types of tutorial - one based mainly on self-study and a tutorial meeting every 3 to 4 weeks; the other model is based on intensive tutoring of up to three weekly hours.

In order to earn credits for a course (usually six), students must submit a minimum number of assignments and pass the final examination which takes place at the end of the semester for all students of a given course. A bachelor's degree requires 108 credits (generally this means some 20 courses). The OUI grants degrees in Life Sciences, Natural Sciences, Mathematics, Computer Studies, Humanities and Social Sciences. In Social Sciences there are dual-discipline programs which sometimes require more credits (up to 115). Students may enrol in one or more courses (3-4) per semester; they may thus graduate after three to four years.

The bulk of OUI study material is presented today mainly in book form. However, the University is currently exploring a variety of new technologies which it may integrate into its curriculum.

Telecourses - courses in which video films are the main component.

Multimedia - a combination of audio, video, data banks and animation, with a personal computer, for interactive study.

CMC (computer-mediated communication) - allowing for contact between student and tutor or between a student and his peers, for the purpose of discussions, team work, queries etc.

Informatics - learning through the exploration of data banks with the most advanced tools of retrieval.

Satellite communication - allowing for interactive distance learning.

Some 23000 students are currently enrolled in 400 OUI courses every semester - a figure equivalent to 10000 FTE students. Thanks to an accederable rate of development –17 %, annually during the last eight years - the OUI has grown more than threefold (250 %) during that time. This rate of expansion becomes even more remarkable when we consider that it occurred without an increase in governmental support (which is about 22 % of the OUI budget), and was entirely funded by tuition fees which are the same as in all other universities in Israel.

Appendix B

ADDITIONAL CAPABILITIES OF THE OFEK SYSTEM AS OF 1996/97

1. Help-Desk

A support center located near the lecturer at the studio and operated by assistants who can dispatch immediate answers to any question. The help-desk will be put into action whenever the number of participants exceeds 200, or at the teacher's discretion. Participants can address the center either by phone (directly or through voice-mail), by electronic mail (using a special PC installed in every classroom) or by fax. All communications with the center will be via satellite, at no extra cost.

2. Two-Way Video

The ability to see participants in the remote classrooms and show their picture in the other classrooms. The return picture will be of the quality known in video conferences. Thus, a teacher can be better informed of what is happening in the classrooms. This facility will be installed in some of the classrooms (the economic and operational reasons).

3. Individual

Now that the satellite "Amos" has been launched, the system may be converted to the advanced DBS (Direct Broadcasting Satellite) technology. This technology makes it possible to install individualized reception stations at a very low cost. Such stations could be established at schools, community centers and even in students' homes.

The same lesson delivered to all regular classes will appear on a TV screen or the personal computer. Return communication will be to the help desk via the public networks (telephone or E-mail) at the caller's expense. Thanks to this technology, the number of participants can be increased and most of the target populations can be served at their own locations, including their homes. They will be able to take part in the same lesson that is transmitted in the classrooms, although in their case interaction with the teacher will be somewhat restricted and involve paying for the communication.

The technology also opens up other options: communication with the "learning teachers' rooms", programmes for handicapped children, programs - including academic studies - for particularly gifted students, programs for designated sectors.

4. Computerized classrooms

The possibility of linking up with computer classes that teach computer literacy, applications and courseware, with full interaction, either by using existing means or through the computer. This system will also allow for access to the internet from all.

CONTRIBUTION AEGEE-EUROPE TO ICEI

Reinout Dekhuijzen,
Alex Ootes (AEGEE)

THE EXPERIENCES OF AEGEE: GLOBAL NETWORKING PUT IN PRACTICE

AEGEE, an independent student network active in 170 university cities in Europe has actively experienced the progress of the information society in it's association. As most members are university students, they were amongst the first to have access to the new facilities like e-mail and Internet. The network quickly discovered the opportunities these new communication technologies offered. The establishment of listservers and www-pages has improved the internal communication and external PR substantially. Today the network maintains about 450 www-pages and several mailing lists. A www-search on the keyword AEGEE gives about 30.000 hits.

Especially the listservers have greatly enhanced internal communication, since they are used for the preparation of meetings. Thanks to the listservers the general discussion is not only limited to the four annual meetings of our association, but it is continuing on a day to day basis. The coordination of the European bodies of our association has been enhanced substantially. Physical meetings are due to financial constraints only possible once every two months. The emergence of new technologies has allowed us to communicate on a day to day basis about on going projects and activities.

The biggest problem, however, is that certain parts of our network are excluded from Internet access. Some universities do not allow network access to their students, and this limits the progression of our network into a truly virtual society. The parts of the network that are excluded from Internet access miss out on most of the news and discussion. They are probably amongst the first victims of the long announced class difference between the information-rich and the information-poor.

This problem is partly solved autonomously over time since sooner or later most universities allow Internet access to students. The information society develops at a large pace, which leaves certain universities behind.

UNIVERSAL ACCESS

The previous example shows opportunities and challenges the development of the information society may offer the educational system. If universities start cooperating in global networks, the universities with the worst access will loose out in the global society. Therefore the issue of universal access is an issue of the utmost importance. We consider an *independent study on the minimum access requirements* that allow universities to stay in touch with the recent developments of great importance. These minimum requirements could be defined in the sense of what is required to allow regional differences to diminish instead of to increase as a result of the introduction of new information technologies.

However, these minimum requirements are not static and this would complicates this study. Nevertheless, we consider the definition of some kind of minimum standard of access as useful, since it can identify the real problem areas.

These problem areas are not limited to the usual underdeveloped areas. Some areas of the most advanced nations are deprived from network access. In our network, for example, most mailing list are run from Estonia, whereas most of our French network is still deprived from even the most simple Internet access. This illustrates that the division between information-poor and -rich is not necessarily bound to the traditional boundaries of rich and poor.

SCALE INCREASE

The new possibilities for scale increase in higher education can lower the cost of education substantially. This will allow less developed areas to offer world standard higher education via the use of distance education systems. Since the marginal cost of education will be only bound to the cost of the technical equipment, the use of distance education systems will widen the scope of high quality education. This does not necessarily mean a loss of diversity, since a lot of fields of study were to small to be carried out on a local scale. These become feasible on a global scale, thanks to the scale increase reached by new technical means. This may allow students in smaller education institutions a greater possibilities to specialize.

INTERNATIONAL HEURISTIC OLYMPIADS AS A WAY OF DISTANCE CREATIVITY TEACHING

A.V. Khutorskoy, E. M. Nikolayeva (Russia)

The main objective of our school is development of personally-oriented heuristic type of teaching. It comprises the realization of internal teaching potential of pupils through generating of an individual education trajectory in all educational areas.

The level of creative capacity realization depends upon the scale and the character of an information environment and the way of activity within this environment. We believe that the most productive educational environment is the phenomenon which is made by the children themselves in the form of their personal creative achievements. In this case an educational technology is presented by heuristic teaching in various manifestations.

The priority feature of heuristic teaching is its capacity to transform the traditional conception of education. According to generally accepted didactic scheme the learner first assimilates the past experience, "gets knowledge" and only afterwards applies them (including those obtained in a creative way). It is accepted that the "knowledge increment" can take place only after recognition of what is known. At the same time, knowledge from manuals and text-books is just accepted as non-personal, dependant of voluntary author's opinion or ideology, dominating in the society. At the heuristic approach the "extracted" knowledge is essentially personal, as a learner creates it anew on the investigated field of reality.

Meanwhile, the explored or extracted knowledge is not the only result of the learner's education. With the help of a teacher the educational product which was •obtained by a pupil (e.g. idea, question, definition, rule, problem, hypothesis, experiment, text, handicraft, drawing etc.) is then compared with culture and history analogues and, as a result, this product is reconsidered or completed. The knowledge and experience increments remain personally-oriented in this case.

Sometimes this increment is of wider significance as it is principally new or can be compared anyway with existing generally accepted knowledge. Our experience of heuristic methods application in teaching shows that approximately 7 percents of creative works performed by pupils of average level are 'worth considering by specialists in corresponding fields. One of the efficient forms of the elaborated teaching type is an heuristic Olympiad (Contest). It is aimed to give to the pupils an opportunity for maximum creative self-realisation with regard to their individual capacities. The pupils' achievements at these Contests are the stimulus for their further creative activity, both individually and in co-operation with the pupils from other schools and countries. Let's consider some aspects of development of programmes and organizing of the heuristic Contests that we have revealed from our own pedagogical experience.

1. Every Contest task includes a "meta-object" primary sense e.g. key concept, category, phenomenon or other object which concentrates rather wide area of cognized being and comes out of the frames of common school discipline. This primary sense gives an opportunity for every pupil to realise the cognition process in his (her) own way and to create the original educational product. The examples of such contents: space, time, movement category, concepts of number, letter, pitch, elements, world of nature.

2. Accomplishment of such Contest task includes an application of a "meta-way", e.g. some universal heuristic cognition method or problem solving, for instance: revealing of some regularity; imagery representation of the object, creating of actions algorithm. Every Contest task is carried out on the basis of leading types of activity, i.e. logical, imagery, construction or others. With the purpose of providing maximum revealing of pupils individual capacities all the Contest tasks set covers the main types of teaching activity.

3. Concerning the contents of the heuristic Contest the priority tasks are those connected with creativity of the personal educational by a learner (and not just giving a predicted answer or getting of already known solution). Thus, at the Contest the quality of the product is estimated but not the correctness of task accomplishment.

4. On the basis of the established "primary senses" and "meta-ways" the main nominations are formulated for the Contest: *"Idea"*, *"Image"*, *"Challenge" "Regularity"*, *"Law"*, *"Sign"*, *"Symbol"*, *"Experiment" "Construction"*, *"Handicraft"*, *"Composition"*, *"Algorithm"*, *"Programme"*. The diversity of objects and themes is considered as a necessary component of the Contest tasks. For example, the "Image" nomination task may contain both mathematics type of question (drawing image of number "5") and nature sciences question (picturing the image of *Spring*).

5. The participants results are estimated according to a total mark that is gained in every age category. Separately the totals on every nomination for all participants are summarised. In this case, the maximum mark for every nomination should be equal for all age categories of participants.

The heuristic Contest consists of several stages. Pupils from various schools work within their own schools and in distant communication way with pupils from other schools and countries. The heuristic Contest stages are as follows:

- Inner-school heuristic Contest on the basis of tasks made up by teachers.
- The same Contest through electronic mail is offered for the pupils of another school.
- At this stage heuristic tasks are elaborated by the pupils. Then they offer these tasks to other pupils, i.e. first inside their school, then for the pupils of the school they communicate with.
- On the basis of heuristic Contest results the participants define for themselves the most interesting themes and problems. Every pupil chooses one or few essential themes together with partners or opponents to incorporate them into his further activity.
- The heuristic activity of pupils and teachers then continues at the stage of the joint educational projects development and accomplishment. As a result of this work one more heuristic Contest is conducted. The tasks of this Contest are determined by the previous experience.

We have only preliminary experience of leading the heuristic Contests in our own school and the experience of joint Contests together with US Perry L. Dreu School (Highstown, N.J, USA). In future we are planning to continue organizing the heuristic Contests in Russia and abroad. We are inviting for co-operation schools and organizations, which take an interest in this project.

NEW INFORMATION TECHNOLOGIES IN CONTINUOUS ECOLOGICAL EDUCATION

L. A. Kokhanova (Russia)

Development of computer technology in Russia resulted in necessity of its implementation within the system of continuous ecological education. Real possibility arose for carrying out appropriate pilot research within the frames of international project.

The basic premises of the programme. There are some important peculiarities in the process of information product creation starting from the basic idea to its real implementation. We present here the training course of ecological management for municipality officers of Russia and Ukraine and in the future of other countries. The basic form of the above course is distance learning, and this is the first peculiarity of the presented course. The second one is as follows: the process of learning is intended to adults who need special knowledge.

The course is organized by International Council of Local Environment Initiatives (ICLEI) together with Russian partners. «EcoInform» co-ordination group is arranged under the Institute of World Literature of Academy of science of Russia and the Union of Russian cities. The programme is established by European commission (DG-1 - General Directorate for International Political Communications, TACIS) and supported by Ministry of Environment Protection of Russian Federation.

ICLEI as international organization is not far-famed in Russia. This ecological organization is lately established. It is associated member of International Union of Administrations. Now this organization has more than 200 members being representatives of local public authorities and its associations all around the world. In Europe 87 cities and regions and 8 associations are the members of the ICLEI. The Union of Russian cities and some towns are also the members of this Council.

The ICLEI objectives are as follows:

- Carrying out the functions of international centre for steady progress, development of both ecological policy and local ecological programmes;
- Arrangement of researches and development of new methods for ecological problems solving together with local authorities and their associations and carrying out appropriate campaigns;
- Guarding of interests of local authorities in the sphere of ecology, supporting their activity in the direction of steady progress and environment protection.

This international organization carries out the following interesting programmes:

«Climate protection» (development of the project for decrease of carbon dioxide content in the air of cities), «The problem of ozone layer», « Local agenda for XXI age and steady progress» (modelling of steady communities), the «Town protects climate» campaign is carried out; the meetings of local authorities representatives are organised, the conference on development problems of cities and towns is carried out.

Through ICLEI activity International Training Centre is established for development 'of reference books, manuals, guides and methods, for organizing training courses and for carrying out seminars, workshops, conferences and exchange of experience. ICLEI and its divisions create principally new communication field through computer networks.

«ECOINFORM» is the Russian partner of ICLEI. It developed ecological databank which is widely used by the specialists in the field of environment protection.

The pilot project distance teaching ecological management is one of directions of ICLEI co-operation with Russian partners. The main objective of the project is development of the method for distance teaching, investigation of its peculiarities and priority features, assessment of its social value.

Programme contents. The presented course includes lectures (in Russian) on ecology planning, on institution structures, on financial mechanisms of ecological management, on methods and means for cooperation with environment, on methods and means for economic and administrative control which is used for ecological policy implementation and on the issues of population partnership in the process of ecological management. The course is intended for training of adults. Its material is based upon issued by ICLEI reference book on improved experience of ecological problems solving the countries of Central and East Europe .

The listeners use the programme material according to the local conditions and carry out practical exercises on practical implementation of each theme. The material is composed in such a way that during the study the trainee must analyse environment conditions in his region, town, to study it through both popular publications and official documents and write his own essay on the above item. Not only the analyse of the problem is of great importance but also the process of finding the ways for its solving by each trainee.

How the training process is carried out? The trainees are working persons and during the training they go on working. The training materials are sent to them by means of e-mail and it provides possibility for training at a work place, to organize constant experience exchange and co-operation.

The idea of community of the trainees accompanied by individual approach to a trainee is the major one for the course. Half the battle of each individual training comprises constant communication and co-operation of trainees.

Each of 8 themes consist of 40-70 pages of training text and practical examples. Each training material includes the following divisions: main text, list of additional literature, specific examples of problems solutions, specific material on Russian and Ukrainian ecological problems; control tests on the theme.

The training materials on the given theme is sent to the trainees by e-mail once in three weeks.

Who are the participants of the programme? The programme was firstly intended to administration officers and officers of local authorities. The members of the programme are the representatives of Vladimir, Ekaterinburg, Kazan. Korolev (Moscow region), Krasnodar, Kursk, Neftekamsk, Nizhni Novgorod and other Russian cities. The chief managers of local authorities of various levels, representatives of non-governmental organization, journalists and scientists and other specialists who are interested in the environmental protection take part in the extension training course.

When choosing the members for pilot team the preferences were given to those trainees who has already graduated from universities, who has skills and possibility of work with PC and modem connection (or can connect to modem). The terms of training are stipulated in the contract on the training signed by the trainees and programme management.

The knowledge of English is desirable for participation in the above programme as it can help both the trainees and the programme managers. Language barrier is one of the most essential obstacle on the way of development of analogue programmes and courses.

Expenses and financial support. The training is free of payment for those trainees who passed selection exams. Nevertheless, municipal and regional authorities sponsor expenses connected with work time liberation, travelling allowance transportation, computer hardware and telephone payments. The fact that a lot of managers supported both the programme and its participants suggests the increase of attention to eco-logical problems and growth of understanding of necessity for continuous education. Local authorities take proper account of the fact that some trainees cannot afford monthly e-mail subscription. In some cases the trainees are supplied by modem and computer programme.

Completion of training programme. The ecological management programme will be brought to completion by the exam in Moscow. Those trainees who successfully complete the course will receive the diplomas, and the most advanced pupils will be awarded by the bonus allowing to afford the participation in International Conference in Western Europe.

COMPUTER-AIDED LEARNING OF NEW CIVILIAN PROFESSIONS FOR RUSSIAN OFFICERS DISCHARGED FROM THE ARMED FORCES

Jan Paolo Marello (TACIS bureau)

Over the past two and a half years, almost 16,000 former active duty Officers of the Russian Armed Forces have been re-trained by Russian Universities, where they learnt to draw up business plans and forecasts, so as to better fit expectations of potential employers, but also to become able to set up and duly run their own business. These forecasts, including information on expected sources of income, business financial costs as well as of servicing loans, should help them to demonstrate how do they intend to make an enterprise viable.

This Project, run by the Russian State Committee for Higher Education of the Russian Federation, with the support of EU TACIS Programme, is widely based on the use of modern teaching techniques, such as Personal Computers, in order to reach the optimum learning ratio, and also to provide discharged Officers with a precious working tool, surely indispensable for today's business operators: the Programme's goal is to enhance the former Officers' employment opportunities by providing them with new management skills that are still relatively rare at the moment.

In order to reach such a goal, a wide use has been done of PC and modern learning techniques for the Officers' courses, as it had been previously done during the initial upgrading and the following specialization of up-to 600 Russian University teachers, which took place mainly in Western Europe, at venues across Italy, France, Germany and Greece and provided them with the necessary know-how to become course instructors, methodological course developers and career counsellors.

For the implementation of this Project a number of leading West-European Companies were involved, such as Elea-Olivetti and Isvor-FIAT (Italy), Sodeteg-Thomson (France), GOPA Consult (Germany) and Infogroup (Greece), having a great experience in the field of human resources training and re-training.

After upgrading, Russian teachers went back to the 15 Regional Centers, located all-over Russia, whose roster and curricula have been drawn up to meet both servicemen discharging plans by the MoD and regional development criteria, and started running courses for Officers, duly adapting them to the concrete scenarios of every single area. This originated an important re-configuration of the didactic programmes, which is still now ongoing, so as to continuously fit real needs, which are changing together with the Country economic situation. In order to allow Centers to perform teaching activity in the best way, all of them were duly equipped with modem PC techniques, computer classes suitable for implementing business games, and multi-media techniques as well.

Now, when a greater number of Officers has undergone re-training directly at the Centers and at their subsidiaries, the experience of these Centers is being focused on the development of a more advanced teaching pattern, namely distance learning based on mobile teaching units: this system allows Centers to reach those remote military garrisons where both Officers and the members of their families experience more difficult an outplacement, and which are not in a position to send their cadres to undergo a re-training process based on traditional classroom lessons at the Center venues, also due to the great distance and to service needs in the military units.

Someone's of the Centers already have a good experience in this kind of teaching: just to quote a significant example, the main Center, located at the Moscow State Aviation Technology University (MAGTU) already in 1994 implemented a similar mobile teaching system for the Officers of the Russian 14-the Army in Tiraspol'-Moldova (the relevant Agreement was signed with today's Chief of the National Security Council, General Alexander Lebed, who was at that time the Commander of that military unit).

Nowadays those Centers which already have some experience in this newest teaching technique are putting their skills at disposal of all the other Centers, so as to achieve better results in the overall Project implementation activity. Such an exchange of experience and skills is being done in the frameworks of a joint methodological group together with experts of the European Union.

Last but not least, the Project activity is aimed, especially in this third year, at establishing an effective link between every Center and the relevant surrounding economical and entrepreneurial network, so as to facilitate the civilian reemployment of Reserve Officers, formerly belonging to the permanent cadre, particularly in small and medium-scale enterprises; by achieving this goal the Project will contribute to sustainable economic development in the different regions of the Russian Federation by providing economic life with a new wave of managers, having both the reliability of servicemen and a basic knowledge of market economy topics.

EUROPEAN INFORMATION WEB ON INTERNATIONAL RELATIONSHIPS AND REGIONAL RESEARCHES

V. G. Mashlykin (Russia)

At the third International Forum of the International Academy of Informatization in Moscow (November 1994) the supposition was expressed that the unsatisfactory use of the « in formation weapons and unjustified escalation of conventional means of warfare were the strategic reasons of the defeat of the USSR in the «cold war» with the West. The way out of the information isolation is the thought out policy of informatization, and in particular the creation of «information bridges» with Western countries. This can be regarded as one of the means of solution of the problem of the security of Russia. One of such «information bridges» is the European Information Web on International Relations and Regional Research (EIWIR). This is a large multiple-objective system, including in particular the most important field, that is education.

The project of the Web is being carried out by a large group of international and national European organizations: UNO, European Union, research centres in Germany, France, Italy, England, Switzerland, Holland, Greece, Sweden, Finland, Czech Republic, Poland, Hungary and, certainly, Russia.

The creation of the Web has two objectives - strategic and practical. The latter is realized in everyday activities.

THE STRATEGIC OBJECTIVE

It is known that in the West of Europe the active integration processes in economics, politics, in the solution of security problems and in other socially important fields are under way. Eastern European countries are being involved in these processes. It is also known difficult or even sometimes impossible to make reasonable decision in economics, politics, especially in security, if there is no authentic and timely information. To solve the problem all-European integration on a large scale is essential. That is the strategic objective of EIWIR. It should be emphasised that what I have in mind is the integration of Western and Eastern European countries. By the way, the integration in techno-field is easier to realize in comparison with more politisized fields of integration, i.e. in economics, politics, security, etc. Various intellectual, technical and monetary resources of the participants of the project are integrated in the process.

The practical objective of the all-European integration is the regular exchange of information in two-sided and multilateral international relations. In this case not only modem automated access is made use of, but also the exchange of traditional printed materials. Automated means include access by telephone on-line and e-mail, the exchange of magnetic and compact disks (CD-ROM).

It is important that the project of the Web stipulates the exchange of information on a noncommercial basis although paid services are not excluded in the future, at least in some sections of EIWIR.

In descriptions of automated information systems four main components are usually singled out, that is "information filling" hardware and software, linguistics and at least orgware.

INFORMATION FILLING

The basics of the given system consists of automated data banks (ADB) or data base (DB) both facto-graphic and documentary or bibliographic. Facto-graphic DB includes factual information about organizations, meetings, conferences, various macroparameters and also personal data about political figures and scientists. Bibliographic descriptions of printed publications predominant in DB of EIWIR remain.

HARDWARE

Working complexes of existing technical means are accepted as its basis. These are various computers, large computers are used in information centres, personal computer as a rule by personal users. There are international and national telecommunications webs, means of e-mail. Typical examples are international webs Internet, German Into-netz, French Minitel.

SOFTWARE

In EIWIR it is recommended to use the widespread packages of the software MS-DOS, Word 5. 5, Word 6. 0, protocol X-25, etc.

LINGUISTICS

The developers and the participants of the Web should talk whenever possible in the unified "machine" language, that makes it necessary to use unified labels, the rules of construction (organization) of machine arrays of information, the rules how to exchange these arrays. For the purpose multilingual thesauruses are being developed and certain accepted standards are applied.

ORGWARE

Orgware acquires great significance in the development of a complicated international system including many European countries. The Workgroup including the representatives of all the countries participating in the Web and subsidiary technological workgroups were set up for the development of EIWIR.

Russia is represented in the Workgroup by the author of the given message from the Institute of Europe (Russian Academy of Sciences). The Institute plays the role of co-ordinating organization. The Workgroup determines the partnership in EIWIR, the structure of the Web, discusses and makes basic decisions as far as technical, financial, personal and other problems are concerned. The Workgroup holds regular conferences (in 1992 - in Italy, Aricha and in Germany, Ebenhausen; in 1994 - in Sweden, Stockholm. The conferences are also scheduled in France, Greece and Russia).

Under the project the users of the Web can be educational establishments (universities, academies, colleges, etc.) Ministries of foreign affairs, parliamentary and governmental structures, international organizations, research institutes, mass media, various associations, for example, the Russian Association of European Research whose activities are co-ordinated by the Institute of Europe.

The Web of EIW1R was developed in stages from 1993 till 1998, further work is carried out when required. In spite of the fact that the Web is not completed yet, its separate sections are already operating. For example, there is an established exchange of information between the Institute of Europe and some of the partners in the Web: The Council of Europe in Strasburg, France; The Information Center of NATO in Brussels, Belgium; The Fund of Science and Politics of Germany; The Institute of International Relations of the Ministry of Foreign Affairs in Italy and some others. The Institute of Europe regulary receives by e-mail the information on security issues from NATO's headquarters center, exchange printed publications with other partners mentioned above.

There appear regular issues of «The reports of the Institute of Europe» and other materials on various European problems, including economy, politics and security.

The development of the EIWIR Project and the material maintenance of the accompanying organizational measures is carried out mainly at the expense of the budgetary funds of the organizations-participants. The necessary additional financing has been made so far by the Council of Europe, The Fund of Science and Politics (Germany), The Institute of International Relations of the Ministry of Foreign Affairs (Italy) and the SIPRI Institute in Sweden. In 1993 - 1994 the total expenses were approximately 0,5 million ECU annually. One can feel that further additional material investment is necessary as the work goes on. For this purpose the Workgroup has accepted a special resolution asking the acting and potential partners to provide additional financial support for the EIWIR Project.

Many aspects of the EIWIR System are dealt with in retail in the brochure by V.G. Mashlykin «The European Information Web on International Relations» published in the serial «The Reports of the Institute of Europe», Moscow, 1994, and also in the working materials on the given project which are available in English in the Institute of Europe.

LEARNING NETWORKS AND INTERNATIONAL CO-OPERATION IN LATIN AMERICA

Jose F.Silvio (CRESALC)

1. NEW TECHNOLOGIES AND LEARNING SITUATIONS

Learning implies transforming data and information from various sources into knowledge. These sources include: information reservoirs where information is stored (libraries and institutions that are accessible to the learner), other people (professors, students, friends), and experiences and personal encounters of the learner. There are two types of learning situations: an isolated individual consults sources of information and performs different tasks based on his/her experience and personal encounters and 2) an individual communicates with other people and groups for the purpose of learning. Both of these situations have occurred repeatedly for centuries in human history, and learners have used various means of learning, ranging from the most rudimentary ones to the most sophisticated.

What happens when informatics enter the scene? The learner finds a means of extending, multiplying and diversifying his/her learning capacity through a more effective and quicker mechanism that takes over those burdensome and routine tasks and creates conditions that encourage creativity. The ability to reproduce and simulate reality allows the learner to diversify his/her personal involvement and experiences. What happens when telematics enter the scene? The individual broadens, multiplies and diversifies his/her learning capabilities by communicating with others, on one hand, and by using various different sources of information from many geographical locations, on the other hand. At the same time, the individual multiplies and diversifies his/her possibilities of exchanging experiences and realizing personal encounters on a virtual space that extends the boundaries of reality. The development of Internet, as virtual space for the exchange of information, knowledge and communication, has brought new dimensions and challenges to traditional systems of education. It offers new alternatives, on the one hand, but seriously threatens to destroy their bases and the meaning itself of the learning process, its conditions and contexts, on the other.

2. COMPUTER NETWORKS AS LEARNING TOOLS AND LEARNING SPACES

Learning through communication naturally brings us to networks, particularly telematic ones. There are two aspects of learning and networks that constitute two sides of the same coin: network mediated learning and learning networks. Network mediated learning entails action taken By an individual or group of individuals to transform data and information into knowledge via services and resources provided by a network. An individual can take part in network mediated learning without the existence of a learning network. He/she can rely on the sources of information and communication available through Internet, for instance, to design a personalized learning program. Learning networks are comprised of people who communicate with each other and with electronic information reservoirs. Here, both information and communications services and resources have been especially created and designed for educational and learning purposes and are backed by an entire community of educators and learners. Such is the case with communities established on the basis of electronic mailing lists, newsgroups and information reservoirs offered on Gopher and World Wide Web services. But, learning network requires people who are willing and anxious to learn. This is why, in order to optimize learning network potential, it is important to develop skills needed for network mediated learning in individuals.

Learning networks have developed rather significantly on Internet over a short period of time, specially throughout the United States where 47 networks of this type exist (Harasim, 1995). A significant role is also played by some other 24 community networks, generally represented by the Freenets. While these may be more general than the aforementioned and may attempt to simulate the entire spectrum of community life to include each and all of its activities, they do include educational activities, offer learning resources and have even developed organized programs to facilitate learning in some cases. The Open University in the United Kingdom recently established a teaching-learning network based on its experience in distance education; the Fern University of Berlin has also developed similar resources. Sweden and other Scandinavian countries have had comparable experiences, but none of them as comprehensive as networks in the United States. Internet's rapid growth has provided the necessary infrastructure and made it possible for these networks to blossom, along with other social networks aimed at different purposes in other areas of social life. However, the situation in so-called "Third World" countries is different. While Internet has experienced significant growth in these countries, it has not had the same impact as in developed countries (Bournellis, 1995). Internet has embedded itself in the framework of already existing and unevenly distributed telecommunications structures and resources world-wide, which are but a true reflection of the virtual world.

3. THE ROLE OF INTERNATIONAL CO-OPERATION

International co-operation acts as an integrating element of network mediated learning situations, and its action can be further optimized through telematics. Co-operation is also a factor in formulating and incorporating policies, technology, educators, learners and socio-economic and cultural development factors linked to the teaching-learning process. Policies provide the general framework for action. Technology establishes the means and methodologies needed to solve problems and bring about change. The actors involved apply methodologies and implement policies. Co-operation, in fact, implies working through networks and combining efforts to share resources and complementary expertise. Co-operation also helps channel the socio-economic and cultural consequences of policies. People and organizations involved in networking have a natural tendency towards establishing relationships based on co-operation and benefiting network members through mutual exchange.

UNESCO has been involved in two recent and important initiatives which could be very relevant in terms of learning networks development. The first of these is the UNITWIN Program, aimed at promoting cooperation among scientists and academics for educational and research purposes. The second is the "Learning without Frontiers" Program, more specifically linked to learning networks and distance education. The UNITWIN Program began in 1992, and its objectives include the development of co-operative networks for teaching, research, and the exchange of information and knowledge in every scientific and academic field. While these networks were not really conceived as telematic networks for communication and information management, they are potential candidates to become virtual communicates of researchers and teachers, if electronic information and knowledge management and communication is introduced (UNESCO, 1995). As of 1992, an Interdisciplinary Co-ordination Unit, under UNESCO's Division for Higher Education and Research, was established for this Program, and a decentralized action throughout the world has been undertaken for the implementation of several projects, involving several regional offices and centers, like CRESALC in Latin America. The "Learning without Frontiers" Program hopes "to establish a world-wide distance education system with dissemination in every language and discipline and access to all possible communications networks. Radio, TV by Cable or Satellite, electronic mail, etc., shall offer uninterrupted transmission of formative programs in all languages and disciplines" (UNESCO, 1993). A Co-ordination Unit for this project was created at UNESCO Headquarters in February, 1996.

4. EXPERIENCES IN LATIN AMERICA

In the Latin American context, UNESCO began an initiative in 1993 through its Regional Centre for Higher Education in Latin America and the Caribbean (CRESALC) that brings together the objectives of the UNITWIN and Learning without Frontiers Programs. With the co-operation of the Universidad National Abierta (UNA) in Venezuela, UNESCO formulated a Distance Higher Education Innovation Project, whose principle objective is to evaluate, promote and introduce the rational use of new information and communications technology in distance higher education, to train facilitators, and to generate pilot experiences based on the application of this technology (UNA, 1995). The multiple aspects of this objective gave rise to six subprojects aimed at:

1) creating and developing an Innovation Network for Distance Higher Education (RIESAD);

2) training facilitators and innovators;

3) publishing material on excellence in distance education;

4) conducting research;

5) supporting the project designed to detect distance education needs in Central America, and co-ordinating the project.

The RIESAD network ties all of the activities included under each subproject together. Universities in Argentina, Brazil, Colombia, Costa Rica, Cuba, Ecuador, Mexico and Venezuela comprise the network, as co-ordinated by the Universidad Nacional Abierta in Venezuela. The network's computer center connects all of its founding institutions with each other and has contributed to progressively developing various information and communications resources, such as mailing lists and a World Wide Web server providing information on both the network and distance education throughout the Latin American region. Nationwide activities have been conducted in different countries, and institutions representing countries other than its founding members have been incorporated thanks to the network. The network has been used to organize various events, research and evaluation projects in new distance education technologies, and multimedia distance courses through Internet. The most noteworthy aspect of the network is its potential use as a resource for learning, research and the promotion of international co-operation (Chacon and Gonzalez, 1996).

Another initiative worth mentioning is the liberoamerican Network for Informatics and Education (RIBIE), which is not sponsored by UNESCO, but has co-operated closely with the RIESAD Network in various projects and activities and has been supported by UNESCO through its Intergovernmental Informatics Program (PII). RIBIE was conserved as an idea and strategic area of the CYTED (Science and Technology for Development) Program of the liberoamerican Cooperation Institute (ICI) in co-operation with national agencies from each Member State (throughout Latin America and the Iberian Peninsula). Its objective is to improve education within the liberoamerican context using new information *and communications technology. It was formally* established in 1990, and since then it has concentrated on fostering projects for multilateral co-operation in educational informatics to meet the needs of each participating country and on using this area as a strategic element to assist in the educational and social development of these countries. It likewise promotes scientific, technical and methodological training by enabling promotion and organization of events and courses aimed at disseminating results, experience and products of research on information and communications technology applied to education. Given their scope, one should mention the role played by RIBIE in organizing two *liberoamerican Congresses on Educational Informatics*, the first of which was held in the Dominican Republic (1992) and the second which took place in Portugal (1994). A third Congress is scheduled for July, 1996 in Colombia (RIBIE, 1996). RIBIE is currently comprised of experts and institutions from 12 countries, namely: Argentina, Brazil, Chile, Costa Rica, Dominican Republic, Guatemala, Mexico, Nicaragua, Panama, Peru, Spain and Venezuela. RIBIE's basic communications resource is its electronic mailing list called RIBIE-L, which provides a vehicle for all of its members to communicate and schedule activities. RIBIE-L has become a of specialized discussion forum where informatics applied to education is concerned.

On an Interamerican *scale, mention should also be* made of the Regional Consortium for Distance Education (CREAD), which was created in 1990 and whose main headquarters are at Pennsylvania State University in the United States. It is backed by the Canadian International Development Agency (CIDA), the OAS, and the Interamerican University Organization (OUI). This Consortium functions as a network for all practical purposes and was created to foster and facilitate exchange between institutions and programs involved in distance education in the Americas. International conferences and courses on the topic of distance education, attended by representatives from 50 institutions and 100 experts, have been organized through CREAD. CREAD has co-operated closely with RIESAD and has participated in jointly organizing several training courses on distance education.

These three networks complement one another. RIBIE is broader than RIESAD and CREAD in coverage of educational levels and methods, but more specific where learning contexts are concerned. RIBIE centers more on applying informatics directly to education, regardless of level and method, and RIESAD and CREAD on telematic applications given their expertise in distance education. In other words, RIBIE provides learning elements to individuals in a context involving interaction with computers, while RIESAD and CREAD function within a communications context through Internet. RIBIE constitutes an example of a network using Internet to manage and co-ordinate international co-operation projects aimed at promoting learning through computers. RIESAD is a multiple-function (learning, research and management) network dedicated specifically to the field of distance education, just like CREAD.

Through its UNITWIN and Learning without Frontiers Programs, UNESCO is conducting activities in Africa and Asia similar to those already mentioned, but they have not yet become as extensive as those in Latin America. The latter could very well serve as a source of inspiration to other regions of the world.

5. CONCLUSION: STRATEGIES FOR NETWORK MEDIATED LEARNING AND LEARNING NETWORKS

International co-operation in this area, on a more general scale, must work towards defining and fulfilling its principal objective of developing strategies to promote adequate integration of policies, technology, and teaching agents involved in the educational process and the socioeconomic and cultural impact of the new information and communications technologies (NTICs). On a more specific level, international co-operation must conveniently situate itself in Cyberspace and help bring people together to develop learning networks with participation from numerous organizations that will make learning available to anyone, anywhere, at any time, and at any age, and thereby emphasize the value of active and collaborative learning and the ability of Computer Mediated Learning (CML) systems to support the full range of human cognition and social relationships based on the principle that the improvement of society is tied to the Concept of lifelong learning (Harasim et al., 1995, p. 241). The basic electronic media of learning networks should include electronic mail, bulletin boards, mailing lists and Internet Relay Chat facilities, given their potential use as vehicles of communication between people; as World Wide Web service providers; as multifunctional services providing access to other unifunctional telematic services, and as information resource co-ordinators of the vast virtual library constituted by the Internet network of networks.

Furthermore, international co-operation must provide a proactive environment for teachers and students to master NTICs needed for people to communicate with each other and with information reservoirs, and for teachers to develop learning capabilities by communicating with other people and social groups and seeking out and transforming data into information and knowledge contained in Internet's vast and extensive information reservoirs known as virtual libraries. This should be another function of learning networks in Cyberspace. However, one should note that the presence of international organizations in Cyberspace has been rather timid compared to that of other nongovermental and business organizations' involved in education. Thus, emphasis should be given to encouraging any initiatives on the part of these organizations geared towards their incorporation in Cyberspace within the framework of learning networks, as well as to efforts on the part of other organizations and people, especially from Third World countries, who are clearly at a disadvantage in terms of developing those so-called information superhighways now servicing the new information and knowledge society.

TRAINING OF PERSONNEL IN ELECTRONICS AND INFORMATICS AT THE INTERNATIONAL UNESCO COURSES IN MOSCOW STATE INSTITUTE OF ELECTRONIC TECHNIQUE (TECHNICAL UNIVERSITY)

Yu.I. Volkov, A.I. Piskunov (Russia)

Moscow State Institute of Electronic Technique (Technical University) (MSIET), founded in 1965, is located in the city of Zelenograd which is the largest center of electronic industry of Russia. MSIET is an educational institution, specialized on the preparation of the specialists in the field of electronics and informatics.

With the purpose of maintenance of opportunities of professional growth of the teachers, science officers, specialists and students on the basis of contract UNESCO and MSIET within the framework of Intergovernmental programme on informatics in MSIET are organized courses on preparation and retraining of the staff in such areas as electronics, system programming, computer technologies, artificial intelligence, CAD LSIC (Computer-aided design of Large-scale integrated circuit).

Using the financial support of UNESCO, the own material and personnel resources, teachers were developed the curricula of preparation and retraining of the specialists on following directions:

- Designing of FC-LSIC (full-custom large-scale integrated circuit) and SC-LSIC (semi-custom large-scale integrated circuit);
- Information systems in management;
- Modem software of personal computers;
- Application of intelligent technologies, but also programme of courses:
- Designing of FC-LSIC and SC-LSIC;
- Information systems in management;
- Modem software of personal computers;
- Basis of the theory illegible multitudes;
- Introduction in genetic algorithms;
- Neuron network and neirocomputers.

These curricula provide a high modern level of preparation of the specialists in the field of electronics, informatics and communications. At half-year of activity on International UNESCO courses on computer science and electronics more than 60 specialists have passed the training. The special popularity courses *"Designing of specialised LSIC on the basis of base matrix crystals"* used, the purpose of which is study of area of application and methods of designing specialized LSIC on the base of base matrix crystals (MC), main types of their designs and library elements, but also practical mastering of a technique, route and means of BIS design. The contents of a rate is oriented to students of the senior rates, post-graduate students, teachers and engineers-developers, specialized in the field of application of element base of modern microelectronics for designing of the microelectronics equipment. The training under this programme will be carried out on the base of unique research-and-production complex - State Scientific «Technological center» with complete cycle of technological process of designing and manufacture of CCMOS (Clocked complementary metal-oxide-semiconductor integrated circuit).

Besides the traditional forms of education on the courses is practiced of the making of short-term seminars with the purpose of acquainting of a wide sections of the interested persons, including representatives of an industry, with modern achievement in the field of new information technologies. So together with representative of firm IBM East Europe/Asia Ltd. a seminar «*Advanced information technologies and modem computer architecture*» with presentation of the newest models of computers of firm IBM carried out.

With the purpose of assistance to an exchange of achievement in th e field of nformation the International courses UNESCO had organized section «*pplication of information technologies*» within the framework of All-Russia conference «Electronics and Informatics-95» (on November 15-17, 1995, Moscow).

As the humanitarian education is one of urgent directions of modern education, with the courses of assistance of International UNESCO on electronics and informatics in June 1996 an International scientific conference *"Urgent problems of humanitarian education on threshold of 21st century»* was carried out, within the framework of which work of special section *«Humanitarian problems of information technologies»* was organized.

The further co-operation MSIET and UNESCO in sphere of information will be developed in following directions:

- strengthening and development of educational center on training of the specialists;
- stimulation of work in the field of new information technologies;
- assistance to development of the new modern educational programmes and methods (including use of technologies multimedia and virtual reality) with further duplicating them in national higher school;
- development of joint international educational programmes;
- development of information system on educational services in Russia and abroad;
- development of consulting system in the field of international educational projects;
- assistance to development of co-operation in scientific researches of CIS countries, EC and developed countries.

Developing successful experience of work, the International courses of UNESCO on electronics and informatics direct activity on making mutual understanding, partnership and co-operation between Russia and representatives of international community with the purpose of expansion of opportunities of professional growth of the specialists of different countries, promoting of realization of the right on freedom and development of the person of the students of Russia and abroad.

THE INFORMATION TECHNOLOGIES IN AESTHETIC AND HUMANITARIAN EDUCATION: RUSSIAN EXPERIENCE AND PERSPECTIVES OF INTERNATIONAL CO-OPERATION

Yu.V. Yakovets (Russia)

On the eve of the third Millennium, along with hard transition of human world to post-industrial society the key factor becomes a continuous education on the basis of new information technologies, being extremely important for humanitarian and aesthetic education. This principle statement can be confirmed by several arguments.

1). The post-industrial civilization bears a *humanitarian and informing character* and composes an educational society. A highly-educated Man-creator, continuously filling and renovating his knowledge and skills . and with quick adaptation to impetuously changing world is moving in the forefront of society. The turnpike way of overcoming the keen contradictions of transition period is a formation 21st century generations on the basis of continuous training grounded on creative pedagogy information technologies.

2). In a period of formation of post-industrial society a *structure of training* and its priorities are changing. The paramount significance acquires humanitarian and aesthetic education, promoting the understanding of conformities of society development, the accepting the multinational cultural heritage, skills, habits of democratic communications. As a displacement of «a man of economics» of 21st century and «a computerized man» of 21st century goes «a humanitarian man» of 21st century. A new Renaissance.of Art [4] is explicating, an interest to high culture is surviving on the basis of its synthesis with high technologies and civilized economics. The role of adult's education is of great importance for their adaptation to changing life and labour conditions.

3). In the sphere of international relations this is *humanitarian co-operation,* that acquires major significance, especially in the area of education and informatics. This is caused by both formation of global cultural, educational and information space and acuteness of the main contradictions of a transitional epoch: a rapidly growing gap between a minority of rich and a majority of poor countries (from 1987 to 1993 the gap in production of GNP per capita in 10 most rich and 10 most poor countries had increased from 37 to 44 times). It's impossible to overcome this nearly critical gap without radical raise of educational level for people in poor countries on the basis of information-humanitarian co-operation.

In Russia during one and a half decade the intensive search of efficient ways of information technologies utilization in education is underway. Let us consider some results of this search.

1. The concept of *continuous-cycling training* (with its wide informatization) as most important feature of modern global revolution in education is formed. A key role is defined for continuous education training and informatization in formation of post-industrial society, in educational and information revolutions and in transfer of the cultural and educational inheritance on the basis of cycles-genetic conformities to the following generations.

2. There was elaborated the *purposeful programme* «The modern information technologies in art and education», aimed at realization of the above mentioned concept according to Russian conditions and formation of post-industrial society. This Programme includes the sets of Projects on the following trends (sub-programmes):

«Art production» comprises the production of video-movies, multimedia discs CD-ROM, laser videodiscs, holography on the art, museum, cities, history and other subjects;

«Electronic galleries» comprises the creation of a network of education, museum, travelling and other centres for showing, purchasing, leasing of art production, servicing of training process, organizing of aesthetic education of children, youths and adults;

«Arttelecosmos» comprises the elaboration of TV-programmes and information networks on Art and Education; the arranging of TV bridges and teleconferences;

«Art education» comprises the organizing of regional systems of continuous aesthetic training on the basis of a network of electronic galleries and cycles of TV-transmissions;

«Art ecological monitoring» comprises the development and use of monitoring technologies, protection and preservation of museum values and architectural memorials;

«Art economics» comprises the arranging of organizing economical realization of projects and programmes, arranging of conferences, seminars, exhibitions, personnel training.

3. In October 1991 *«Art Masterpieces» International Consortium* was established by the Decree of Council of Ministers of the USSR, dated 14.01.1991, for development and carring out the programme. The participants of the Consortium are as follows: The State Tretiakov Gallery, The Museums of Moscow Kremlin, The Academy of National Economy under RF Government, Mosbusinessbank, Ural electromechanical plant, «Quart» JSC, «Olivetti», and others.

The Consortium rendered a vital service in receiving an exempted loan in the amount of roubles 3.5 billions (according to the price of 1993-1994) for fulfilment of the projects by means of conversion military experiences. The Consortium organized a number of international exhibitions and conferences. It co-ordinates the activity of electronic publishing houses on marketing, art products selling, it takes part in international cooperation.

4. Under the Consortium support several Projects were accomplished in the area of informatization of Art and Education:

- the CD-ROM discs «Hermitage», «Russian Treasures» («Intersoft»), «Moscow Kremlin», «Faberge», «Petergoff» and others («Cominfo»), «Museums of Russia» («AIR»), «Modern Art» («Artinfo») and others are issued;
- the laser discs "Menshikoy Palace», «Russian Icon», «Child's portrait» ("Russian Video», «Avangard» and other);
- the series of video-movies over museums, cities, histories and other training subjects («Quart-0»), palaces and suburbs of Petersburg («AVN», «Positron»), Moscow Kremlin (Museums of Moscow Kremlin, «Artvideointernational») and others are issued;
- the electronic galleries were elaborated in the Academy of People's Economics under RF Government (1993), Kirov City (1994), in the House of Russian Science and Culture (Berlin, 1995), in All-Russian Show-Centre (1996);
- the exhibition were held in Geneva «Columb-92» (Russian pavilion), in Petersburg, april 1993, «Information technologies in Art and Education» (Session EBRD); in Moscow, November 1994, STG, «Museum-94», at information conferences, in April 1995, in Geneva, 1996 «Eurotech-96», in Brussels, 1996;
- the International conferences and seminars «Information technologies in Art» (November 1993), «Multimedia in Art and Education» (October 1994), «Ecology, Conversion and Cultural Heritage» (November 1994), an International Children's Holiday «Art and Ecology - for generation of 21st century» (01.06.1996) were held.

5. In co-operation with involved organizations, the Consortium proposed a number of projects in the field of Art and Education, for which the investors are under search:

- the preparation and production of multimedia cycles «History of Civilization» and «Bolshoi Theatre Ballet» (Projects were awarded by Diplomas of Winners and premiums of venture projects Competitions in April, 1996);
- the establishing of a network of training electronic galleries in Russia and abroad;
- the establishment of International TV-Academy of Art and Education (on the basis of TV-channel and several companies from Petersburg);
- the provision of technical base for modern electronic publishing house for humanitarian and aesthetic education.

The accumulated experience allows to make the following perspective recommendations:

1. Taking into account the key role of education on the basis of information technologies in overcoming of contradictions along with formation of post-industrial society to recommend to UNO and UNESCO to declare a *World Decade of Education and Informatics*, and to prepare the long-term national and international programmes for this direction, attracting the peculiar attention to international support for educational programmes in poor countries.

2. To elaborate in a framework of UNESCO the long-term international programme «Information technologies» in a system of continuous humanitarian and aesthetic education, using therewith an accumulate in Russia and other countries experience. This programme would include the following:

- the elaboration of a concept of continuous humanitarian and aesthetic education in a period of formation of post-industrial society;
- the determination of subjects sets; draw up curricula and methods of utilization of information technologies in pedagogy;
- the manufacturing, translation and multiplication of art production series (multimedia discs, laser videodiscs, video-movies, holograms and so on) according to selected subjects and themes;
- the formation of a network of educational electronic galleries, national and international centres for their establishment; providing the art production and service;
- the establishment of International TV-Academy of Art and Education, accompanying with a network of national TV-studios; propagation of TV-programme cycles and their international exchange; arranging of TV-bridges (of a type of «excursion» through space); introducing to Internet, national and local information network of information flows in humanitarian and aesthetic education;
- personnel training: teachers:producers for manufacturing of art production and TV-programmes, managers of electronic galleries;
- providing the support of UNO, UNESCO, international charity and. educational foundations for peoples of poor countries in realization of projects.

The International Consortium «Art Masterpieces» is ready to participate feasible in elaboration and realization of indicated programme and its separate projects, beginning from the concept preparation.

The Second International Congress «Education and Informatics» may cause a mighty pulse for formation of national and global systems of continuous training on the basis of creative pedagogy and information technologies, a development of international co-operation in this area, that will promote the formation of 21st-generations, adapted to the conditions of humanitarian-information post-industrial civilization.

LOGICS, INFORMATICS and EDUCATION

ANALYTICAL CLASSIFICATION IN LOGICS AND INFORMATICS

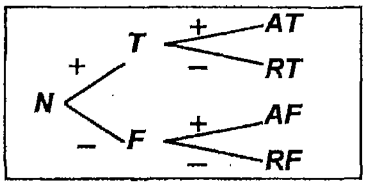
K. I. Bakhtiyarov (Russia)

The problem of classification arises along with drawing up of ordinary and computer catalogues, in patterns recognition and technical diagnostics. The common features of those problems brought to origination of questionnaire theory, the fonder of which became a French mathematician K. Pekar [1]. Most completely a questionnaire **can** be presented by matrix description. The majority of familiar methods are the methods of directed enumeration, where the number of subsets under consideration appeared to be greater than the number of elements of initial set. In general case a labour intensity of methods depend on a dimension of problem exponentially, while in case of effective algorithms - polynominally [2].

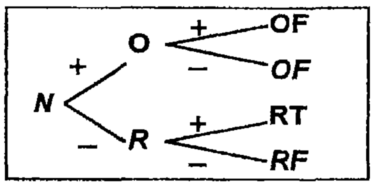
Exclusively tree-like structures are used along with informatics catalogues creation. The management in majority of companies is also organized in tree-like manner. The tree as-structured reflects the particularities of systems of subordinate links *(subordination)* in hierarchy of structure levels. On dichotomous classification the element of upper level of subordination is connected with two elements of lower level.

One can build up a tree of *theoretical* classification, in which the concept of the first level *truth* (*T*) and *false (F)* is partitioned concept of the second level. However, an investigator usually does now known the values of truth, but possesses only with their estimations: *accepted (A)* or *rejected* (*R*). Therefore, from a *practical* standpoint another type of tree is more preferable:

Theoretical classification



Practical classification



The concept *uncertain (U)* can not be at the same level of hierarchy with *truth* (*T*) and false (*F*) , that would be a logical mistake, known by the name «jump and division» The situation of uncertainty correspond to *ignorance T or F* and is a concept of zero level, which is divided by concepts of the first level. A situation («a *cat in a sack»)* corresponds to expression of *«heads or tails»*, but not assumes the existence of the third state - *«a coin is at an edge»*. The next level of hierarchy is composed by: *AT*- accepted truth, *RT* - rejected truth, *AF* - accepted false, *RF* - rejected false.

The simplicity of hierarchy systems returns with the significant drawback. The first inconvenience consist of necessity to go consequently through all levels of hierarchy for reaching the highest level. The second inconvenience of subordinations is that in replacement of hierarchy system it needs to be restructured. The transition from theoretical to practical classification it is required to break the former hierarchy and substitute it by a new one. To provide the simple and direct access between any system components it is necessary instead of different systems of *subordination* to pass to a single system of *co-ordination.*

Let us present it in a form of table with two inputs:

Estimation/truth	*truth*	*false*
accepted	*AT* - accepted truth	*A F* - accepted false
rejected	*RT* - rejected truth	*RF* - rejected false

The formation of a new knowledge passes consequently through four stages: *RT, AT, AF, RF* (clockwise index). In the theory of errors *RT* and *AF* are called, accordingly, error of the first kind and error of the second kind.

As a unique example of the whole book with the specially introduced table-structure was the «Non-formal Introduction to Algol-68» by Ch. Lindsy and van der Mujelen, published over 20 years ago (Russian publication of 1973). The book my be read «along the lines» and «along the columns» of matrix *(l,f)* depending on intents. Yu. I. Manin has named this as *«the great enterprise»* [3].

The writer A.Bitov had composed the table of content for the book «The teacher of symmetry" in a form of a table of English verbs tenses. Following his example we try to compose the catalogue of our latest works:

	Perfect	*Indefinite*	*Continuous*
PAST	The logical game of L.Carroll for computers	The paradoxical efficiency of mathematics	A universal characteristics
PRESENT	The cycles and mass data in logic from informatics standpoint	In the nets of paradoxes: an output search	A model of perpetuity
FUTURE	Interactive Carroll's diagrams	A vector approach in quasi-array logic	The analytical classification in logic and informatics

The first two articles were published in the newspaper «*Informatics*» (1995, [1] 23, 36). The name of the book is precipitated by the bold-face type, including all (published and unpublished) articles of this cycle.

An example of the relations system of co-ordination type can see a system of direct access (a recording on a magnetic disc in a computer), which had replaced the system of sequential access (a recording on a magnetic tape). The physical time is a system of sequential access, while perpetuity is a system of direct access. The co-ordination net is a visually exhibited in a form of geometrical diagrams, but this method is not applicable for the cases of more, than four aspects. That is why L. Carroll used for resolution of poly-sillogisms the method of tress (that was not published at author's life, and there is no Russian version till now). It was issued in the second volume «The symbolic logic» (L. Carroll - N. Y., 1977). In recently issued book of V. Svetlov the trees are used for resolution of syllogisms. For this, one needs, first of all, to find a mean term of premise of syllogism (incoming to both premises), and then to provide the following requirement: «The obligatory term for a proper structuring of syllogical tree is the mean position of excluding term, approving to be a linking chain» [4]. The analytical presentation of radical inference in the form of many-dimensional logic vectors allows to get rid of fulfilment of limiting terms.

To provide the direct access to any components of the system it is necessary to pass from different systems of subordination to single system of co-ordination. Such are logic diagrams, on which L. Carroll had demonstrated clearly the ties of logic problems with a problem of classification. The striking efficiency of Carroll's diagrams in comparison with Euler's circles is based apart from positive and negative cells on the use of blanked cells. It is natural to designate by zero this situation of uncertainty and the lack of information. Logic is a qualitative theory, and therefore, apart from the value 0 (lack of information) there are two another basic values: an assertion is called by integer +1, a detail is coded by integer -1. False is minus-truth, that is less than simply nothing. In this case only a computer will accept on default *«do not know»*, but not false (that would be equal to presumption of quilt). The introduction of logic vectors would allow to reduce the accomplishing of conclusions to arithmetic operations with their components and to realise a computer analogue of Carroll's logic game [5].

The premises and conclusion we shall denote by vectors, consisting of triples *(x, y, z)*, where the first number concepts a term x, the second number - a term y, the third number - a term z. Then the obtaining of a logic conclusion reduces to exclusion of term-agent *«y»* (an average term of syllogism). The positive vector *(«reality»)* corresponds to partially-affirmative inference, but negative vector *(«chimera»)* corresponds to generally-denial inference. If it's denoted: x = scientists, y = people, z = mortals, then a positive vector +(1,0,1) will concept a partially-affirmative inference *I x z* = "some scientists are mortal", but a negative vector-(1, 0,-1) - generally-denial inference *Ex z'*= "none of scientists is immortal". The two these vectors add up to generally-affirmative inference *A xz*= «all scientists are mortal".

The vector approach allows to reduce conclusions to operations with components of logical vectors. In vector concepts the syllogism *Barbara* will put down as:

«All people (y) are mortal (z)» = Ayz = Iyz & Eyz = +(0,1,1) -(0.1,-1)

«AII scientists (x) are people (y)» = Axy = Ixy & Exy = +(1,1,0) -(1,-1,0)

«AII scientists (x) are mortal (z)» = Axz = Ixz & Exz = +(1,0,1) -(1,0,-1).

In conclusion, we obtain a positive vector as a remainder (1,1,0) - (0,1,-1) = (1,0,1), but a negative vector -as a sign of sum of components of negative vector -(0,1,-1) - (1,-1,0) = -(1,0,-1). On solving the problem of decidability of syllogisms the decide role plays the *principal of annihilation* - the conclusion succeeds from premises, providing only nulling on adding or subtraction of vectors. Note, that unlike Aristotle, at Carroll *at the expense of including the negative syllogistics* the 624 modules can be derived. In particular, we obtain syllogism *Cumestres* (where U z y = E z y):

«There are no Pegasus (z) without wings (-y)» = U z y = -(0,-1, 1)

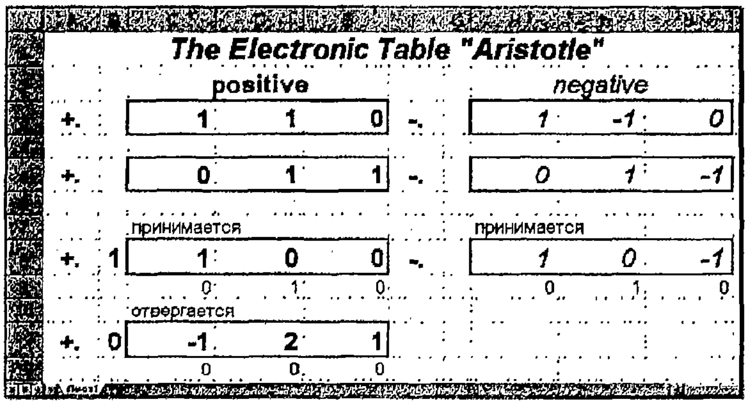
«There are no Centaurs (x) with wings» = E x y = -(1, 1, 0)

«There are no Centaurus-Pegasus (xz)» = Ex z = -(1, 0, 1)

The conclusion can be obtain by the first Carroll's figure: out of two Chimeras with excluded terms of different signs follows Chimera, in which the left terms remain their signs.

The proposed algorithm permitted to realise the solution of syllogisms in a form of electronic tables *Excel* [6]. This was realised by the author in an electronic table *Aristotle.xis:*

The components of *positive vector* in an electronic table *Aristotle.xis are* computing as the remainders of: C8 = C3 - H5, D8 = D3 - 15, E8 = E3 - J5 and parallel the control figures are found: C9 = IF(ABS(C3 + H5) = 2; 1; 0), D9 = IF(ABS(D3 + 15) = 2; 1; 0), E9 = IF(ABS(E3 + J5) = 2; 1; 0), and a sum is calculated B8 =SUMM(C9 : E9), according to which a vector is accepted or rejected: C7 = IF(B8 = 1, «accepted»; «rejected»). Similarly, the components of *other positive vector* is computed: C11 = C5 - H3, D11 = D5 - 13, E11 = E5 - J3 and control figures



are found: C12 = IF(ABS(C5 + H3) = 2; 1; 0), D12 = IF(ABS(D5 + 13) = 2; 1;0), E12= IF(ABS(E5 + J3) = 2; 1; 0) and the sum is amounted B11 = SUMM(C12 : E12), according which the vector is accepted or rejected: C10 = IF(B11 = 1, "accepted"; "rejected"). The components *of negative vector* are computing as sum signs: H8 = SIGN(H3 + H5), I8 = SIGN(I3 + I5), J8 = SIGN(J3 + J5) and the appropriate control figures are found: H9 = IF(ABS(H3 - H5) = 2; 1; 0), I9 = IF(ABS(I3 - I5) = 2; 1; 0), J9 = IF(ABS(J3 - J5) = 2; 1; 0), and the sum is computing G8 = SUMM(H9:J9), according which the vector is accepted or rejected: H7 = IF(G8 =1, "accepted"; "rejected"). The change of component values of the first couple of positive and negative vectors in cells C3, D3, E3 and H3, I3, J3 and also of the second couple of positive and negative vectors in cells C5, D5, E5 and H5, I5, J5 of electronic table leads to its automatic recounting. *Computing results are being read in sells:* C8, D8, E8 (for a positive vector of conclusion) and H8, I8, J8 (for a negative vector of conclusion) and also C11, D11, E11 (for a second positive vector of conclusion).

The method was reported at 8-th International Logic Congress [7] and at 1-st International Conference on fundamentals of artificial Intelligence in Paris in 1991 [8].

Many-aspects method is an analytical method, which is applicable for logic mass data of *any dimension*. It would rather instructive to consider poly-syllogism from Carroll's *«Symbolic Logic»:*

«1. No one out of met in the sea things, being remained unnoticed, are not the water-nymph. 2. The things, met in the sea, and which are recorder in a log book, are worth to be remembered. 3. Along with my travels I saw nothing to be remembered. 4. The things met and noticed in the sea are registered in a log book".

Let as put down it through five-dimensions vectors of a form $(x_1, x_2, x_3, x_4, x_5) = (x, y, z, u, v)$:

No one y *is not* u = +(0, 0, 0, 0, 0) - (0, 1, 0, -1, 0)

All x essence v = +(1, 0, 0, 0, 1) - (1, 0, 0, 0, -1)

No one z is not v = +(0, 0, 0, 0, 0) - (0, 0, 1 ,0, 1)

All u essence x = + (1, 0, 0, 1, 0) - (-1, 0, 0, 1, 0)

Not one y is *not* x = + (0, 0, 0, 0; 0) - (0, 1, 1, 0, 0)

The conclusion: «I never saw a water-nymph». By means of Carroll's diagrams the resolution of this poly-syllogisms can not be obtained, because the increase of dimension makes the geometrical method unworthy. The traditional ways of solution are applicable exclusively to syllogisms with tree terms. They are grounded on modus classification for 4 figures and are required the memory of mnemonic Latin words.

To make it easy afterwards to get the solution of *any* syllogisms it is better to master the analytical method first.

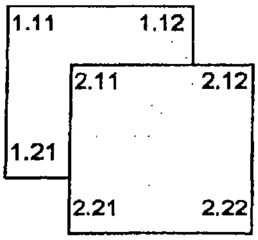
In dichotomous classification 1 shall value *the first outlet* («need»), 2 - *the second outlet* («tail»). Therewith 0 values *«do not known»* ("nead and tail»), but not the third outlet. The tops of logic cube: 2.11 and 2.12 are linked by horizontal edge 2.10. The idempotent adding is produced modulo 3. Making this component-by-component for *x*: 2 + 2 = 2, for *y*: 1 + 1 = 1 and for *z*: 1 + 2 = 0, we obtain 2.11 + 2.12 = 2.10. Note, that 2 = -1 (*modulo* 3).

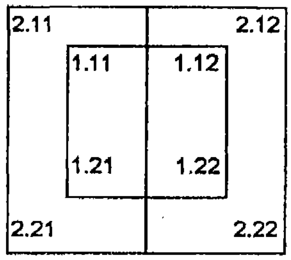
While writing down the address code, we shall miss parenthesis and comas, and the first aspect we separate by point. The vector (*x, y, z*) denotes a set of aspects: [1] *of sheet*, [1] *of line*, [1] *of column*. As an example, we input a classification, where for universe 0.00 the following values are taken:

> *«I'd like to charge this with your debt*
> *The logic courses to attend...*
> *In brain, just like on a fabric*
> *There are the threads and crossing-links.*
> *The premises, of not this shape,*
> *Will threaten shuttles implicate.»*
> *Goethe, «Faust» (trans. B. Pasternac)*

1.00 concrete values	2.00 abstract values
1.10 concrete algebraic values 1.11 *concrete algebraic scalars* 1.12 *concrete algebraic vectors*	2.10 abstract algebraic values 2.11 *abstract algebraic scalars* 2.12 *abstract algebraic vectors*
1.20 concrete logic values 1.21 *concrete logic scalars* 1.22 *concrete logic vectors*	2.20 abstract logic values 2.21 *abstract logic scalars* 2.22 *abstract logic vectors*

The concrete values 1.00 are represented by the first sheet of card-file from the left, and from the right - by square of diagram of Carroll. The operations are fulfil component-by-component. For logic vectors the indemponent addicting is produced modulo 3. For example, 1.11 + 1.12 = 1.10, that means: *concrete algebraic scalars + concrete algebraic vectors = concrete algebraic values.* Similarly, 1.21 + 1.22 = 1.20, that means: *concrete logic scalars + concrete logic vectors = concrete logic values.* Non-concrete (abstract) values 2.00 are presented by the second sheet of a card-file from





the left, and by the external square of Carroll's diagram - from the right.

The most not-simple things are appeared to be the exactly «simple» meanings («not simple simplicity»). Not in vain one says: «Just don't put the simple questions». Even *«simple»* numbers are abstract (non-concrete) numbers, which are obtained through abstracting from object's names. In real life a *simple* number is zero only (not without reason it was not known in Ancient Greece). For example, one can't say, that a fisherman caught 0 crucial (but from where it is known that not pieces?). This is a situation of uncertainty, which is used to be denoted in logic by zero.

To think abstractly-means to eliminate all object's features, which are considered unessential for define examination. A classical example may be taken from an article of Hegel «Who thinks abstractly?» with its market woman with rotten eggs. She thinks abstractly, because she is seeking only for negative features of buyer woman to offend her.

The solution of practical tasks requires to pass from non-concrete (abstract) numbers to arithmetical operations with concrete numbers. The difficulties along with introducing the vectors at the end of the last century on Maxwell's electromagnetic theory acceptance can, in many ways, be explained by a necessity to overcome the psychological barrier. It has been known, now vector writing down had been rejecting, and we are obliged to Maxwell and Heavyside for its introduction in subject, and the latter lovely called his predecessor as *«aven-sent Maxwell»*. Heavyside did afraid of descriptive explanations: «Mathematician, willing to develop the vector approach, should better learn, how a laundry-women *put together the* shirts - separately, the sheets - separately».

The logic tasks, from the standpoint of concrete approach, lead to a necessity of named vectors use. The named logic variables appeared in index method of Carroll They go back to Bool's constituent, which can be considered as a prototype of logic vector. The *algebra of Boole* (developed by Boole himself) is often confused with Boolean algebra, that was constructed by his successors - Jevanson and Shreder, which lost the meaning of constituent many other things. In paper [8] the index method of Carroll and algebra of Boole are examined. Note, that coefficients for Boole's constituent had taken the four values. Therefore, Boole is a precursor of multi-valued logic.

The computer catalogues *Windows* are composed in form of trees, that are extremely awkward. For instance, the restructuring of catalogue in a way of ideology of *Windows 95* required the substitution of catalogue C:\windows\system\docum\cross.doc for catalogue D:\work\doc\cross.doc. The more convenient way of classification are the dialogue windows, which in *WinWord6* gained a new form - a set of cards in a card-file [9]. The version *Excel 5.0* also uses three-dimension dialogues in a form of boxes with card-imbedding [10].

The tables of content in a form of double-letters and triple-letters diagrams of Carroll are descriptive and do not require any restructuring on priorities replacement, but they are ineligible for many-dimensional case. *The methods of analytical classification* by means of many-subjects logic vectors allows to use adding and subtraction of vectors, while it is impossible to do this with a pattern in a form of asterisk sign*, which is used as a symbol of uncertainty for computer classification [11].

The use of address codes allows to obtain a many-dimensional system of classification. There with the *algebra of logic vectors* permits to have a simple instrument for operation with catalogues, in which it is easy to realise the combinations according to any selected feature. Therefore it would be better to take advantage of logic vectors for computer catalogues.

The transition from one-dimensional representation allows to reveal the latent periodicity. In similar approach in theory of numbers one can literally *see a* number of known theorems and obtain the new results [12]. The well-known example of this kind is a table-calendar, in which a seven days-rhythm is visualised. The horizontals in the table-calendar form the days of current week, and the week's Sundays rhythm sets forth along a vertical column.

Unlike the one-dimension physical time *(time) the grammatical time (tense)* is a single two-dimensional mass data of past, present and future, in which the tenses are built up in one above other, as in a stack, but are not stretched along one line. The generalisation of concept of two-dimensional time leads to a method, revealing the characteristic cycles [13].

On linear reading the network of mass data becomes realised into a thread of time - the "ganglions" of structural network collapse (because of break of natural vertical ties). Here we have an analogy with a transmission of image by telefax, where a vertical is unrolling in rhythmical signal interchange, while on receiving of phototelegramm the dotted line of rhythm again roll up into a vertical, perpendicular to the lines of raster. The method of analytical classification *(project «CrossWord »)* is the firs step on a path of overcoming the *one-dimensional* thinking. The term of *CrossWord* sounds as an appeal to table-form of representation.

The conception of many-subjects approach in logic has originated 20 years ago, when the author had proposed a *matrix model of* paradox [14], but only 10 years afterward the *logic vectors* of Carroll has been gained in discern. *The many-aspects approach* became a methodological basis of logic analysis of complex logic situations. The problem of paradoxes testifies, that the *logic many-dimensionality* is hard to realise.

For majority of logic paradoxes it is sufficient to use the two-dimensional logic vectors arises, for example, in paradox of voting. Carroll wrote several articles about elections in Oxford University and a paradox of voting («effect of Kondorse»). He formulated the essence of paradox like this: «A majority can be "cyclic", that is, it can be a majority *A* over *B*, *B* over C and C over *A» (paradox of non-transitivity)*. The preference patterns can be written (on aspects *A, B, C)* by means of logic vector: $V_A = (+1, 0, -1)$, $V_B = (-1, +1, 0)$, $V_C = (0, -1, +1)$ for *A*, *B* and *C*, accordingly. The component can accept three values: +1, -1 and 0 for voting results: *«pro»*, *«con»*, *«abstain»*.

An example of paradoxical object exists in a *double dictionary* including Russian-English and English-Russian dictionaries, placed under one cover. If it is Russian, then it is English, but if it is English, then it is Russian. In article [15] the matrix models of paradoxes are given, which are based on mathematical theory of representations. The paradox is generated by an attempt to reduce a complex logic situation, described by the matrix, to a unit element. That is why the new representations are accepted firstly as «delirium» (paradox), and then as an «evidence» (the resolution of paradox). Ekkerman in «Talks with Goethe» cites the expression «square circle» as a reference of contradictive meaning. But once you pull apart the square and the circle towards different projections, the paradox the resolved. And we are surprised by dullness of two-dimensionists, described in «Flatland» of E. Ebbott, which can not imagine a «square circle» (*cylinder*).

However, one ought to warn about a rode mistake of seining the reason in geometrical evidence. In fact, although one can't image visually a «cubic sphere», but the paradox is resolved through pulling apart the cube and the sphere into different projections. Note, that a «cubic cube» is a four-dimensional cube, having cubes in different projections (it even is succeeded to be sketched). Similar to this the expression "*guilty without guilt*" is paradoxical, but the paradox can be resolved when *«not guilty»* (de-facto) and *«guilty»* (de-jure) are pulled apart toward the different logic projections (aspects). The repression ***«sparkle of wit»;*** meaning a superposition of incompatible things, alludes the physical effect of «stereo-glitter». The same is for idiomatic expressions: ***«how - no how», «was - never was», «visible - invisible», «willing - unwilling», «self - not himself».***

Jeaque de Leuse wrote: « We cannot save ourselves from paradoxes implying that the sense is always taken into account in two senses-directions simultaneously [16]. All modem paradoxes are in close relation with the «Liar» ancient paradox. Even those school children who never heard about logic know the above paradox by heart. Its presentation during the lessons provokes the interest aimed at logic learning with the purpose of mastering of how to think correctly. The Crete philosopher Epimenid (sixth century A.D.) is said to state «all Crete inhabitants are liars». Let us assume that the above Epimenid statement is a truth. Then, according to its sense and the fact that Epimenid himself is a Crete inhabitant, this statement is a lie.

The identification of truth and its estimation brings to a paradox. In reality «estimated as falsehood » *(rejected)* can be both a truth, and falsehood. If the evaluation is authentic, the it is a ***rejected falsehood,*** but if the evaluation is not authentic, then is ***rejected truth.*** We than have a table:

	truth	evaluation	authenticity
Option 1	falsehood	rejected	authentic
Option 2	truth	rejected	non-authentic

The evaluations are the labels, attaching to truths being authentic (on their coincidence) or non-authentic (on their not coincidence). V. Quine suggested to distinguish a falsehood and quotation-marked «falsehood» [16]. The logic vector $\{x, y\}$ has two aspects; x – ***truth and*** y - ***evaluation.*** The selection of various aspects allows to show, that in paradox of «Liar» there are two different situations, since a quotation-marked «falsehood» (*rejected*) can be reality both a truth and a falsehood:

«F» = T (rejected truth),

«F» = F (rejected falsehood).

Here the quotation-marked evaluations are the labels, attached to truth.

A multi-level cognition is a typical human feature. The parallel levels are connected between each other by a metaphor, without which there would be no glossary of «invisible worlds» (internal human existence). If a «soul depth» would be accepted by our sight as, for example, clearly as red colour, we, no doubt, would use for its notation the direct and only to it belonging name. Nonradomly, one of the important obstacle on the way of creation of artificial intelligence is a problem of assimilation of metaphorical thinking by a computer.

«PROOVER» FOR NATURAL CLASSIC CALCULUS OF STATEMENT

A.E. Bolotov, V.A. Bocharov,
A.E. Gorchakov (Russia)

The idea of searching algorithm for natural calculus of classic logic statement are represented hereto. The peculiarity of this algorithm, realized in language C for IBM PC, lies in the fact, that the authors were succeeded to formalize heuristics, which are used along with natural reasoning. This allow to find an effective procedure for realizing the subordination deductions. The specific peculiarity of proover in the fact, that it allows not only simple checking of general validity (provability) of classic logic propositions, but to structure a deduction itself in an ordinary traditional sense of this word.

The system, laid in a basis for this, composes a natural calculus of propositions, presented in a textbook «The fundaments of logic» of V. Bocharov and V. Markin. An idea of algorithm is that it forms two sequences of formulas according to some prescribed deducibility. The first sequence comprises the formulas of deduction, the second - formulas-aims. Initially these two sequences are formed as follows:

- it is necessary to realize a deduction of some formula W from a set of premises W_1, ..., W_k, then the formulas W_1, ..., W_k are the original list of deduction formulas, and the formula W is considered as a main aim, and if this aim is achieved, the deduction is held to be completed;
- it is necessary to realize a deduction W from empty set of premises, the list of deduction is empty, and formula W is placed in the list of aims. Naturally, this formula is the main aim.

An algorithm means, that the following procedures are realized according to deduction formulas:

1. The sequence of formulas deduction is formed.
2. The new aims, which are the subaims of the main aim, is formed.
3. The test of attainability of the last aim in the aim list is accomplished.
4. From the other side, the following procedures are performed according to ***formulas-aims:***
5. The subaims, placed in sequences of aims, are formed.
6. The new supplementary premises, placed under next number into a deduction, are choused.
7. The necessity of automatic utilization of appropriate rules in a deduction, is signalized.

The Procedure 1 consists of one or two exclusions of logic connectives. If such formulas are discovered, then the deduction is added by the result of this rule application.

The Procedure 2. This Procedure is performed in the case when all possible rules, indicated in Procedure 1, were applied, and the last aim of sequence is «F» (contradiction), but there with this aim is not achieved (see the Procedure 3). What precise aims are introduced, are determined by the forms of deduction formulas contained:

2.1. If a deduction includes an implicate formula of the form $W_1 \supset \Box W_k$, so W_1 is taken as a subaim.

2.2. If a deduction includes a disjunctive formula of the form $W_1 \vee W_k$, so $\neg W_1$ is taken as a subaim.

2.3. If a deduction contains includes a formula of the form $\neg(W_1 \vee W_k)$, so $W_1 \vee W_k$ is taken as a subaim.

2.4. If a formula $\neg$ (W_1 & W_k) is occurred in a deduction, so W_1 & W_k is taken as a subaim.

2.5. If a formula $\neg$ ($W_1 \supset \Box W_k$) is occurred in a deduction, so $W_1 \supset \Box W_k$ is taken as a subaim.

No other formulas serve as a source of new aims, since the Procedure 1 is applied to them automatically.

Procedure 3. If the last aim is held to be some formula, so it is believed to be achievable simply through the fact of existence of graphically equal to it formula. If, however, the last aim if F, so it is considered as achieved, it a deduction contains the formulas of the form A and $\neg$A. The achieved aim is excluded from aims list, and the next aim become the previous one.

The Procedures 4 and 5 we describe together, because in some cases they are used simultaneously. The present Procedures are coming into use in the case, when the Procedure 1 is applied already, the aim is some formula, and it is reached. In this case depending on a form of the next (last) aim we are acting as follows.

4-5.1. If the aim is a formula of the form $W_1 \supset W_j$, so W_j becomes a new aim, and W_1 is taken as a premise.

4-5.2. If a formula of the form W_1 & W_k is the aim, so W_1 and W_k becomes a new aims. Therewith it is obligatory, at first, to achieve the aim W_1, and only after its achievement, to reach the aim W_k.

4-5.3. If the aim is a formula of the form $W_1 \vee W_k$, so W_1 or W_k become a subaim. If none of these subaims is not achieved, then a formula $\neg$ ($W_1 \vee W_k$) is taken as a new premise, and F becomes a new subaim, while the aims W_1 and W_k are being taken away.

4-5.4. If a prepositional variable p is an aim, then its denial $-\neg$ p is a new premise, and F becomes an aim.

4-5.5. If a formula of the form $\neg$ A, where A is an arbitrary formula, is the aim, the formula A is taken as a new premise, and F becomes a new aim.

The Procedure 6. Each case of some aim's achievement signalized about a necessity to fulfil some stages of deduction. In most cases it is required to perform in automatic regime the appropriate rule of introducing of logic connectives. In more details it is described as follows:

6.1. If a formula of the form W_1 & W_k is a direct superaim, and the last in a list of aims are the formulas W_1 and W_k, being the direct subaims of this formula, and if formula W_1 is achieved, then it serves as signal about the necessity to pass for achieving the aim W_k. In this case, when the W_k is achieved, that is, the both subaims are reached, then it serves as a signal to realize in deduction the rule «$\&_B$» and to obtain by this, in consequence of deduction, the formula W_1 & W_k. Note, that this means the achievement of the aim W_1 & W_k.

6.2. If a formula of the form $W_1 \vee W_k$ is a direct superaim, and the last in a list of aims are the formulas W_1, W_k, and if one (any) of these aims is reached, then this is a signal to realize in deduction the rule «$\vee_B$», that is, to include in consequence of deduction the formulas $W_1 \vee W_k$. By this the $W_1 \vee W_k$ is reached too.

6.3. If a formula of the form $W_1 \supset \Box W_k$ is a direct superaim, and the last in a list of aims is a formulas W_k as it direct subaim, and it is reached, then it serves as a signal to realize the rule «$\supset_B$», that is, to include in consequence of deduction the formulas $W_1 \supset \Box W_k$. By this the aim $W_1 \supset \Box W_k$ is achieved.

6.4. If a formula W is a direct superaim, where W is a formula of arbitrary form, and F is the last direct its subaim, and if the aim F is reached, then it serves as a signal of application of the rule «$\neg_B$» in a deduction. This either leads to obtaining of formula W in deduction at once, of it is obtained after application of a rule «$\neg_{and}$». In any of these cases the aim W is reached.

The proof of the Pierse law, carried out by a computer in automatic regime on the basis of described algorithm, is given below.

The present theorem is taken from a set of examples, by means of which the present software was adjusted.

It is required to be proved $((p \supset q) \supset p) \supset p$

0	$(p \supset q) \supset p$,	Premise
1	$\sim p$,	premise
2	p,	premise
3	$\sim q$,	premise
4	$\sim\sim q$,	~ in out of 1,2
5	q,	~ and, from 4
6	$p \supset q$,	⊃ in 2 to 5
7	p, ⊃and,	from 0, 6
8	$\sim\sim p$,	~in out of 1, 7
9	p,	~ and, from 8
10	$((p \supset q) \supset p) \supset p$	⊃in 0 to 9

The program, realizing the described algorithm, was written in a high level language «C» for computers of a type IBM PC AT. The program occupies 140 Kbytes on a disk, an operation time for tested theorems proof does not exceed 4 sec for a personal computer on the basis of a processor INTEL-386-DX with a rate of 40 MHz. The program has a user's interface and can read previously prepared formulas from a file. The testing was carried out for a lot of formulas, selected out of the textbooks on mathematical logic and, in particular, from the A. Church «The introduction to mathematical logic» This set (of about one hundred theorems of classical logic) is a representative enough, and allows to consider the proposed algorithm of searching the deduction for natural calculus of statements as an efficient procedure of subordination deduction realizing.

The elaborated by the author algorithm of structuring of deduction and proof for propositions of classical logic and its computer realization if of great importance for educational objectives.

For the first place, right now on a basis of presented algorithm (after its detailed presentation) there is a possibility to train the students with procedures of deduction and proof-procedures, which are well known to everybody, who taught logic, and are rather difficult for understanding. The experience of teaching the logic on philosophical faculty of Moscow State University shows, that students are quickly mastering this algorithm, and therefore the procedures of deduction search and proof in classical logic become not difficult for them.

For the second place, on the basis of computer realization of the considered algorithm it is assumed to develop in a nearest future a computer program, which would independently train the student with procedures of deductive inference, which would control this process, would provide the prompts at required cases, and also would carry out testing of students on their mastering the subject and would make an estimate of students. In this case the process of training of deductive procedures would be automized completely.

For the third place, the present computer program should be used by logic-specialists as a slight support in these studies. In those or other cases the investigator can realize by means of a computer the required with it deduction, and so obtained the results to transfer into the text of his article or book.

The paper is carried out under Russian Humanitarian Scientific Foundation Support; Grant No 96-03-04666.

THE EXPERIENCE OF LOGIC TEACHING BY MEANS OF A COMPUTER PROGRAM «DEDUCTIO»

I.A. Gerasimova (Russia)

The computer programme *DEDUCTIO* (the authors - A. Srnrnov, A. Novodvorsky, edited by V. Smirnov) was used in the course "Foundation of Logic", which was read to students of philosophical faculty under Humanitarian College in the Institute of Philosophy of Russian Academy of Science. This programme contains a wide choice of logical systems, however, according to training themes only two of them were attracted: axiomatic system for logic of statement and natural deduction for logic of propositions and logic of predicates.

The key objective of the course "Foundation of Logic" is a mastering of basic concepts and methods of modem logic inside its philosophical orientations. It is supposed, that students, having mastered the concept of logical form, the basic formalized languages, with most important modes of proof, will be able to approach to the main, from the informative point of view, part of this course: the acquaintance with ideas of logical semantic, the theory of logical succession, with modal, temporary and other nonclassical logics, interesting either for logic or other philosophical disciplines (ontology, epistemology, methodology of science, philosophy of language). However, while grammatical forms and mathematical relations are studied in secondary school, logical form and logical relations become familiar for the first time only in higher school. Even the elements of classical logic require a lot of time for successful understanding - nearly the whole two-terms course.

Therefore, the wide use of computer training programmes spares time, for sure, and causes the conditions for realization of key creative ideas of a teachers. The following objectives, which were put ahead along with logic training by means of program *DEDUCTIO*, can be singled out:

- to learn the variants of proof by means of axiomatic method;
- to master the technique of natural deduction in logic of propositions and logic of predicates;
- to learn making differences between proof and proof search;
- to be able to distinguish the analytical and synthetic methods of proof search;
- to master the basic ways of direct and indirect proofs;
- to master the most important principles of classical logic not by mechanical learning, but through a search of proof by means of a computer. The students should meet the following demands:
- for the first place, to be able to form a proof both with a computer and without it;
- for the second place, to be able to transform the procedure of proof searching into the resulting proof.

The collection of rules of natural deduction (rules of introduction and extraction of logical symbols), accepted by a computer program, differs slightly from standard sets of axioms of natural calculus. These differences are caused by a necessity of correlation of rules of natural deduction and the applied procedures (rules) of proof searching. At the same time, the suggested systems of natural deduction are deductively equivalent to classical calculus of propositions and predicates.

The rules of searching can be partitioned on analytical and synthetic. The analytic rules lead a task solution to a solution of sub-task - to building up the auxiliary sub-deductions. The synthetic rules allows to solve the given task without reducing it to sub-tasks.

The analysis of results concerning to application of searching rules are presented automatically, while a student fulfills the choice of a rule itself. In the event of a mistake a computer sends a message: "This rule is not applicable". After the complexion of deduction searching process it is summarized: «The deduction is completed». The additional commands remove the extra steps, while renumbering takes place. The analysis of a ready deduction is formulated along with indexation of application of natural system rule.

To the end of the 1 term practically all the students had mastered the skills of operation with computer program *DEDUCTIO*, and had been able to prove the basic theorems of classic logic propositions. In reality the students, which studied the informatics in a secondary school, required much less time for mastering the proofs and deductions with a computer. At the same time some students, being able to operate with a computer, could not show this without a computer. This testifies that understanding the material occurred mechanically, not consciously. However, basically, the group solved its problems.

The study of logical science requires, surely, the permanent solving of problems, therefore, the development of computer systems, like the program *DEDUCTIO*, promotes the success in training process significantly.

QUASIMATRIXES AND SEMANTICS OF BOUNDED DESCRIPTION SETS OF STATES AS THE MEANS OF COMPUTERIZATION OF MODAL REASONING

Yu. V. Ivlev (Russia)

In the last few years a series of electronic textbooks on define subjects of the general logic course, as well as on classical symbolic logic, were created. The problem of preparation of manuals of this type faces the modal logic, since the reasoning, being described in this logic, are realized both in humanitarian and natural sciences, and the training of students in modal logic without using the technical means does not always reach the prescribed goal.

The algorithmic methods of analysis are required for modeling of modal reasonings by means of a computer instrument. Presented here are the two of such methods.

Quasimatrixes. As it is known, the matrix is the set $<K,M,\varphi^1,...,\varphi^n>$, where K– set of matrix elements; M - set of separated elements, $\varphi^1,...,\varphi^n$ — a function, having a range of possible values and arguments in a set of K. Quasimatrix is the set $<K,M,\delta^1,...,\delta^n>$, where K and M – the same as above, and $\delta^1,...,\delta^n$ - quasifunctions. Quasifunction is a congruence, by virtue of which some object (unknown) out of define subset correlates with some object (unknown) out of define subset of the same or another set.

On example of quasimatrix: $<\{t, f\}, \{t\}, \delta^1, \delta^2>$. Here t and f are values of truthness «truth» and «false» accordingly, and δ^1, δ^2 are the quasifunctions, determined by tables: $\delta^1 A$, $\delta^2 A$.

t/f	t	t	t
f	t	t/f	f

The notation *t/f* is regarded as an uncertainty, is read *«whether truth or false»* and does not mean the independent value. By means of quasifunctions the δ^1 and δ^2 are interpreted as modal operators □ (necessary) and ◊ (probably), accordingly, that allow to disprove the statement of Ya. Lukasevich about impossibility to identify them in terms of truth and false.

Let us consider the formulas: $\Box A \supset A$ и $A \supset \Diamond A$. It is evident, that if A has the value t, then the second of those formulas has the value t. Let us treat the remained cases: $\Box A \supset A$, $A \supset \Diamond A$.

t/f tt tf t/f f

Since an uncertainty t/f does not convey the independent value, one should treat subcases, taken two at a time:

$\Box A \supset A$ и $A \supset \Diamond A$

1. tttt fttf

2. fttt ftff

The formulas are truth logically. The quasimatrix, presented as an example, is adequate to calculus S_{min}, the schemes of axioms of which are the given above formulas, and the single rule for deduction in modus ponens.

An uncertainty t/f arises on assigning some values to formula $\Box$ A with value t for formula A. Therewith we argue in a following manner: the situation, described by statement A, takes place on necessity or occasionally. In first case we assign to indicated formula the value t, and in the second case - f. In fact, we initiate from the fact, that a statement, taking the value t, can be estimated, additionally, as necessary (ontologically) or occasionally (ontologically). The last values we designate by letters *n* and *c*, accordingly. The composed values «A necessary truth», «a random truth», «necessary false» («false and impossible»), «a random false» we designed as: t^n, t^c, f^i, f^c. accordingly. Let us bring one of the system of four-valued quasimatrix logic - S_a^+. The distinguished values are t^n and t^c, the letters t and f are used as abbreviations of expressions t^n / t^c and f^i / f^c accordingly.

A	¬A	□A	◊A
t^n	f^i	t	t
t^c	f^c	f	t
f^i	t^n	f	f
f^c	t^c	f	t

$\supset$	t^n	t^c	f^i	f^c
t^n	t^n	t^c	f^i	f^c
t^c	t^n	t	f^c	f^c
f^i	t^n	t^n	t^n	t^n
f^c	t^n	t^c	t^c	t

The calculus S_a^+.

1. The schemes of axioms of classical calculus of statements.

2. The supplementary schemes of axioms: $\Box A \supset A$; $\neg \Box \neg A \supset \Diamond A$; $\Diamond A \supset \neg \Box \neg A$; $\neg \Diamond A \supset \Box (A \supset B)$; $\Box B \supset \Box (A \supset B)$; $\Box (A \supset B) \supset (\Box A \supset \Box B)$; $\Box (A \supset B) \supset (\Diamond A \supset \Diamond B)$; $\Diamond (A \supset B) \supset (\Box A \supset \Diamond B)$; $\Diamond B \supset \Diamond (A \supset B)$; $\Diamond \neg A \supset \Diamond (A \supset B)$.

The rules of deduction are *modus ponens* and the rule of substitution of arbitrary quantity of entering of formula ¬¬ A on A and vice versa.

Semantics of bounded sets for the description of states. In modern logic a principle, according to which the value of complex proposition is determined by constituted in simple statements (elementary or atomic), is widely used. In classical logic these values are «truth» (t) and «false» (f). In a logic, describing the logic modality «necessary» (□) and «probable» (◊), these values are «a logic truth", "a logic false" and "a logic non-determination". The last values are designed as : *N, I, C*.

Let a formula $\Box (p \supset q) \supset (\Box p \supset \Box q)$ is given suppose, that the variables p and q has the values of *N* and *C*, accordingly, that is, the first of them is interpreted as a logically truth proposition, and the second - as logically non-determinated one. The whole number of state descriptions for mentioned formula equals to four: $\alpha 1 = (p \& q)$; $\alpha 2 = (p \& \neg q)$; $\alpha 3 = (\neg p \& q)$; $\alpha 4 = (\neg p \& \neg q)$. Since the elementary propositions are interpreted trough above mentioned way, that is, *p* can not be false, then α3 and α4 are eliminated out of a set of possible state descriptions. The obtained set of state description $\{\alpha 1, \alpha 2\}$ is called a bounded set of state description. A set of possible state descriptions for formula we designate by letter *W*, and the bounded set of descriptions as (OMOC) – *W'*. If the two or more elementary propositions are interpreted as logically non-determined, then the conjunction of these propositions (the conjunction of denial of these propositions), in turn, is interpreted as a logically possible proposition or as a logically false proposition. That is, the subsets, named subOMOC, can be formed for OMOC. SubOMOC is denoted by letter *W"*. All possible sublets of original set *W* of state description are formed as a result of presented interpretation of elementary propositions. The value in state descriptions, incoming to subOMOC, as assigned to formulas. The elementary proposition is truth in state description, if and only, if it is involved in this state description without the sign of denial. The formula A&B is truth in state description, if and only, in this state description the formulas A and B are truth, and so on for other nonmodal logical terms. The formula □ A is truth in state description of subOMOC, if and only, if the formula A is truth in each state description of this subOMOC.

The formula ◊ A is truth in state description of subOMOC, if and only, if the formula A is truth in some state description of this subOMOC. The formula is logically feasible, if and only, if it is truth in some state description of some subOMOC. The formula is generally valid, if and only, if it A is truth in each state description of each subOMOC.

Of generally valid are these and only those formulas, which are probable is calculus S5 of Lewis. Now the essence of model structures of relational semantics is apparent for this calculus. The model structure is one of the interpretation of prepositional variables, entering in formula (in formulas), by means of above mentioned values, and, also, the interpretation is conjunctive of prepositional variables (in front of some of them may be a sign of denial), interpreted as logically non-determined propositions, as a logically possible or logically impossible statement.

Let now the subOMOS is a set **< *OΓ'*, *W"*>**, where ***OΓ'*** - the indicated interpretation of prepositional variables and described above conjunction, denoted by means of formulas as follows: if a value ***N*** is assigned to prepositional variables ***a***, then the formula $\neg\Diamond\neg a \in O\Gamma'$, if - ***I***, so - $\neg\Diamond a \in O\Gamma'$, if ***C***, then - $\Diamond a \;\&\; \Diamond\neg a \in O\Gamma'$, if indicated above conjunction was interpreted as possible, then in ***OΓ'*** this conjunction is included with a proceeding operator of possibility, and if as impossible - then with prefix ¬◊. After this the following lemma can be formulated, and its proof is necessary for proovement of methatheorem about semantic completeness.

Lemma. Let D is a formula; **<*OΓ'*, *W"*>** is a subOMOC; $a_1,\dots,a_n$ — all various variables, involving in ***D***, $b_1^\alpha,\dots,b_n^\alpha$ - truth values of these variables in state description α such, that $\alpha \in W'$, A_i^α is α_i, if b_i^α is t, and also $\neg\alpha_i$, if b_i^α is f. Let D^α is ***D*** or $\neg D$ depending on whether ***D*** accepts a value t or f in *a*. Then $O\Gamma' \cup \{A_1^\alpha,\dots,A_n^\alpha\} \vdash D^\alpha$ (we write further as $O\Gamma', A_1^\alpha,\dots,A_n^\alpha \vdash D^\alpha$).

The lemma is proved by reciprocal induction, according the number of logical terms entering in formula ***D***. A set ***< OГ', W", D>*** is the subOMOC in semantics of predicated, where ***W"*** - a set of state descriptions (regarded not as conjunctions, but as sets), the admissible interpretations ***OГ'***; ***OГ'*** - the complete interpretation of atomic prepositions, that is, statements and their (finite) conjunctions; ***D*** - not empty area. The atomic formula in state description without independed variables accepts the value t or f in ordinary way. The values in state descriptions are assigned in ordinary manner to formulas of the form $\neg A$, $A \& B$, $A \vee B$, $A \supset B$, $\forall \sigma A(\sigma)$ and so on.

The formula $\Box$ A takes the value t in state description $\alpha(\alpha \in W'')$ on values distribution over independent variables S, if and only if for this description the formula A accept the value t in each state description from ***W''***.

The predicative extension of predicative modal logic. The adequacy to this calculus of semantically preassigned system is proved.

Thus, the semantics is obtained, reveally the essence of logic modalities, that gives grounds to argue about developing the theory of these modalities.

A COURSE OF DEDUCTIVE LOGICS IN A SUPPORT OF THE PROGRAMME FOR INTERACTIVE SEARCH FOR PROOF

V.I. Markin, A.E. Novodvorsky, A.V. Smirnov (Russia)

In 1991 A.V. Smirnov, A.A. Fokin and A.E. Novodvorsky have developed the first version of the *DEDUCTIO* programme of interactive search for proof. The programme permitted describing at the level of data some logical calculi and supported working with them. The program was demonstrated at a seminar of the Logical Center, Institute of Philosophy, Russian Academy of Sciences, and subsequently in the Stanford University. Prof. V.A. Smirnov proposed using *DEDUCTIO* for the teaching of logics and initiated development of a course of logics integrated with a computer program. In the course of that work V.A. Smirnov and V.I. Markin prepared and read study courses at the Faculty of Philosophy, Moscow University (1992 - 1996), in the Salzburg University (1993) and in the Humanitarian College of the Institute of Philosophy, Russian Academy of Sciences (1995 - 1996). A.V. Smirnov and A.E. Novodvorsky authored a new version of the *DEDUCTION* programme, taking into account the peculiarities of the study process.

The course of deductive logics was based on a theoretical-proof approach. The focus was on the basic notions of symbolic logics as deduction and proof, the methods for search of deduction in different logic calculi.

The course is permeated by the concept that the meaning of logical constants can be set not with syntactic rules of operations with certain formulas rather than conventional semantic definitions (e.g., truth tables). In fact, in natural calculi, the above role is played by the rules of entry and elimination of prepositional connectives and quantors. For instance the meaning of the conjunction (&) can be defined by the following deduction rules:

$$\frac{A, B}{A \& B}, \quad \frac{A \& B}{A}, \quad \frac{A \& B}{B}.$$

There are two definite questions: (1) what is a correct logical deduction (proof) and (2) how to search for the needed deduction effectively. The focus is on the consideration of the second problem, which is of great practical importance. To ensure the maximal illustrativeness and "naturalness" of consideration, the problem for the search for deduction is initially investigated with special reference to natural logical calculi—the classic prepositional calculus, the classic predicate calculus, predicate calculus with equality.

The methods and heuristic methods for obtaining deductions are stated as a some system of precise rules, i.e., *the rules for the search for deduction*. These should be distinguished from the rules of deduction of the logic system itself,, which rigidly define the relationship between the formulas in the resultant deduction. As to the search rules, they set admissible modifications of the deduction search tree.

There are two varieties of search rules: *analytical* and *synthetic*.

The synthetic rules permit adding some new formulas to the current deduction in the course of solving of the search problem. For instance, the synthetic rule of implication elimination (c) in the presence in the deduction of the A⊂B type formula, and A connects the B formula to it.

The application of an analytical rule reduces the problem for the search of some deduction to one or several subproblems of search for auxiliary deductions. For instance, when the purpose of the current subdeduction is obtaining of the $A \supset B$ type formula, the analytical entry rule ⊃ transforms the problem concerned into the problem of an auxiliary deduction of the B formula from the A assumption.

The possibility of the application and selection of the needed search rules are determined by the logical structure of the formulas contained in the current subdeduction being constructed and also in the form of the required conclusion of the given subdeduction.

Upon mastering the technique of natural deduction the greatest difficulty is normally caused by the selection of the needed additional assumptions, the knowledge and the priorities of the related goals, and also the selection of the formulas to which the rules of deduction can be applied in each particular case. The given problem is solved in the following way: when the analytical search procedure is used the required inferences of the subdeducations that arose and all the formulas that can be used in solving of each of the subproblems concerned are clearly stated.

The *DEDUCTIO* programme permits implementation in the dialogue regime the procedure for the search for deduction is an efficient teaching tool, developing the skills of correct reasoning. The program controls the conformity of all the changes of the tree for search for deduction to the system of search rules and, thereby, guarantees the correctness of the deduction constructed. Concurrently with the construction of the deduction, analysis is generated that is demonstrated on what basis each of the formulas was entered. The program permits distinguishing particular subproblems in the course of search providing accessibility of the formulas inherited from other older deductions.

Particularly noteworthy is the specificity of quantor rules for the deduction search. For the synthetic rule of the elimination of the generality quantor (∀) and the analytical rule of the entry of the existence quantor (∃), the idea of *temporal variables* is used, which permits putting off of the choice of suitable terms for their substitution instead of object variables. For that purpose term unification is introduced. The Program ensures the introduction of a new temporal variable with each application of the above rules.

Another idea is associated with the use at intermediate stages of the deduction of the formulas containing *ε-terms*. Due to that no problems arise associated with the varying of the variables and the unambiguity of the selection of the formulas introduced by the synthetic rule of the elimination of ∃ and the analytical rule of the introduction of ∀. The first rule permits adding to it of the A(εαA) formula. The second rule reduces the problem of the search for the formula of the ∀αA type to a subproblem for the search of an auxiliary deduction of the formula A(ε–A).

The *DEDUCTIO* can also be used to teach the technique of the construction of analytical tables. The analytical-table procedure is stated as a special variety of subordinate deduction with a specific system of search rules conforming to the standard reduction rules.

A basic principle of the development of the logics course is demonstration of the variety of pure and applied logic systems. In addition to natural and analytical-table calculi, the axiomatic calculus of predicates and syllogistics are also represented. As an example of applied first-order theories the theory of relative is considered and also the «direct sequence theory» (including the mathematical induction rule) and the theory of Abel groups. As a logical basis of applied theories a technique of natural deduction is used an their natural axioms play the role of unreducible premises accessible at every step of the deduction search.

The *DEDUCTIO* programme is a sufficiently universal tool for the work with logical deductions. It is set up for work with different calculi by means of their description in the original language [1]. The program set includes descriptions of all systems used in the course and also a number of other, including three nonclassic. Along with that, the program is open, permitting a qualified user to modify the available description and create new ones.

The Program supports a single interface working with different calculi, which considerably facilitates the user a transition from one system to another. The visualization regimes demonstrate the entire search tree, a separate subproblem or the skeleton of the tree of deduction search. The substitution of logical and nonlogical symbols of the formalized language by symbol sentences is supported, which permits constructing a deduction consisting of not formulas but rather propositions close to a natural language.

Numerous operations on the modification of the deduction search tree are automatic. Among them are filtration, minimization, generalization, search for the unifier and renumbering of the formulas.

The filtration of the rules for deduction search permits distinguishing only those of them that are applicable in the given context.

Minimization eliminates all the formulas on which the deduction is dependent to simplify the deduction. It also eliminates the subdeductions without allowances to incorporate the formulas belonging to them to the subordinating deduction.

When the regime of formula generalization is on, the rules obtained as a result of the application of the synthetic rule are added immediately after the last of its premise. That renders the added formula available in the maximal number of subdeductions.

When the global substitution of the terms is done instead of temporal variables, a system of substitution may be required, whose performance results in binding of all the subdeductions, or at least the current sudeduction. When the unification regime is on, a search for such a system is done automatically. If the found subsystem permits binding all the branches oaf the deduction search tree, the global substation is performed and also the construction of the deduction is completed. *DEDUCTIO* applies an original algorithm of unification search [1].

All the user actions are protocolled, which makes it possible to run the deduction search step by step or up to the established control points. Thus, one can analyze the work of the students or create demonstration «rollers» provided with commentary.

The Program service also includes saving of both the final and intermediate results of the search, returning to an unlimited number of steps and saving of the deduction in the TeX format, printout of the deduction, etc.

DEDUCTIO is adapted by the authors for the course of deductive logics delivered to the students of faculties of philosophy, including those specialized in logics. At the same time there some experience of using it in other courses. At the faculty of Computational Mathematics and Cybernetics, Moscow University it has been used since 1994 in logics practical classes by I. Gorskaya, using logical systems that are different from those proposed by us. Since 1994 *DEDUCTIO* has been used in the Debrezen Unviersity (Hungary) by A.G. Dragalin. The Program is proposed by the authors and also to the departments of the Izhevsk, Tomsk and Novosibirks Unviersities.

A book by V.A. Smirnov has appeared [2), which can be used as a manual on deductive logics supported by *DEDUCTIO.*

THE MATRIX CLASSIFICATION OF IMPLICATIVE LOGICS THROUGH PROGRAMS MaGIFL4

S.A. Pavlov (Russia)

Among computer training programs the logic program MaGIFL4 is designated for classification of implicative logics.

In logic language the falsity FL4 [2,3] can be defined by 944784 of different implications. For classification 419904 out of these implications in multi-implicative logic FL4 the method of implicative logics, suggested by A.Karpenko [1], was used. It is performed by means of boolean arrays, which can be presented in a form of seven-dimensional hypercube, the tops of which are the subsets of original set of axioms {IBCWK$_1$XN}.

The calculations were carried out by means of elaborated by the author program MaGIFL4 (Matrix Generator for Implication in FL4).

One of the results of the given research consists of a fact, that in logic language FL4 it is possible to conduct proposition correctly and make the logic deductions by 419904 various ways.

Let us show a new formula of by logic complexity, differed from the previous one by absence of supplementary subclass of T.F.-formulas.

The initial profound statements for logic complexity FL4:

1. The concept of complexity is considered and is used only in propositions of the following form: «The suggestion «S» isfalse» (symbolically (-S)).
2. The concept of falsity is considered as original, uncertain concept, which plays a role of logic operator in a formal system. The proposition of truthness of suggestion S is considered as shortening for a statement about the falsity of denial of suggestion S and is written as follows: «The suggestion «S» is truth» (symbolically (|S)).
3. The statement (-S) about a falsity of suggestion S is two-valued, which not each suggestion S must be either truth or false.
4. The truthness and falsity of suggestions with implications are assigned traditionally. The proposition «if S$_1$, so S$_2$» we write symbolically ($S_1 \to S_2$).

<u>*The language of calculus of FL4*</u>

Alphabet: s, s_1, s_2, ... sentential variables;

–, → logic constants;

(,) technical symbols.

The rules of formation of p. p. f. (prepositional forms).

1.1. Any sentential variable is *p. p. f.*

1.2. If A, B is p. p. f., then (–A), (A → B) is p. p. f.

Metavariables: A, B, C, ... for p. p. f. assume the standard agreement regarding to brackets.

Let's introduce the following abbreviations:

D1.1	$f(A) =_{df} -(-s \to -s)$	(a constant «false»)
D1.2	$\sim A =_{df} (A \to f)$	(denial)
D1.3	$\mid A =_{df} - \sim A$	(| an operator of truthness)
D1.4	$\ulcorner A =_{df} -(\mid A \to -A)$	("$\ulcorner$" is read «Truth and not false»)
D1.5	$(A \supset B) =_{df} (\ulcorner A \to \ulcorner B)$	(D - implication)
D1.1	$0(A) =_{df} \sim (A \to \ulcorner A)$	(a constant «zero»)
D1.2	$\neg A =_{df} (A \supset 0)$	(DI - denial)
D2.1	$(A \wedge B) =_{df} \neg(A \supset \neg B)$	
D2.2	$(A \vee B) =_{df} (\neg A \supset B)$	
D2.3	$(A \equiv B) =_{df} (A \supset B) \wedge (B \supset A)$	

Axiom schemes

I.	A1.1	$(A \supset A)$
B.	A1.2	$(B \supset C) \supset ((A \supset B) \supset (A \supset C))$
C.	A1.3	$(A \supset (B \supset C)) \supset (B \supset (A \supset C))$
W.	A1.4	$(A \supset (A \supset B)) \supset (A \supset B)$
K_1.	A1.5	$(A \supset B) \supset (C \supset (A \supset B))$
X.	A1.6	$(A \supset ((B \supset B) \supset A)) \supset (((A \supset B) \supset B) \supset$ $\supset ((B \supset A) \supset A))$
N.	A1.7	$(0 \supset A)$

We add to scheme of classical logic the following ones:

A2.1	$\mid -A \equiv -A$	(reduction of truth operator)
A2.2	$--A \equiv \neg -A$	(reduction of false operator)
A3.1	$\mid(A \to B) \equiv -A \vee \mid B$	(reduction of truth implication)
A3.2	$-(A \to B) \equiv \mid A \wedge -B$	(reduction of false implication)

The rule of deduction:

$$\frac{A,\ (A \supset B)}{B}$$

From this formula of FL4 it is seen that both classical logics and non-classical logics take place over all set of p. p. f. Therewith the operators of classical logics $\neg, \supset$ are the derivatives of original non-classical operators of which are contained in its language, and which takes place over all p. p. f. set, as super classical.

Note, that FL4 is a four-valued generalization of three-valued logics of Lukasevich, distinguished from generalisation of Lukasevich.

The classification of implications.

In order to structure an implicative logic for some implications $\to_{\mid}$ with axioms A_m $(m \leq 7)$ from a set of {I, B, C, W, K_1, X, N} in such a way, that formulas A_m would be the theorems FL4, and a rule of deduction A, $(A \to_{\mid} B)$ / B would be a derivative rule in FL4, it is necessary to fulfil the following terms:

1. The formula $(A \to_{\mid} B)$ must be defined in language FL4.

2. $(((A \to A) \wedge (B \to B)) \supset ((A \to_{\mid} B) \equiv (A \supset B))$ (booleanity).

3. $(A \to_{\mid} B) \supset (A \supset B)$ (conservation of *modus ponens).*

The number of various implications, satisfying this terms, is equal to 419904.

The computing results, obtained by means of the program MaGIFL4, are shown in the following table:

•	Ø	324278	I	38523
•	N	39289	IN	4256

COMPUTER GAMES AS A BASIS FOR LOGIC TEACHING IN SECONDARY SCHOOL

D.V. Zaytsev, O.Yu. Karpinskaya, V.I. Markin (Russia)

The fist stage of this project was realized through the support of «Cultural Initiative» International Foundation in the frameworks of the Programme № FS95-105-200395-101. The project is realized on the base of Moscow gymnasium № 1543.

A logic course for secondary school is presented, which is based upon teaching and developing computer games. The creation of such course allows to overcome the drawbacks of existing system of logic teaching school, it bases the foundation for successful implementation of this subject in the secondary education system.

Currently, the task of wide and steady introducing of logic teaching into secondary school is especially actual. It may be explained both by matured needs of the society in the increase of logic culture and in the increased interest to this science among the trainees and their parents. Recently logic has become a fashionable discipline, its presence in curriculum is now a question of prestige for lycee, gymnasium, special school. However, the situation with teaching of this subject in the secondary school is, not by any means, cloudless. Moreover, if in the nearest future there would not appear serious changes in this field, a situation of the after war years may repeat, when introduced due to the order from above logic and physiology soon have disappeared from school curriculum without any track.

Currently, in the process of logic implementation in the school one could notice two tendencies.

On one hand, there has been stored a certain experience of logic teaching in the secondary school by teachers of the higher school. In most cases, it's carried out without necessary adaptation to the intellectual level of the trainees and to the peculiarities of the school as an educational institution. Let us note, that logic appears, in this case, in the best one, only as one of the educational subjects. Its study essentially transfers into end in itself, not forming steady practical skills of intellectual procedures realization.

On the other hand, the attempts to put the development of logic culture of thinking as a main objective of logic teaching, as a rule, don't bear on the achievements of contemporary logic. This leads towards the absence of strict criterion of used cognitive operation correctness in trainees. As a result, the basic skills of correct solution don't transfer into the skills of acting in problem-situations hat appear in real life.

The turned out situation is aggravated by a set of circumstances, such as the absence of text books on logic for secondary school, that are produced on professional theoretical level; serious lack of qualified pedagogical staff; absence of training and retraining system.

The approach, which is realized in the framework of «Homo Ludens ergo Sapiens» project (Complex programme of logic thinking culture forming with the use of training and developing of computer games), allows not only to overcome the drawbacks of both above mentioned approaches, but also to avoid mentioned difficulties of informational and staff character. The main innovation project idea consists of the synthesis of high theoretical teaching level and aims at the development of practical skills in intellectual operations realization. Such combination may be possible due to the use of training and developing games during mastering of the main parts of logic course.

The logic teaching through computer games utilization requires new methodologies, principally changes the traditional practice of logic teaching. One ought to take into consideration some peculiarities of the educational process.

1. The training becomes active process. The schoolboys obtain a real possibility for self-education and self-control.
2. Due to the game character of training, to the presence of competition elements, an increase of motivation is achieved towards acquisition of logic knowledge and skills. Hence, the motive is present in the content of the activity, but not beyond it. The addressing to the theoretical material is stimulated by the desire to reach success in the game.

3. In the course of the educational process a gradual enrichment of the trainee's knowledge takes place. This is reached through the involvement of trainees into the real problem cognitive situations, through the activities, bearing on the certain game material.
4. Just the same psychological barriers are removed, which impede the material mastering. In the case of «face to faces» competition with the computer, the trainee looses the fear of public mistake.
5. The process of logic knowledge acquisition becomes practically oriented. In its course not pure mastering of theoretical material takes place, but rather mastering of certain skills, i. e. finding the concept for certain subject; generalization of the subjects into a class by picking out of their characteristic features; the correct conclusion on the basis of comprehension of simple and complex statements of logic senses; knowledge of the conditions for their truth or falsity etc.

The utilization of computer games as a basis for the school course of logic allows to decide successfully the staff problem (the games initially contain training moment and control mechanism of the training process itself and of material mastering quality, that prevents possible negative consequences of not sufficiently qualified teaching), and also to compensate the absence of text-books (every game is supplied by necessary "Logic minimum" of knowledge according to the corresponding theme).

The game complex includes the games on the following main issues of the Logic Course: "Concept", "Judgement", "Statement logic", "Syllogisti". Such selection is determined, firstly, by central role, which the above themes play in the logic science, and, secondly, by its practical importance for the development of steady skills of logic procedure realization. Finally, namely these themes are the most difficult for the trainees, and, thus, require enlarged attention and additional training.

All the games are designed, in spite of significant thematic and scenario diversity, according to the similar plan. Each game includes several complicity levels and possibility for preliminary training. Apart from that, a special control text is foreseen, which contains the tasks of all levels. Its fulfilment requires the time, which is usually spent on fulfilment of control or individual work, while the results are fixed automatically that provides the possibility for task control. The games are supplied by support system, which includes the description of the game rules and strategy. They are also supplied by a certain minimum compendium of logic tasks, connected with the game theme, which is necessary for successful solving of the game objective.

Currently two games have been already realized and are in the course of approbation in the secondary school. Other games are in the stage of development.

The first game «*Vibiralochka*» (computer realization of V.I. Shalak) on the «Concept. Volume and content» theme simulates the procedure of finding a concept for a given subject. In the course of the game, practical skills are mastered to determine, whether or not different objects possess some complicated feature. Hence, the trainees obtain a strict understanding of «the volume» concept, of volume element of the concept, of the content of the concept, and of simple and complicated features; the sense of logic connection also becomes clear.

In the beginning of the game the figures of funny people (*«logicanchiks»* or inhabitants of Logic country) appear on the screen. They might be similar or differ by form of body, colour, spirit etc. On the bottom of the creen the description of *«logicanchiks»* is presented, structure of which becomes more complicated from stage to stage. It presents the content of the concept of *«logicanchiks, possessing complex feature of A type»*.

The simple features in the composition of this description are presented by graphic pictures, while logical connections are presented by words of natural language.

The task of the player is to pick out during the shortest time those and only those *«logicanchiks»,* which correspond to the description, e.g. which are included into the volume of corresponding concept. Then the description presented in the screen bottom, is changed. For every correctly realized activity, prize points are added, while every mistake are punished by penalty points.

The given level of the game is finished, when the player makes all the game field free, on which a funny pattern is opened, as a reward for good game. As a whole, the game includes seven levels with through control of time and collected points. A possibility is provided to write down the result and to compare it with the achievements of others.

The control test, including the concepts of the most diverse structures, allows to evaluate the quality of the produced skills. According to the results of testing the mark is turned out, which takes into account the number of correct and wrong actions. The results of test are fixed independently of the trainee's desire and might be used by the teacher as one of the knowledge parameter along with the results of regular control works.

The second game *"Three* cards" (computer realisation of A.E. Novodvorsky, P.A.Novodvorsky and A.B. Smirnov) is aimed at the mastering of the theme "Deductive discussions. Syllogisms". With its help the skills are developed for turning out of logic consequences on the basis of simple categorical statements.

The syllogistic of Luis Carroll is put into its base, according to which the correctness control of the syllogisms is carried out with the help of original diagrams.

The game is realized in the form of trick type card game, in which the display of the trick corresponds to turning out of syllogistic consequence from two premises.

That is the reason for the game name - for the display one ought to have three cards: two of them - with premises and one with the conclusion. Three persons take part in the game, while two of the players - computer personages - present the heroes of Carrd's «Ailis». Each of them has his own game strategy, corresponding, from the author's point of view, to the personage character.

Each player gets cards of different suit on his hands: for premises and for conclusion. After each pass the player must expression the Carroll diagram a logic information of the premise, presented on the selected by him card, or to pick out the conclusion from the premise joint information, if he intends to take the trick.

There is a system of points calculation, analogous to that, used in traditional card games, while a penalty is foreseen for the wrong logic actions.

For the knowledge control a special test was developed, where already without any cards the trainee is presented to «solve» several syllogisms, using Carroll diagrams.

It's necessary to note, that games are oriented for children of 12-15 years old. However, as practice shows, even grown ups take part in this game with pleasure. Thus they may be successfully used in the process of logic teaching n high school institutions.

Other games of the complex, which are currently in the stage of finishing off and selection of the game material, are also developed according to scenario. These include both roulette, «puzzles» and even «gallivantings». In the prospect it's supposed to create complex set of training games on logic, which is included into envelope, purposed for Windows.

Apart form this, the envelope would include several accessories, which make it easier to use the game complex in the frameworks of united school course on the base of computer classes. Moreover, it's supposed to write a special educational supplies on logic for secondary school, oriented towards the developed by the authors computer games, and also towards the preparation of methodical and didactic materials for teachers, who work in this programme.

The game complex may be implemented into the learning process not only in the form of logic teaching as an independent learning subject. It may be also used in the school informatics course for supporting of the essential line named "Formation of readiness to the information technology utilization and development of logic thinking, attention and memory" as well as in the work with the school boys in the extra lesson-time (creative hours, facultative, self preparation and self education, testing of intellectual developments of the trainees).

COGNITIVE COMPUTER GRAPHICS AND LOGIC OF SCIENTIFIC COGNITION

A.A. Zenkin (Russia)

1. INTRODUCTION: NEW CRISIS OF FOUNDATIONS OF MATHEMATICS

The proof theory is one of the most abstract and complicated sections of modern logical science. Remarkable successes of mathematical logic and meta-mathematics (or what is the same - of the proof theory) in 20-th century caused an illusion, that a theory of logical (deductive, certain) conclusion, whose foundations have been still laid by Aristotel, gained its final completion in the advanced theory of formal axiomatic systems. Really, we say, that within the bounds of some formalism F formulae (statement) X_n is a derivable (provable, true), if there is such a sequence of formula from F

$$X_1, X_2, X_3, \ldots, X_i, \ldots X_{n-1}, X_n, \qquad (1)$$

that a) any formulae X_i in (1) is the axiom or b) any formulae is derived from formula preceding it and c) formulae X_n is the last one in (1). Methodological clearness and conclusiveness of similar definition of logical (and mathematical) *deductive* authenticity of formal considerations seemed final and fixed for a long time. But science (true science) is full of paradoxes and sudden «points of bifurcation»: the theory of formal systems created a theory of algorithms and algorithmic languages, forming a «physiological basis of a present-day machine «intellect» - this highest (I don't assert it in the absolute sense) presently achievements of natural intellect. In this case, we can observe remarkable metamorphoses in the «technology» itself of intellectual deflection of «material and spiritual reality». Today' science is impossible without computers, and modem computer system without computer graphics is absorbed as horse carriage on a runway of an aerodrome. In short, today not only scaling computations, and computer «pictures» become important (and often inalienable) element of a mathematical proof - this historical extremum-rigid polygon for verification of the logical authenticity paradigm itself. In this connection a question about the way how a logical status of the formal proof is transformed, if one (or some) from X in sequence (1) will be replaced by results of multi-hour computer super-calculations or graphical equivalent of such calculations - one or another computer «picture», is not useless by no means. Depending on the answer to this question, mathematicians are today divided into two camps very far from unanimity. One half of mathematicians, mainly connected with a world of advanced computer technologies, believe, that «computers transform methods themselves, by means of which mathematicians devise and prove new ideas». This point of view is most completely expressed by John Horgan in his bright article «Death of Proof» [1]. This article made great noise in the mathematician society and caused multiple and not always benevolent comments. The most bright representative of «radical opposition», i.e. in this case, the most compromiseless adept of the traditional *pro-computer* mathematics was a famous specialist in the field of the algebraic geometry Steven Krantz, which in his bright article «The Immortality of Proof» [2] advance the following three main slogans: 1) traditional mathematical proof is immortal in the sense, that it gives us the absolutely authentic knowledge, which «is a truth today, tomorrow and always», while knowledge obtained with the aid of computations or by analysis of computer pictures can be arbitrary plausible and probably-true, but it will never gain a status of *certain* - true knowledge; 2) computer can be used on secondary technical stages of mathematical considerations, but computer will never be able to prompt to a skilled-mathematician (in its traditional sense) such a new idea, about which he will not be able to guess .independently, i.e. without use of computer and in any case 3)»computer pictures proves nothing» and they will never be able to serve as an argument of a rigorous mathematical proof (in its traditional sense.

We will consider only several logical problems, connected with the third most peremptory slogan of Krantz: show, that under the *certain conditions* . computer pictures can nevertheless serve as quite legitim arguments of absolutely rigorous proofs of general mathematical statements (GMS).

I also note, that the most part of logical and mathematical results, described in this article, are obtained with the aid of computer system DSTCh, based on a *Cognitive Computer Graphics* (CCG) concept. CCG - in contrast to more usual *illustrative* (or photo-realistic) computer graphics - is a *knowledge-creating* or, more accurate, graphics, *favouring creation of new knowledge* ((at the present time, naturally, in head of man).

The CCG system of DSTCh is a Dialog System for CCG-researches of problems of an additive number theory - one of the most abstract (and, consequently, the most extremum for employment of wny graphics) sections of the advanced fundamental science. The unique experience of practical creation of essentially new knowledge in the field of modern number theory by means of a CCG-system of DSTCh, is used in creating a *training* version of this system, in particular, for special course "Authentic Conclusion on Non-verbal Knowledge".

2. PROOF OF GENERAL MATHEMATICAL STATEMENTS WITH THE AID OF COMPUTER

Consider *general* (in sense of traditional classic logics) statement of $\forall_n \geq P(n)$ type for any $n \geq 1$, i.e. statement «for *all* values of natural parameter n=1,2,3 and so on, predicate P(n) is true". On one hand, the traditional mathematics assumes, that GMS of $\forall_n \geq P(n)$ type for any $n \geq 1$ are provable only by the *complete mathematical induction* or by means of *deductive conclusion* from more general statements (for example, from axioms of the appropriate theory). On the other hand, it is quite evident, that it is impossible to prove the truth of such GMS, if for this purpose it is necessary to carry out the successive verification of truth values of predicate P(n) for each value from the infinite set of natural numbers $n \geq 1$:

$$P(1), P(2), P(3), \ldots, P(n), \ldots \qquad (2)$$

In principle, in this case application of computer changes nothing: step-by-step - i.e. from *n* to *n+1* - travel of Infinity is and for any most powerful supercomputer - from the point of view of this Infinity - the same absorbing running in place, as for man.

However, hence it is not follows, that such a GMS are probable only analytically , i.e. without used of computers. Solution of known problem of "four paints" [4] is the most bright and sensational example of proving GMS by means of a computer. Analysis of this example (and naturally several others) allows us to formulate in the explicit form the following sufficiently-evident general method of solving GMS *with the use of computer,* which is naturally to be later called a method «Truncation of Infinite Tail» (TIT) in sequence (2), accounting for its specific features.

Method "Truncation of Infinite Tail"

1. *Prove* analytically, i.e. deductively the *existence* of a *threshold* natural number, designate it as n_0: exists n_0 for any $n>n_0$ P(n).
2. *Determine* (*as* a rule, *analytically*) the *value* of this threshold number no (very nontrivial moment in all theoretical-numeric problems).
3. *Prove* the truth (check with the aid of computer the correctness) of P(n) for *finite number* of cases: for any $\forall n \leq n_0$.

   If stages 1-3 are successively implemented, then thereby
4. We *proved,* that GMS P(n) for any $n \geq 1$ is true.

Today we can assume sensational solution of once more mathematical problem - the known Waring Problem for sums of bi-quadrates (forth degrees) of not-negative integer number, as already classic example of successive application of the TIT method. A *hypothesis* about the fact, that any natural number can be represented in the form of some sum of 19 bi-quadrates is known more two thousands years. However, only in 1986 the international group of mathematicians and software engineers proved the correctness of this - one of the oldest "General Mathematical Statements". In so doing, it is worth underlining, that *existence of* threshold number no has been yet proved in 1925 by Khardi and Littwood (1 stage) - naturally analytically. Once more than half century later Balasubramanian, Deshouillers and Dress [5] first set the order of this threshold number (2 stage): with the use of advanced methods of analytical number theory authors shown, that no is equal approximately 10^{367}. Then, be means of computers they proved (verified) the truth of P(n) and for all $n \leq n_0$.

Hence follows the authentic truth of P(n) for *all* $n \geq 1$. Note, that not only the stage of analytical proof of the truth of P(n) for all $n>n_0$, but also the stage of computer proof of the truth of P(n) for *finite* number $n \geq n_0$ with so magnificent value of the threshold number itself, is a non-trivial one.

3. SUPER-INDUCTION METHOD - NEW METHOD OF PROVING GENERAL MATHEMATICAL STATEMENTS WITH THE AID OF COMPUTER AND COMPUTER PICTURES

Before coming to description of the super-induction method, make one important methodological remark, concerning the GMS notion itself. Till now we considered GMS in its classic form: $\forall n \geq 1$ P(n), that is P(n) for *all* n = 1,2,3,... . However, in mathematics there is a more spread and natural case, when some statement is true not for all n belonging to N (here N designates a set of natural numbers), and for all n belonging to N, except several n belonging N_e, where $N_e = \{n \geq 1 : \neg P(n)\}$ is the so-called *exclusive* set of values for natural parameter n or set of *counter-examples* for predicate P(n). It is considered, that the specified-type GMS is *proved completely,* 1) if proved, that it is true *for all* n belonging to N, except n belonging to N_e and 2) if *structure* of exclusive set N_e is determined *explicitly,* i.e. it is known what values n belong to N_e. It is evident, that specified here sense of GMS is *generalisation* of the traditional one: if exclusive set is empty, then we return to traditional form of GMS in the shape of P(n) for all $n \geq 1$. We can give a variety of examples, showing, that in mathematics just these exclusive values n belonging No often contain information, which is the most valuable for further investigations.

As it was mentioned above, we have studied the logical structure of such proofs with the aid of a man-computer CCG-system of DSTCh, based on conception of *cognitive computer graphics* [3,6,7]. These investigations allowed us to see, *formulate and substantiate a new method* of proving GMS [7]. What about its name, there were few alternatives: the nearest analogue - classic deduction according to J. S. Mill' - presents a *plausible* conclusion "from *particular* to general", that is why it was natural to name an *certain* conclusion "from *unit to general»* just *SUPER-induction.* We will specify its complete and rigorous statement.

Super-Induction Method

1. *Construct (i.e.* devise) and *prove* analytically *(deductively)* the *conditional* statement of the following rather exotic form:

$$\exists n^* Q(n^*) \rightarrow \forall n > n^* P(n),$$

with $Q \neq P$ is the *essential* condition.

2. *Search* (usually with the aid of a computer, but may be on computer picture and there is also a possibility in principle to carry out the traditional search manually) *exotic* in the definite sense *-unique* - natural number n*, having property Q (usually Q - some combination of nontrivial theoretical-numeric properties).

If we can find such a number (this result is not generally guaranteed beforehand), then

3. *Proved the truth of unit antecedent* $\exists n^*Q(n^*)$ of our implication.

4. From the proved truth of statements $\exists n^*Q(n^*)$ and $\exists n^*Q(n^*) \rightarrow \forall n \geq n^*P(n)$, it follows according to *modus ponents* the *certain truth of general consequent* $\forall n \geq n^*P(n)$.

5. *Perform* successive verification (usually on a computer, but may be done by a picture or even by means of manual count) of truth values of predicate P(n) for all $n \leq n^*$ and *explicitly express* (create) finite exclusive set $N_e = \{1 \leq n \leq n^* : \neg P(n)\}$.

If similar verification of P(n) is implemented for every n=1,2, ..., n* (what is not always performable for great n* even with the aid of the most powerful supercomputers), then:

6. *Proved and absolutely strongly the following GMS,* $\forall n \geq 1 P(n)$, кроме $\forall n \in N_e = \{1 \leq n \leq n^* : \neg P(n)\}$.

So, the essence of the super-induction method consists in substitution of direct absolute and therefore usually complicated *analytical proof* $\forall n \geq 1 P(n)$ for proof of two statements: some *conditional* statement $A \rightarrow B$ and *unit* statement A. Such a substitution is connected with appearance of very important degree of freedom:
we can now carry out the choice of statement A so, that to maximally simplify both the stage of analytical proof of our very nontrivial implication A ->B and subsequent computer proof of unit statement A. Such a proof of unit statement A can be very often reduced to imposing some CCG-image of corresponding abstract mathematical object and *make the proof clear* (i.e. directly visible by eyes) - in compliance with well-known criteria "clearness and distinctness" (Descartes and Leibniz), "evidence of initial intuition" (Kronecker and Brauer), while obtaining certain mathematical knowledge.

Consider two examples of rigorous proof of GMS by means of the super-induction method and ... a computer picture.

Example 1

Fig. 1 shows colour-music (of course, on a computer screen) CCG-image (pythogram) of new theoretical-numeric object - invariant set Z(1,3) of Generalized problem of Waring (GPW), devised with the aid of CCG-approach. This pythogram is «read» as a page of standard book from left to right and from top to bottom, but only with the use of numbers: 1,2,3 ... and so on with 21 numbers per row. Black squares-numbers are elements of set Z(1,3). However, we don't know, if we see in front of ourselves all elements of set Z(1,3) and there are other black squares «beyond frame"? In other words, this computer picture allows us to formulate sufficiently plausible *machine hypothesis* about the fact, that number 149 is the maximal (last) element .of set Z(1,3). Show, under which conditions one *and the same* computer picture can become an *argument of strong* (in the sense of traditional mathematics criteria) proof of this hypothesis.

The sought implication A ->B is the following statement: "*if* (A) exists (though one) black square, which is directly followed by at least 7 white squares, *then* (B) and all subsequent squares are white". This implication was

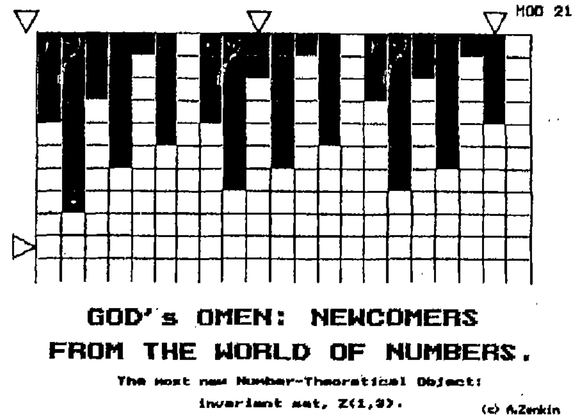

Fig. 1. Pythogram of invariant set Z(1.3) for Generalized problem of Varing

proved analytically, naturally, in more general form [8]. In this case, it remains to prove the truth of *unit* statement A, i.e. to *find* such a black square, which is followed by at least 7 white squares. For this purpose, look at pythogram, see a black square marked (only for demonstration purposes) with a white asterisk and showing natural number 149, which is followed by a row of white squares in a number, evidently exceeding 7 (you may not count) - it is a very essential moment. Thus, *unit* statement A is proved (just proved) not only by a *clear* method, but by a method directly **seen** *by eyes*. Hence, according to modus ponents it follows, that (B) marked square-number 149 is really the last black square, as set Z(1,3) is *finite* and we see all its elements in front of ourselves. It is not difficult to see, that - not in direct and in «usual» figurative sense - that we prove the following GMS: *«Any* (notorious *all)* natural number n>149 does not belong to set Z(1,3) and among all numbers n<149 only the following black squares-numbers (see picture): 1-6, 8-13, 15-20, 22-25, 27, 29-32, 34 and so on are elements (here matching with *exclusive)* of set Z(1,3) - the rest elements of set Z(1,3), not written here explicitly, we can *physically see* on pythogram in Fig. 1.

Example 2

In Fig. 2 we already see an entire cartoon film about application of the super-induction method for visual proof of known theoretical-numeric theorem, proved in 1933 by American mathematician G. Pall [9] with the use of methods of usual pre-computer mathematics. Without going into details note, that this proof takes several pages of compact text. The essence of general statement, proved by Pall, consists in the following: «With $s \geq 6$ only numbers s+1, s+2, s+4, s+5, s+7, s+10, s+13 have theoretical-numeric property P(n)» (any one, who wishes to familiarise himself with details of this proof can do it in [1,8]). Within the bounds of the super-induction method we «devised» and proved analytically the following implication: «if (A) there is a natural number n*, simultaneously representative by sum of first, second, third, fourth and fifth squares of integer numbers, then (B) for any n>n* the square is white». Then by means of a computer we found the minimum of these numbers:

$$n^* = 169 = 13^2 = 12^2+5^2 = 12^2+4^2+3^2 = 11^2+4^2+4^2+4^2 = 10^2+6^2+4^2+4^2+1^2.$$

Thus, both A and $A \rightarrow B$ are proved. Consequently, according to *modus ponens* B is true, i.e. there are no white squares *«behind"* number 169 (marked with asterisk on pythograms with s≥4). Everything, that took place *«prior to it»* is before your eyes: if take into account, that the first number on all given in Fig. 2 pythograms is natural number s+1, then on pythogram s+6 we see, that only numbers 6+1, 6+2, 6+4, 6+5, 6+7, 6+10, 6+13 are black squares-numbers, having property P, i.e. we see *evident proof of* Pall theorem. As it is known, the Pall theorem was. the first step towards very nontrivial generalisation of

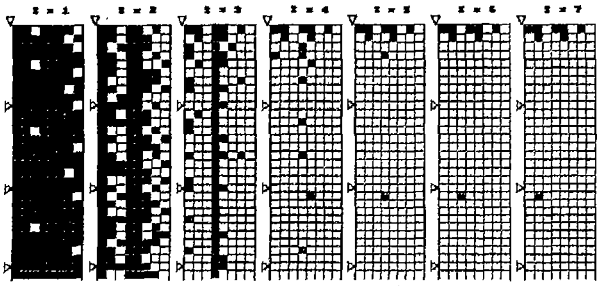

Fig. 2. Visual proof of theorem of G. Pail: g(1,2)=6 or on language of cognitive graphics «It is sufficient to use six frames for stabilising the number of black squares». Here sign «» in 21-th row is used for marking outstanding number n*(1,2)=169, and the first number in the row of every s-th pythogram is number s+1 for all s from 1 to 7.*

known problem of Waring. However, more than half-century have passed before we can see such a potentiality and do the next steps towards this direction: only the CCG-approach allowed us to *see* (in direct sense of this word), that Classic problem of Waring (CPW), which was researched for more than two hundred years by Euler, Lagrange, Gauss, Legendre, Gilbert, Hardi, Vinogradov and many other outstanding mathematicians of XVIII-XX centuries, presents only 0 storey of some essentially more infinite-storey theoretical-numeric structure - Generalised problem of Waring. It is evident, that for travelling between "storeys" of this new «mathematical Babylon" a new technology of "altitude ascent" was required and I could not make bold to put down to "blind" occasion the wonderful Fact, that just the super-induction was the very universal and high-efficient "lifting mechanism", which enables us to carry out successive, reliable and safe lifting over multiple "storeys" of this far-leading problem [8,10]. In any case, from such an altitude we may look over many quasi-scientific palisades, which seem absolutely inaccessible and eternal.

4. MAIN DIFFERENCES BETWEEN SUPER-INDUCTION METHOD AND ITS NEAREST ANALOGUES

Let us briefly dwell on basic differences between the super-induction method and its closest analogues.

a. Mathematics rather often uses a method of substituting the direct - and, as a rule complicated -proof of GMS, for example, B to a proof of some *conditional GMS* of A → B type. The proof of the Great Ferma theorem (GFT) is a bright example of similar substitution: as is known in 1986 American mathematician Kenneth Ribet proved the truth of *implication:* (Hypothesis of Taniyama-Shimura) → GFT, and several years later another American mathematician Andrew Wiles analytically proved not GFT at all - as many think - and «only» Hypothesis Taniyama-Shimura, i.e. *antecedent* of this implication. But, as we know, this is sufficient to conclude according to modus ponens the *certain truth of consequent,* i.e. of famous GFT. So, in this proof GMS of GFT (B) is concluded analytically from *more general* GMS - Hypothesis of Taniyama-Shimura (A) and, naturally, that the proof of GMS of such degree of generality is possible only *analytically,* what was demonstrated by A. Wiles. Within the limits of the super-induction method situation is quite different: GMS (B) is concluded (deduced) also analytically, but from *unit* statement (A), whose truth can be completely established (and really done) with the aid of a computer or even with the use of colour-music cognitive computer images-pythograms.

b. Within the bounds of the TIT method (see above) first, we *analytically prove the existence* of a threshold number no, then (again analytically) determine the value of this threshold number and only at the final stage verify values P(n) on end range [1, n_0] by means of a computer. In the super-induction method we, first, devise *exotic implication* (this stage is missing in the TIT method), then we *analytically prove the truth of this implication* (but not the existence of a threshold number, as in the TIT method); and at last we *find* with the aid of a computer (or in simplest cases - with the aid of CCG-pythograms) the *unit* unique natural number n* with assigned set of theoretical-numeric properties Q(n*). We don't prove its existence and even can't guarantee it. But, if such number n* *exists* and is we can find it, then we «only» prove *the truth on unit antecedent* (this stage is missing in the TIT method) and further we act similarly to the TIT method and prove the required GMS by means of a computer or corresponding pythogram).

c. Consider a method of complete mathematical induction in its most general form [11]:

$(P(n_0)\ \&\ (\forall n \geq n_0(P(n) \rightarrow P(n+1)))) \rightarrow \forall n \geq n_0\, P(n)$.

Here there is some analogue of a "threshold" number $n_0 \geq 1$ (initial step of induction), there are two implications, however, there is only one predicate P(n). At the same time, the specific feature of the super-induction method is presence of just two non-identity predicates in its implication: predicate Q in antecedent of implication and predicate P - in its consequent. In this case, as we earlier underlined $Q \neq P$.

Thus we may ascertain, that the super-induction method essentially differ from all its nearest analogues.

5. CONCLUSION: CCG-MAKING OF CARTOON FOR TRUTH BEARS CONSENT

As it is known, great mathematician and philosopher Leibniz was a principal opponent of proving problems by discussion: "What we discuss for? - Let us sit down and *calculate...* the best solution!". So or almost so he said. New information technologies, possibly, will also soon create new methodology of visually proving the logical and mathematical statements and .respectively, correct a theory of taking decisions of the founder of many mathematical calculus: "What we discuss for? -Let us sit down and *watch a* cognitive colour-music cartoon film about the best solution of problems, which separate us at present!".

Appreciation. *The author express sincere thanks to academics G.S. Pospelov and D.A. Pospelov, and professors V.A. Smirnov, E.D. Smirnova, Yu.I. Ivliev and A.G. Barabashev for useful discussion of a number of problems, covered in this work. He also thanks Anton Zenkin for creating software complex DSNT, with the aid of which he could obtain new scientific results and create all listed here (and many other) pythogrammes of theoretical-numeric objects. This work is supported by grants of International Scientific Foundation of John Soros (No ZZ5000/114), Russian Scientific Foundation Pertaining to the Humanities (No 96-03-04165), Russian Foundation for Fundamental Researches (No 96-06-80657) and the Ministry of Science of RF (Project No 05.04.1221).*

Part II

MATERIALS OF WORKSHOPS

Within the framework of the Congress, besides the Plenary and commissions meetings, the workshops on the following 12 topics were made:

1. Information Superhighways and Education

(part I: Perspectives and problems related to development of world and regional common information space for the field of education; part II: From information literacy to information culture).

2. The Psychological-pedagogical impact and the medical consequences of the application of modern information and communication technologies.

3. The software environment - A perspective for effective involvement.

4. Transfer of knowledge and skills through information and communication technologies.

5. National policy - transfer of technologies.

6. Individual distance training.

7. Analysis of UNESCO/IFIP documents published in 1994-1995 (part I: "Informatics for secondary education – A curriculum for schools"; part II: "A modular curriculum in computer science").

8. Logics, Informatics and Education.

9. Information technologies and humanities education.

10. Development of pre-university education via modern information technologies and methods.

11. Medicine: new approaches to knowledge acquisition and improvement.

12. Forming integrated world data bases and knowledge about planets of the Solar System and their use in research and education.

Among supervisors of workshops there were famous scientists, methodologists and organizers of education, among them:

- **David Walker (United Kingdom) - Consultant of DW Associates Company;**
- **Peter Waker (South Africa) - Consultant of IFIP Technical Committee 3 - Computer Olympiad;**
- **Alain Meyer (France) - Director of TV-education Centre of the National Conservatory of Arts and Trades (CNAM);**
- **Tom J. van Weert (he Netherlands) - Director of School of Informatics, Faculty of Mathematics and Informatics, University of Nijmegen, Chairman of Working Group 3.2 IFIP;**
- **Harald Schütz (Germany) - Research Consultant of Deutsche Welle Internet;**

- **K.K. Kolin (Russia) - First deputy director for Research Institute of Problems of Informatics (Russian Academy of Sciences);**

- **Yu.N. Afanasiev (Russia) - Rector of Russian State University for the Humanities;**

- **A.L. Semenov (Russia) - Vice-chairman of Moscow Committee of Education, Rector of Moscow Institute on Professional Development for Educational Staff;**

- **N.N. Evtikhiev (Russia) - Rector of Moscow Institute of Radio Engineering, Electronics Automatics (Technical University).**

Below we expose the main results of the workshops, summaries and recommendations proposed by participants of these workshops.

INFORMATION SUPERHIGHWAYS AND EDUCATION

Supervisors:
K.K. Kolin,
Sh.Sh. Chipashvily,
S.A. Khristochevsky (Russia)
H.Schütz (Germany)

The purpose of the workshop was a *discussion on problems of creating a «uniform» information area for education sphere on the basis of modem and prospective information and communication technologies (including superhighways); problems, connected with school education and balance of «fundamentally» in curricula and «racticality» in the course of Informatics.*

THEMES OF STATEMENTS:

1. *Search of a balance of demand and supply in net education.* (M.A. Guriev, Deputy chief of Department on Analysis and Forecasts of the President administration Analytical Department, Russia).

2. *Role of WWW-technologies in education.* (A.B. Nikitin, Specialist of Decision Development Department of C.I.S. Computer IMC, Russia).

3. *Social and cultural effects of Internet in the countries with developing market economy.* (A.Yu. Zotov, President of Board of Regional Public Centre of Internet Technologies, Russia).

4. *Information superhighway and distance learning.* (Jan Wibe, Chairman of Working Group IFIP 3.6 «Studies in the field of distance learning», Norway).

5. *Virtual computer club.* (G.A. Pachikov, Vice-president of «Paragraph» JSC, Russia).

6. *Problems of distance learning and application of Internet in the sphere of education in regions and districts of Russian Federation.* (E.K. Henner, Head of Information Chair of Perm State Pedagogical University, Russia).

7. *Deutsche Welle - first German broadcaster, suggesting regular broadcasting by Internet.* (H. Schutz, Associate of Deutche Welle Internet, Germany).

The following participants took part in the discussion:

- D.O. Smekalin - Head of Department of .Ministry of Education of the Russian Federation;
- A.D. Ursul - President of Noosphere Academy, Head of the Chair of Ecology and Noosphere Studies of Russian Academy of State Service at the President of Russian Federation;
- S.A. Khristochevsky - Head of Department of Reserach Institute of Problems of Informatics (Russian Academy of Sciences);
- Betty Collis - Chairman of Working Group IFIP 3.3 "Researches in the Field of Education Informatics", The University of Twente (the Netherlands);
- Mike Aston - Director of the Advisory Unit "Computers in Education" (UK);
- A.Yu.Uvarov – Head of laboratory "Telecommunications in Education" of Scientific Council on problem "Cybernetics" of the Russian Academy of Sciences;
- A.Yu. Kushnirenko - Author of the text-book on informatics (Russia);
- I.V. Sokolova - Head of the Chair of Moscow State Social University;
- A.V. Petrov - Head of the Chair of applied informatics of the Russian Academy of State Service at the President of the Russian Federation.

As a result of discussion, new trends were revealed in the education informatics and recommendations for different regions considered on the problems of applying informatics to the education. The experience of various countries was used as a base for discussion.

It was pointed out that the necessity exists of providing an access to information superhighways for a great number of educational institutions. The participants marked the necessity to make a demarcation line between the commercial and scientific information flows, as well as to assert "self-restriction code", at the treatment of the information superhighways for ensuring complete satisfaction of educational institutions requests. The reporters expressed the idea of introducing special courses in the higher classes of secondary schools, colleges and universities with the aim of teaching proficiency of using information superhighways, including principles of navigation through the information world, and also the expedience of making changes in curricula for organizing independent students researches with using of Internet.

The participants also supported the idea of necessity to intensify educational process, as this idea is a strategic one for developing the entire educational system on the threshold of 21st century and for future civilisation progress as well.

High importance of developing new principles for studying informatics as a fundamental scientific discipline was emphasised by analysts.

It was recommended for UNESCO and States-members to support an initiative of Russia concerning new principles of studying informatics in higher and secondary schools. These principles should provide arrangement of new ideas connected with the role of information and information processes in nature and society. In this case, much thought should be given to the fundamental laws of informatics implementation in the social life, the effect of the above process on both social economic structures and the human being role in the modem society. For this purpose, the decision was taken to carry out an international project "Informatics -2000» under aegis of UNESCO, which should result in development of the improved module program for studying fundamental principles of informatics for universities, technical and humanitarian institutes, and also lyceums and colleges.

It was established that information society creation demands an equal access to the information at any area of the world and it should be a key point of educational systems in various countries taking into account all the abundance of national and religious traditions.

It was recommended to introduce into curricula of; pedagogical universities and colleges the new profession for teachers: teacher-methodologist (script writer) on creating and using training multimedia products and "Informative culture" course as well.

It was offered to create under the aegis of UNESCO regional and national centres of system investigations on applying informatics to secondary school, in which data on researches and applications of information facilities during training process should be systematized and generalized.

The participants recommended for States-members to develop national programs on applying informatics to education. One of elements of such programs should be the state support of expensive preparation of electronic multimedia manuals.

It was recommended to begin under the aegis of UNESCO the development of the program "Electronic Art Centre in School" (another name - "School Electronic Library").

Workshop 2

THE PSYCHOLOGICAL – PEDAGOGICAL IMPACT AND THE MEDICAL CONSEQUENCES OF THE APPLICATION OF MODERN INFORMATION AND COMMUNICATION TECHNOLOGIES

Supervisors:
I.V. Robert, A.M. Bolshakov
(Russia)

The purpose of the workshop was a *discussion on problems concerning psychological and pedagogical effect and medical consequences of applying modem information and communication technologies.*

THEMES OF STATEMENTS:

1. *Teaching computer programs and problems of psychological health.* (V.V. Rubtsov, Director of Psychological Institute of Russian Academy of Education, I.M. Ulanovskaya, Senior researcher of the above Institute, Russia).

2. *New information technologies in education and the state of pupils' health protection.* (A.A. Baranov, Director of Scientific and Research Institute of Hygiene and Prevention of Diseases of Children, Juveniles and Youth, Russia).

3. *Information-subject medium with built-in elements of training technology on the basis of applying facilities of informatization and communication: psychological and pedagogical effect: prospects of applications.* (I.V. Robert, Head of the Centre for Informatization of Education of the Institute of General Secondary Education of Russian Academy of Education, Russia).

4. *System for protecting pupils' health with the use of new information technologies.* (A.M. Bol'shakov, Head of the Chair of Informatics and Health Protection of Sechenov Moscow Medical Academy, Russia).

5. *Medical problems of organizing studies with the use of personal computers in pre-school child institutions.* (L.A. Leonova, Head of Laboratory of Age Physiology of Russian Academy of Education, Russia).

6. *Physiological cost of applying automated training systems on the basis of personal computers in training of medical personnel and factors, affecting it.* (V.R. Kuchma, Head of a Chair of Sechenov Moscow Medical Academy, N.A. Bobrishcheva-Pushkina, Senior lecturer of the above Academy, Russia).

7. *Special features of differentiation of the content for informatics training at the last stage of school.* (A.A. Kuznetsov, Chief researcher of the Centre for Informatization of Education of Institute of General Secondary Education of Russian Academy of Education, T.A. Zakharova, Consultant of the above Centre, Russia).

8. *Problem of the adaptation of training programs for individual features of a trainee within the frames of ecological paradigm.* (A.S. Molchanov, Head of the Laboratory of the Institute of System Analysis of the Russian Academy of Science, V.N. Krut'ko, Head of laboratory of Moscow Sechenov Medical Academy, A.M. Bolshakov, Head of the Chair of Informatics and Health Protection of the above Academy, Russia).

9. *Actuality of international education projects organization, with using of new information and communication technologies, with the aim of forming the outlook of juveniles (hygienic aspects, AIDS, drugs) and developing the active ecological attitude of a child as a member of world society.* (T.B. Malykh, Lecturer of the Military Aircrft Engineering Academy, Russia).

10. *Computer and PC user health.* (I.G. Getiya, Head of the Chair of Ecology and Safety of the Moscow State Academy of Instrument Engineering and Informatics, V.K. Shumilin, Senior lecturer, Russia).

11. *Hygienic aspects of students and pupils work with video terminals.* (E.A. Geltishcheva, Senior researcher of Moscow Erisman Scientific and Research Institute, Russia).

The following issues were discussed:

- influence of applying new information technologies (NIT) on pupils psychological health and development of system for protecting pupils health at NIT applying;
- hygienic aspects of work of trainees with video terminal;
- medical aspects of training with the aid of computers in pre-school institutions;
- psychological and pedagogical effect of applying information-subject media with built-in elements of training technology, developed on the basis of information and communication aids;
- adaptation of curricula to individual features of pupils within the frames of the ecological paradigm;
- organization of international educational projects, using new information and communication technologies with the purpose of creating of the outlook of juveniles and developing the active ecological attitude of a child as a member of world society.

As a result of discussion there was developed a declaration for "Psychological and pedagogical impact and medical consequences of applying modem information and communication technologies" UNESCO project. The main objectives of the project are as follows:

1. Performance of short-term pilot investigations of problems how NIT effect on development and state of health of a trained person in pedagogical, psychological and physiologic-hygienic directions.

2. Development of psychological and pedagogical, physiological and hygienic recommendations on applying NIT for developing the personality of a trained person, preparing the rising generation for living under conditions of the modem society and creating teaching systems, connected with general medical problems of the world society, allowing for psychological, cultural and ethnic peculiarities of perception for children and juveniles.

3. Development of courses for training and rising the level of skill of pedagogical personnel on problem of applying NIT in education, accounting for psychological, cultural and ethnic peculiarities of trained persons. One of such courses provides teaching of applying advanced technologies, ensuring information interaction on the basis of multimedia, telecommunication networks and technology "virtual reality". Scientific and educational organisations of a number of countries: Russia, United Kingdom, Bulgaria, Malaysia, Georgia can take part in this project.

4. Development of unified international standards of the pedagogical and ergonomic quality of hardware, information and communication aids, used in educational purposes.

Workshop 3

THE SOFTWARE ENVIRONMENT - A PERSPECTIVE FOR EFFECTIVE INVOLVEMENT

Supervisor:
D. Walker (United Kingdom)

The purpose of the workshop was *showing-up of points of view for representative of educational and industrial spheres for determining prospects, needs, restrictions and possibilities for co-operation. The main attention was paid to opinions of users, hardware and software engineers, companies engaged in hardware production.*

There were noted great scales of the software commercial market with a scope of operations up 60 billion dollars per year. It's worth mentioning that about 30 % of these operations cover the educational sector, what makes education an important part of the market. At the same time, end-users still slightly influence on the developed assortment of products, as production branches are firstly guided by scales of market and its potentiality. The software is significantly affected by the companies-developers.

A review of software and hardware market was made. It was noted, that modern program environment is not a completely integrated in the market. There is a need in creating a model, which can let user gain a possibility to take active part in the integral development of the market segment, meeting relevant needs and giving specific results. It was indicated the necessity to achieve mutual understanding with respect to curricula for all educational specialists and the requirement in realistic and effective joint projects in educational and industrial spheres, and also in creating infrastructure for supporting such a program for strengthening active partner co-operation.

Workshop 4

TRANSFER OF KNOWLEDGE AND SKILLS THROUGH INFORMATION AND COMMUNICATION TECHNOLOGIES

Supervisors:
A.L. Semenov,
E.I. Bulin-Sokolova,
P.A. Yakushkin (Russia)

The purpose of the workshop was to *familiarize participants of the Congress with new directions in the field of educational information and communication technologies with an accent to integrated solutions for primary and secondary school and with new content and integrative tendencies of the education field «Technology».*

The following participants took part in the discussion:

- S.F. Soprunov - Head of LOGO-department of the Institute of New Education Technologies (Russia);
- G.B. Shabat - Teacher of mathematics, Lyceum "Vorob'evy gory», President of Club of experimental mathematics (Russia);
- David A. Tomas - Professor of mathematics, Montana State University (USA).

General directions of workshop were as follows:

- information technologies for teachers of any teaching subjects;
- computer aid mathematics and language teaching in primary schools;
- time and space notions in the "Technology" field;
- Moscow regional policy of introducing information technologies into schools.

These directions consider ways of applying computer environment to intensify using of visual methods and motivation of pupils during the classes; problems of adaptation of program environments to regional and national curriculum; unique structural approach aimed at development of high-level thinking and abilities for creative solution of problems; information processing facilities and integrative tendencies; strategic planning, experience of realisation of specific projects and programs of retraining of teachers.

The participants of the workshop took a visual idea and real experience of work in the information environment of the educational institution, including those on such classical directions, as studying natural sciences, geometry, mother and foreign languages, as well as of design-research approach, based on creative developing environments. The participants familiarised themselves with the best examples of software and hardware of a number of firms and gained an idea about practical ways to cooperation on introducing advanced information technologies into educational systems of their countries.

Workshop 5

NATIONAL POLICY — TRANSFER OF TECHNOLOGIES

Supervisor:
P.Waker (South Africa)

The purpose of workshop was to *discuss problems of co-operation of business and industrial circles with the educational sphere for improving the teaching/training systems when applying information and communication technologies.*

It was noted that many countries collide with similar problems when applying new technologies in education, in particular, with overload of curricula, lack of financial, physical and human resources. In addition to this, different countries and different education systems in these countries implement essentially different policy for settling these problems. It was suggested, that those, defining the policy in each education system, accounted for errors and achievements of the other systems. Discussion of successful experience and failures in the policy allowed to develop some proposals for accomplishing more effective policy.

In the course of discussion there was noted the necessity to bring national, regional and international industrial and financial establishments to application of the potential of new information and communication technologies as facilities for expanding an access to education and educational possibilities for various groups of population. State should develop national strategies for introducing information technologies into their education systems, taking account of social, cultural and economic conditions.

There were discussed problems of creating curricula for school. In this process it is necessary to clearly know, who should supply studying information, what general and special purposes should exist. When realising the developed program, one should answer the questions about facts, who should teach, *what* should he teach, *where* should he teach and *when* should he teach; provision should be made for assessing the level of teacher training, carrying selection and distribution of new training equipment, including software. Schools should organise the teaching process in a new way, allowing for specifics of training with the use of new technologies.

The effectiveness of policy in applying new information and communication technologies is determined by a degree of achievement of set purposes, by evaluating the effectiveness of the curriculum and accepted method of its realisation, by a possibility of revealing possible negative consequences and methods of their elimination.

Workshop 6

INDIVIDUAL DISTANCE TRAINING

Supervisor:
A.Meyer (France)

The workshop was arranged for the representatives of French speaking countries with the purpose of discussion of the problems of distance education through modem information and communication technologies

The director of the Centre for Tele-Education (CTE) Dr. Meyer presented his lecture on distance training experience at CTE under National Conservatory of Arts and Trades (CNAM). He reported about major activity directions of the above Centre, about the reasons that resulted in distance training implementation. In particular, he mentioned the fact that the great majority of those people who needs training lives far from cities and cannot use the services of traditional training system. In this case the distance training is the only possible way for solving the problem.

The strategy for distance training depends upon one of the two situations as follows:

- the case when training and learning processes are carried out simultaneously;
- the case when the above processes are separated in time; a teacher has to realize the process of knowledge transfer through a mean or a carrier (CD-ROM, database). This self-training situation invites more active participation of the trainee and thus results in deeper knowledge.

The system for distance training in CTE comprises the following training types:

- individual self-training by means of books and floppy discs;
- team training where great attention is paid to information exchange among trainees;
- distance control and supervision by a teacher;
- distance report and synopsises;
- meetings of teacher and trainees.

The trainees use *TeleSite* software which is unitedergonomic interface providing wide range of services with the purpose of both work with central server databases and connection with a teacher. The above interface is designed as "user-server" system, which is based upon state global computer network.

The TeleSite system was developed for dealing with various pedagogical problems. It can be used under various conditions and with various purposes: for basic training, for continuous training, for professional training at various enterprises etc.

Standard protocols for computer data processing and transfer are used in TeleSite system thus eliminating the barriers for connecting of various institutions to the TeleSite. However, in this case special training of teachers shall be carried out with the purpose of mastering the peculiarities of teaching •under special conditions of distance training. The specialists in the sphere of informatics shall be also retrained.

As far as there is no special distance system for knowledge evaluation in TeleSite, at SNAM the conventional system of exams and tests is used.

Though installation of the system requires serious investments, its servicing is rather cheap (it comprises payments for user's time of telephone line and SSDN computer network during learning data exchange). In the cases when we need constant control of the learning process, i.e. for teaching and tutor's support of several disciplines, for instance of foreign languages the servicing is .comparatively expensive as to high expenses for teachers' salary. In the above case self-learning is not sufficient.

TeleSITE implementation requires that the learners are self-supporting, executive and disciplined. That is why pedagogical support requires serious expenses and efforts in the cases when the groups of learners have low initial level of knowledge.

Similar projects are realized in Mexico and Tunis, and both comparison of these projects and exchange of the obtained experience are desirable.

In conclusion Mr. Meyer emphasised the fact that individual distance learning provides access to knowledge for all need it and improves the following characters of both teachers and learners: skills of self-supporting, excessiveness and discipline, for rational time distribution and information exchange with other learners, skills for information search and selection by means of PC and other skills which are so necessary on the threshold of the third millennium.

Workshop 7

ANALYSIS OF UNESCO / IFIP DOCUMENTS PUBLISHED IN 1994-1995:

PART I : «INFORMATICS FOR SECONDARY EDUCATION - A CURRICULUM FOR SCHOOLS»;

PART II : «A MODULAR CURRICULUM IN COMPUTER SCIENCE»

Supervisor:
Tom J. van Weert (the Netherlands)

For expanding and improving the effectiveness of application of NIT in education UNESCO in cooperation with IFIP have developed two documents, specified in the name of workshop and containing curricula and syllabuses for systems of secondary and higher education, which, in particular, enable to provide deep training on informatics and allow for prospects of its development. The participants of workshop discussed these documents and those connected with them.

It was specified that development of informatics as a *science* permits to apply technological innovations in information and communication technologies (ICT). On the other hand, informatics and ICT depend on processes, occurring in society. Social and technological development define the content of studying the informatics both at the level of secondary school, and at the level of higher education establishments. For countries which just began to develop the informatics and to apply ICT, it is especially important to train skilled personnel with strong information base, which, in its turn, will permit them to use advantages of new approaches to education. The specified syllabuses are developed just for supporting such trends. Both programs enable to accomplish qualitative studying and, beside that, allow for important development tendencies.

It was noted that integration of information and communication technologies expands the possibilities of personality development, and also favours the support of new type of study organisation for every person, as use of NIT leads to development inductive thinking of man, its abilities for generalization, taking decisions, orientation in dynamically varying situation, and also to development of abilities for working in collective, skills in conceptual approaches to problems under complex, various operating conditions.

There was considered interaction of informatics and NIT in education. It was underlined, that informatics is a *science,* having many important applications, which together *comprise technology:* information technology. Owing to importance of such a technology it is necessary to define the subclass of informatics -*Applied informatics.* In so doing, *Fundamentals of informatics* include elements (programming, development of program products, theoretical foundations of informatics, mathematics), which are common for all application programs. During practical employment informatics and information technologies can be combined with the other sciences or technologies, forming so called "information science" or "information technology". "Information and communication technology» serve as an example of such an information technology.

As applied to secondary education, it was pointed out hat for providing the possibility of pupils to work in conditions of dynamically increasing complexity of the world, it is necessary to study them to create dynamic models of real processes. Conceptual programming language appear, which allow to easily model real processes. It was noted that such an approach to programming is reflected in UNESCO/IFIP curriculum for secondary school, which is named there "Modelling with application of subject-oriented programming". All pupils can study application of information technologies by the interactive way in the other teaching subjects, in this case, information technologies serve as power training mean and permit to account for individual possibility of trained persons. Beside that, applied informatics is important when carrying particular tasks or during additional lessons.

When analyzing processes taking place in systems of higher education, it was noted that possibilities of hardware are spread very quickly, however the most important matter is development of software. In some cases it was noticed close connection between sphere of application and informatics, in so doing, models, methods and technology of informatics essentially depend on concrete application. In particular, one of important fields of application are scientific calculations. All these applications are considered in document «A modular curriculum in computer science".

It was expressed a proposal for UNESCO to support organization of workshops for possibility of using UNESCO/IFIP curriculum "Informatics for secondary education» in developing countries.

Workshop 8

LOGICS, INFORMATICS AND EDUCATION

Supervisor:
Yu.V. Ivlev (Russia)

The purpose of the workshop was *discussion of problems of applying logics in computerization of education processes, as well as of role of informatics in teaching logics. There were shown logic means, suitable for modelling thinking processes on computers.*

THEMES OF STATEMENTS:

1. *Training and developing computer games as a foundation for teaching logics in school.* (D.V. Zaitsev, Senior lecturer of Moscow Lomonosov State University (MGU), V.I. Markin, Senior lecturer of the same university, O.Yu. Karpinskaya, Co-president of Council of Fund «Ratsionalist», Russia).

2. *Electronic manual* "Course *of logics».* (V.A. Bocharov, Professor of MGU, I.P. Golovanova, Researcher of MGU, A.E. Gorchakov, Senior researcher of Institute of Geosphere Dynamics of the Russian Academy of Sciences, A.A. Il'in, Engineer of MGU, E.B. Kuzina, N.I. Kiselev, Senior lecturer of MGU, Russia).

3. *Application of systems for automatic search of conclusion for studying logics.* (A.V. Smirnov, Deputy director of Institute of Logics, Cognitology and Development of Personality, Russia).

4. *Application of systems for automatic search of conclusion for studying deductive logics.* (V.I. Markin, Senior lecturer of MGU; A.E. Novodvorsky, Head of group of Institute of Logics, Cognitology and Development of Personality; A.V. Smirnov, Deputy director of the same Institute, Russia).

5. *Experience of teaching logics to philosophers with the use of computer program DEDUCTIO.* (I.E. Gerasimova, Senior scientist of institute of Philosophy of the Russian Academy of Sciences, Russia).

6. *Analytical classification in logics and informatics.* (K.I. Bakhtiyarov, Professor of MGU, Russia).

7. *Cognitive computer graphics and logics of scientific cognition.* (A.A. Zenkin, Leading researcher of Computer centre of the Russian Academy of Sciences, Russia).

8. *Algorithmization of revalent conclusions from formulae of classical logics of prepositions.* (E.K. Voishvillo, Professor of MGU, Russia).

9. *Quasi-matrixes and semantics for limited sets of descriptions of states as a mean for computerization of modal reasonings.* (Yu. V. Ivlev, Head of chair of logic, MGU, Russia).

10. *Proover for calculating preposition (for system of natural conclusion).* (V.A. Bocharov, Professor of MGU; A.E. Gorchakov, Senior researcher of Institute of Dynamics of Geospheres of Russian Academy of Sciences; Mr. E.E. Bolotov, Russia).

11. *Revalent logics and non-monotonous reasonings.* (D.V. Zaitsev, Senior lecturer of MGU, Russia).

12. *Classification of matrixes for implicative logics by means of program MaGIFL 4.* (A.A. Pavlov, Leading software engineer of Institute of Philosophy of Russian Academy of Sciences, Russia).

There were discussed problems of using logics in computerization of educational processes and a role of informatics in teaching logics.

There were presented logic means intended for modelling thinking processes on computers.

It was noted that successful application of informatics in education is in conflict with low logic literacy of teachers and students.

There was shown the role of computer programs similar to program DEDUCTIO, for improving the training process.

It was also shown that existing algorithms of constructing conclusions and prooves for the classical logics of propositions and computer realization of them are of great importance for training purposes.

The participants noted the actuality of problem of wide introduction of teaching logics in secondary school, cited the basic characteristics of a course of logics for secondary school, based on training and developing computer games.

There was suggested to include into Congress Resolution a recommendation about expanding of teaching logics in secondary and higher educational establishments.

Workshop 9

INFORMATION TECHNOLOGIES AND HUMANITIES EDUCATION

Supervisor:
Yu.N. Afanasiev (Russia)

The aim of the workshop was *the discussion on the questions, concerning NIT implementation in the field of art education and presentation of experience of the Russian State Humanitarian University RGGU (Moscow) in the above sphere.*

The following items were discussed:

1. *Information technologies in educational process of the modern humanitarian university.* (Yu.N. Afanasiev, Rector of the Russian State Humanitarian University, Moscow, Russia).

2. *Information resources of library. Library computer system.* (V.Z. Grigoreva, Director of RGGU library, Russia).

3. *Multimedia-technologies in training process of a humanitarian higher educational establishment.*

(Yu.M. Taraskin, Deputy vice-rector of RGGU on application of informatics, Russia).

4. *New principles of teaching and researches on science history with the use of multimedia-technologies.* (S.V. Kuvsninov, Director of "History of science and new education technologies" Centre, Russia).

5. *University information computer network, its information resources and their using in the educational process.* (A.Yu. Semeikin, Vice-rector of RQGU, Russia).

Within the framework of the workshop there was a roundtable discussion: "Information technologies in educational process of modern humanitarian educational establishment". Among the participants of the above event were professor V.S. Anashin, professor N.I. Basovskaya, professor G.A. Belaya, associate-member of the Russian academy of Natural Sciences D.S. Danin, professor V.D. Korolev, professor A.G. Romanenko, senior lecturer D.G. Lakhuti and other.

The discussed problems include informatization of education as a radical enhancement of information resources and technologies. It was noted that one of the topical aims of applying informatics is creation of a new information environment with using of advanced technologies.

The experience was presented of creating and using information environment in the University: information computer library system, multimedia technologies in training process, information computer network.

It was noted that new information environment, being a new form of knowledge, is simultaneously a new form of humanitarian education and completely meets its vital requirements.

The participants backed up a thesis on the dominant contribution into informatization in humanitarian education, including strategy development for humanitarian education as a whole. Besides, the problems of humanization and humanitarization of system of natural-science education were discussed.

On the basis of discussion there were made the following conclusions:

1. The main sense of informatization of humanitary knowledge consists in information freedom, being the condition and simultaneouly form of political and creative freedom.

2. Problem of informatization of humanitary knowledge is the decisive one in selecting the strategy of developing humanitarian education (including of humanitarian higher educational establishment into modern information networks, creating and development of new information technologies during training process of humanitarian higher educational establishment, convergence of research and training processes on the basis of new information technologies).

3. The sharpest social problem is humanization and humanitarization of natural-science and engineering and technical education. Experience of the Russian State Humanitarian University pertaining to the humanities convinces, that in forming new information environment universities play a special role, as they should become information centres.

4. A sharp necessity appears in co-ordination of forces for forming new information environment in questions of creating bases and banks of data and computer training systems.

5. The Russian State Humanitarian University possesses necessary scientific and technical potential for creating co-ordinating centre on forming new information environment in the field of humanitarian education.

It was suggested to include into Recommendations of Congress the following propositions.

1. To ask Secretariat of UNESCO to finance a complex project on predicting alternatives on development of national and international network education, provided advanced network organisation of such a project.

2. By results of the specified project, to prepare the address of UNESCO to governments of States-members with a request to pay especial attention to •development programs and sources of financing for network education; prepare "White Book" on network education, bearing in mind the issue on its basis the international electronic encyclopaedia on network education.

Workshop 10

DEVELOPMENT OF PRE-UNIVERSITY EDUCATION VIA MODERN INFORMATION TECHNOLOGIES AND METHODS

Supervisors:
N.N. Evtikhiev,
N.I. Klyatova,
V.A. Mordvinov (Russia)

The aim of the workshop was the discussion on the questions, concerning the development of university entrants training with the use of NIT, in particular during the process of distance learning.

The following items were discussed:

1. *On the system of distance learning.* (V.V. Verzhbitsky, Chief specialist of the State Committee for Higher Education of Russia, V.D. Shadrikov, Deputy Chairman of this Committee, Russia).

2. On National Report of Russia "Educational Policies and New Technologies" at the 2nd International - UNESCO Congress "Education and Informatics". *(B.A. Sazonov, Deputy Director of Scientific-Research Institute for Higher Education, Russia).*

3. *Activity of the Federation of UNESCO Clubs on Preventive Education of Youth.* (E.B. Balashov, Vice-president of Federation of UNESCO Clubs in Russia, Russia).

4. *"Development and support of system for creative activity of students" — Program of Committee on family and youth affairs at Moscow City Government.*

5. *Telecommunication programme of «New training technologies" UNESCO Club.* (I.P. Deshko, Deputy director of the Centre of New Information Technologies, V.I. Minakov, Head of a department of Moscow City Centre of Creative Activity for Children and Youth, M.V. Kaminskii, President of «New training technologies" UNESCO Club, Russia).

6. *Basic principles of developing teaching-methodical activity of Centre of new information technologies of the Moscow Institute of Radio-Engineering, Electronics and Automatics (MIREA).* (V.N. Tsypkin, Deputy Director of the NIT Centre, MIREA, S.N. Kovalev, Senior lecturer of MIREA, Russia).

7. *NIT application for school and student creative activity in the system of continuing education.* (N.I. Klyatova, Director of Moscow City Centre of Creative Activity for Children and Youth, V.A. Mordvinov, Vice-rector of MIREA, Russia).

8. *New information technologies in training of handicapped university entrants.* (T.Kh. Latysheva, Vice-rector of Moscow Boarding Institute for People with Moving Disabilities on science work, V.V. Popov, Senior lecturer of this Institute, Russia).

9. *Arrangement of the dialog at distance learning.* (N.A. Smirnov, Professor, Russia).

The examples were shown of the activity of Russian higher schools and the institutions on creating system for distance learning of youth, on development and support of creative activity of students.

The activity of Moscow Institute of Radio-Engineering, Electronics and Automatics provides a good example of new approaches to development of training activity with application of NIT. The role of NIT in the field of school and student creative activity for continuing education was demonstrated.

They paid attention to the role of NIT in pre-university training of the handicapped entrants and discussed problems concerning the arrangement of the dialog in the process of distance learning.

Workshop 11

MEDICINE: NEW APPROACHES TO KNOWLEDGE ACQUISITION AND IMPROVEMENT

Supervisors:
O.S. Medvedev, M.Ya. Natenson,
V.I.Tarnopolsky (Russia)

The purpose of the workshop was a *discussion on the NIT implementation in the medical education system. Special attention was paid to «telemedicine» and system of professional development for medical staff at workplaces at backcountry districts and local medical institutions, which is very important for developing countries.*

In the course of the workshop *the following items were discussed:*

1. *«Telemedicine» as a part of informational area of health protection and a method of new medical technologies implementation.* (O.S. Medvedev, Dean of Basic Medicine faculty of Moscow State University, Russia).

2. *New information technologies in medical science, education and practical health protection.* (M.A. Pal'tsev, Rector of the Moscow Sechenov Medical Academy, S.V. Grachev, Vice-rector of the same academy, M.G. Kreines, Supervisor of the Centre of New Information Technologies of the above Academy, A.P. Pogromov, professor, N.N. Repin, Project director the International Scientific Foundation, Russia).

3. *Professional development of personnel dealing with radiation diagnostics on the basis of new information technologies.* (Yu.V. Varshavsky, Chief Radiologist of Moscow, the Head Physician of Diagnostics Centre No 3, Head of the Chair of Radiation Diagnostics of the Russian Medical Academy of Post-diploma Education, Russia).

4. *Modern information technologies in medical service of «Gasprom» JSC.* (V.V. Sidorenko, General director of Health Centre for Gas Industry Enterprises, M.Ya. Natenson, Senior researcher of Institute of space researches of the Russian Academy of Sciences, V.I. Tarnopolsky, Leading scientist of the above Institute, Russia).

The participants ascertained, that active using of computer technologies and modern communication systems started in medicine at present. It is practised in the technically advanced branch of medicine - ray diagnostics. Practically all the medical facilities are equipped with built-in computerized facilities for physician. These computerised facilities, linked together into hospital information networks "and connected, in turn, to global computer networks (of Internet type), create a medical area, bringing together physicians not only inside the hospital but in different hospitals, regions and countries.

This information infrastructure produces perfectly new situation, allowing to settle a number of social and educational problems, as particular:

- a possibility occurs for realising the most important political and social principle for united medical service for a patient irrespective to its social status and residence, owing to the participation of specialists of leading diagnostics and medical treatment centres;
- a possibility occurs for permanent and continuing training and professional development for medical personnel of all professional levels on part time basis. It is especially efficient for diagnosticians who deals with "images". Formerly the transmission of the above «images» with using of trunk lines was either impossible or complicated. Practically only text descriptions were transmitted which resulted in considerable information losses.

During the discussion there were chosen some *main directions connected with training and professional development for medical personnel:*

- realization of the «telemedicine» potentialities and drawing of specialists from leading medical centres for the purpose of consulting and following involvement of physicians to the advanced medical technologies;
- application of information technologies in training medical students and giving students and. physicians an access over computer networks to newest medical information in any medical databases;
- application of new information technologies in post-diploma education and creation of system for continuous professional development on part time training basis;
- application of new information technologies directly in process of medical treatment and diagnostics, including possibilities for specialists to take part in teleconferences, irrespective of place and time of their performance.

The participants of workshop discussed and adopted a sequence of practical measures and recommended to include proposals into the Final Resolution of Congress on the project of creating in Russia a network of medical education, arrangement of medical personnel courses for professional development and mastering practical «telemedicine» as a part of a global «telemedical» network. The possible participants of this project may be Russian medical universities, regional medical institutions connected with them, similar centres in USA and Europe, information structures of towns and industrial companies. Results of this project implementation permit to introduce developed computer information technologies into medical practice in countries of Africa, Asia and Latin America, which mostly need in improvement of the quality of health protection service.

Workshop 12

FORMING INTEGRATED WORLD DATA BASES AND KNOWLEDGE ABOUT PLANETS OF THE SOLAR SYSTEM AND THEIR USE IN RESEARCH AND EDUCATION

Supervisors:
V.I. Tarnopolsky,
M.Ya.Natenzon (Russia)

The aim of the workshop was *the discussion on the questions, comprised creating a world database on Solar System planets for education and researches.*

Programme of workshop included the discussion on the following questions:

1. Integration of planetary information world databases. Strategy of users circle expansion.
2. Structure of databases on planets of Solar System with the aim of their using in education.
3. Application of databases in the university course of comparative planetology.
4. Application of NASA network technology and databases in the general course on Solar System planets.
5. Geo-Informational systems in the course of university training of geographers.

The following participants took part in discussion:

- R. Arvidson - University of Washington, Sent-Luis, USA;
- N.S. Kasimov - Moscow State University, Moscow, Russia;
- R.O. Kuzmin - GEOHI (Russian Academy of Sciences), Moscow, Russia;
- M.Ya. Natenzon - Institute of Space Researches (Russian Academy of Sciences), Moscow, Russia;
- V.I. Tarnopolsky - Institute of Space Researches (Russian Academy of Sciences), Moscow, Russia;
- G. Noikum - Planet Researches Institute, Berlin, Germany;
- N.F. San'ko - Russian Space Agency, Russia;
- F. Shayres - Jet Propulsion Laboratory (JPL), Pasadena, USA;
- T.S. Kirsanova - Institute of Space Researches (Russian Academy of Sciences), Moscow, Russia;
- K.B. Shingareva - Moscow State University of Geodesy and Cartography, Moscow, Russia;
- A.A. Lukashov - Moscow State University, Moscow, Russia;
- Yu.I. Fivensky - Moscow State University, Moscow, Russia;
- W. MacKinon - University of Washington, Sent-Luis, USA;
- Yu.F. Knizhnikov - Moscow State University, Moscow, Russia;
- I. Luriye - Moscow State University, Moscow, Russia.

It was noted that NIT implementation permits to bring leading scientists knowledge and experience nearer to young people and to expand considerably their auditorium. The above possibilities look most topical in the research of Solar System planets, which is comparatively new and promising area for young scientists. That is why this science field (which, in fact, comprises a very thin "cultural stratum") is extraordinary sensitive to interest fluctuations of young scientists. Using of new information technologies allows to optimise the processing of vast information content on planets researches, created by joint efforts of scientists from different countries.

Certain problems have been arisen and caused by imperfection of initially employed information technologies, resulted in the necessity for applying of updated technologies for saving previously obtained scientific data, as a cultural all humanity legacy.

The reported results were related to started international program for creating global computer databases on planetary investigations. These bases allow to save both the earlier obtained data and provide new opportunities of access for users of various levels, beginning from the school one.

The review of materials of workshops is performed by E.A. Manushin, V.A. Galichin (International System Research Centre for Higher Education and Science, Moscow, Russia)
